We may apply the term propaganda to the technics involved in bringing about such a change. Propaganda has been defined as " the manipulation of attitudes by means of significant symbols," and has for its object the arousal of action in specific situations. The most effective modes of propaganda appeal are those which refer to established stereotypes. These take graphic form in pictures and symbols or the written form in slogans. There must always be a certainty that there is some relevancy, i.e., some assumed causal connection between the picture, symbol or slogan and the attitude or stereotype to which the appeal is made. The public health behavior which it is your purpose to establish must be demonstrated in dramatic form, and presented in settings which connect it with the stereotypes and symbols, for example, of success, power and prestige. From the psychological point of view, the function of propaganda and publicity organizations may be generalized as follows: they are concerned with the development of tendencies to action, i.e., attitudes, by the manipulation of significant stereotypes, and the arrangement of satisfying situations which permit the completion of actions thus initiated.

Propaganda campaigns may be divided into three classes:

1. *The campaign may be directed toward already existing attitudes.* Known attitudes of the group regarding childhood, old age, and personal hygiene may be made the object of appeal. The technic in this case consists in associating already established attitudes with new situations. One of the characteristics of human nature is the tendency to infer a causal connection between events or situations experienced together. If Mrs. Astor-Vanderbilt permits her picture to be used in the advertising of a certain cosmetic, the attributes of success and prestige which are attached to Mrs. Astor-Vanderbilt become attached in our minds to the cosmetic in question.

2. *The objective may be the establishment of new attitudes.* Individuals who are neutral or indifferent are usually individuals who have no attitude with regard to the appeals which are made. A basis for the attitudes to be established should be laid in the form of an educational or informational campaign. But such information and education is futile unless it is eventually made the basis for action, that is, unless attitudes are established with regard to it. Not merely authoritative information, sound health instruction, accurate vital statistics, but dynamic, dramatic and systematic propaganda is necessary.

3. *Opposing attitudes must be overcome.* This is the justly famous "sales resistance." In general the technic in this case consists in avoiding rather than antagonizing the resisting attitudes of the groups appealed to.

All propaganda agencies make some assumptions regarding the psychological make-up of the constituency toward whom their appeals are directed. A fundamental problem has to do with the nature and kind of fundamental attitudes which may be assumed to be present in the beginning. Just what are our fundamental attitudes? Here it is necessary to proceed with the greatest caution. Assumptions in this connection based upon armchair speculation are very easy. It is necessary to be realistic about the matter rather than indulge in sentimental assumptions regarding the essential goodness of human nature. Is there a realistic basis for the assumption of fundamental attitudes regarding kindness to animals, affection for children, love of home, desire to be healthy, desire for and interest in good citizenship? As a matter of fact we do not have generalized attitudes regarding these matters, but specific attitudes regarding specific situations, events or people. A detailed analysis of the fundamental attitudes to which public health propaganda should be directed must be based upon careful research to determine the nature of the attitudes regarding public health held by the majority of individuals. Investigation of the results of specific types of response to public health propaganda, together with the study of group attitudes already existing, is absolutely essential to the development of an intelligent and realistic program of public health education. Until research of this type is undertaken, propaganda will be upon a trial and error basis; some of it will succeed, much of it will fail.

There is one fundamental attitude which is sufficiently common to warrant mention. It may be termed the prestige motif in the individual. It is variously called the desire for success, power, domination, or place. It is the attitude toward which much of the most skillful advertising of our day is directed. Why do we wish to avoid halitosis, buy tooth brushes, Life Buoy soap or expensive motor cars? There seems to be a fundamental drive to appear well in the eyes of our fellows, to make a good impression, to be appreciated.

The same appeal and the same attitude which results in the sale of vast quantities of Listerine might be successful in obtaining periodic health examinations. The fundamental features of the American stereotype are embodied in the terms success, domination, efficiency, power, size. The appeal of the beggar on the street and the wistful waif of the Community Chest campaign literature is effective not because they arouse alleged sentiments of generosity or pity for the helpless, but because these figures represent a distressful negation of success, efficiency and power. In a sense, these symbols are effective because they appeal to our desire to escape from that which is unpleasant. If public health programs can be linked with efficiency and success stereotypes, experience has demonstrated that a measure of success is certain.

Examination of public health propaganda literature reveals the fact that the most frequent appeal is to fear attitudes. This may be occasionally warranted, but in the long run it is dangerous, inimical to mental health, and may lay the foundation for the development of specific mental disorders. It may be ineffective also, since we are much more concerned about the state of our prestige than we are fearful regarding the state of our hearts or lungs.

The methods herein described do not depend for their efficacy upon the ultimate soundness or truth of the facts or principles in the interest of which the campaign is conducted. The guaranty that those facts and principles of public health possess a degree of scientific certainty is the only justification for the use of the methods described. The absence of that guaranty reduces public health education to the level of a campaign for the sale of cigarettes.

As a psychologist rather than a public propagandist, I should seriously consider the proposal to conduct a campaign to immunize the public against all campaigns. One of the modes of establishing such immunity would be to establish a vigorous critical attitude in all people regarding the essential validity and the actual realities represented by the campaign hokum, stereotypes, mythological figures and slogans established as a result of high powered publicity. Is the man in the White House really strong and silent? Does the Brown Derby conceal a real democrat? Is there valid statistical proof that a toothbrush drill in schools really reduces the frequency of teeth defects in adults? When the public discovers that there is no fundamental reality to the illusions and stereotypes created by propaganda, an anti-campaign attitude will be set up which will mean the ultimate elimination of all educational propaganda. Therein lies a warning—a warning which, perhaps, it is not the function of the psychologist to voice.

THE WORM TURNS

THE old slogan, " It Pays to Advertise," seems to need some slight revision. For two or three years past, we have been afflicted by cigarette advertisements which were preposterous on the face of them, many accompanied by photographs of movie actors and actresses, baseball and football players, heroes, and—most disgusting of all—a well known Army officer. One brand or the other, as the case may be, wins elections, prize fights, makes statesmen, educators, musicians, or anything else which may seem desirable at the moment. The sad part is that these claims, ridiculous as they are, seem to sell the goods, and at least one company boasts constantly of the increase in cigarette consumption, presumably due to its particular alleged method of treating the tobacco.

The world has at last turned. Naturally the different companies have resented some of the advertisements. There have been movements against the sale of certain brands in restaurants and other public places where sweets are also sold. The candy and sugar manufacturers generally have naturally taken the opposite side, and are pushing their wares, up to the present in an ethical and truthful manner. A number of organizations of national scope, as well as clergymen, physical educators, and welfare agencies, have taken up the fight against the wholesale advertising of cigarettes.

The radio furnishes a means of reaching easily many people; so it is only natural that its services have been enlisted. The most recent movement is a petition to the Federal Radio Commission for the revocation of the licenses of 38 radio stations, located from the extreme North to the extreme South, and from the Atlantic to the Pacific. The petition is based on the grounds that the programs of

a particular tobacco company which are being broadcast are "contrary to public interests, convenience or necessity"; that the object of the advertisement is to transform 20 million growing boys and girls into cigarette addicts; that cigarettes are advised as a substitute for wholesome foods; and harmful diet fads are being encouraged at the expense of health.

Just as the brewers and distillers went to extremes which led to their downfall, so it seems that some cigarette manufacturers are exceeding the bounds of reason and common sense. Whatever differences of opinion there may be as to the use of tobacco by adults, it is universally conceded that its use by adolescents is harmful. The excessive use of cigarettes, combined with the lessening of the appetite and the avoidance of foods which furnish heat and energy, has probably played its part in the increase of tuberculosis noted among young women during the last few years, attention to which has been noted by certain boards of health and statisticians.

PUBLICITY FOR PUBLIC HEALTH

LOUIS E. Schmidt, M.D., Professor of Urology at Northwestern University, Senior Urologist at St. Luke's Hospital, Chicago, Fellow of the American College of Surgeons, Vice-President of the American Public Health Association, just elected member of the Board of Directors of the American Social Hygiene Association, member of leading medical societies in his specialty in this country and abroad, has been expelled from membership by the Chicago Medical Society for "unethical" conduct. The case has attracted national attention in the daily press and in lay and professional magazines, the spur of popular interest being the impression that the action of the medical society was a move against efforts to reduce the cost of medical care.

This is not the place to enter into the merits of the case in its bearing upon an individual. Those who have followed Dr. Schmidt's endeavors through the Illinois Social Hygiene League and otherwise in the campaign to combat venereal disease, and those who have been acquainted with him through professional and personal contacts, have complete confidence that the motives which have animated him have been those of public service and not personal glory or financial gain.

An issue of larger moment transcends the personal aspects. The basis of Dr. Schmidt's removal, the Council of the Chicago Medical Society states, had nothing to do with the cost of medical care, but "rested solely upon a violation of the principles of medical ethics" (Official Bulletin of the Society, April 20, 1929, page 25). The state-

ment then quotes "the principles of medical ethics applicable to the case in question" which refer to publicity, advertising and the solicitation of patients. The Public Health Institute of Chicago, a non-profit organization, has for 10 years been conducting a large and successful pay clinic for the treatment of venereal disease under the management of a board of trustees, composed of leading business men in Chicago, and has employed paid advertising in Chicago papers. Dr. Schmidt has had no direct connection with the Institute, but is President of the Illinois Social Hygiene League, which about a year ago entered into a contract with the Institute, whereby the latter organization paid an agreed sum out of its current surplus to meet the deficit of the League. The Institute also assumed administrative supervision of the charitable clinic conducted by the League.

The advertisements of the Public Health Institute, at least during the last few years, have been directed toward informing the public of the dangers of syphilis and gonorrhea and the need for continued treatment under competent medical direction. The names of no individual physicians have been mentioned in the advertisements. The Institute's name and address has, of course, been given. The members of the lay board of trustees have printed their names in the advertisement as sponsors.

All those interested in public health, whether physicians or not, will unite in condemning the use of advertising or any other form of publicity which is for the profit or aggrandizement of individuals or organizations. The section of the code of ethics of the American Medical Association referring to advertising (Article I, Sec. 4) was extended a few years ago, mentioning "institutions and organizations" as well as individual physicians. The phrasing in this respect is somewhat indefinite. Certainly the public interest demands that there shall be an effective distribution of information concerning diseases dangerous to health, the importance of securing care and that there shall be made known to the public the resources in each locality, in private practice or in organizations, through which adequate attention can be secured.

Publicity of resources for care in venereal disease is especially important, but the principle is fundamentally the same in respect to informing the people about other conditions—tuberculosis, cancer, and diseases of infancy or maternity being examples. Whether publicity is in the form of paid advertising, unpaid news notices in the press, pamphlets, posters or other publications of an organization, seems of little significance, provided the intent is for public service and not for private gain, and that the subject-matter and wording are scientifically

correct, educational and discreet in avoidance of solicitation of patients or exploitation of individuals. The interests of the public health and the increasing demands of the general public for information render it of the highest importance that the code of medical ethics be not interpreted as to hamper properly worded and rightfully motivated publicity.

AN ANNUAL REPORT AND ROMANCE

ANNUAL reports are usually synonymous with boredom. If their subject matter is intrinsically interesting, its treatment frequently dampens the reader's enthusiasm. The appearance of a report which compares more than favorably with an attractive romantic novel therefore deserves special comment. Of all the topics ordinarily uninteresting to the reader, a water supply report is often the dullest, excepting to the enthusiastic technical worker.

Sir Alexander Houston, in the *22d Annual Report of the Metropolitan Water Board of London, for 1927*, escapes the deadening influence of precedent by announcing in the beginning of his report:

> All water supplies in their origin are exquisitely romantic. Water evaporates from the ocean and condenses to form clouds. The clouds burst, and millions of drops of rain, the jewels of heaven, fall on the mountains and hills and valleys to give us our springs, lakes, rivers and subterranean sources of supply. . . . If you love the beauties of nature, simple things like the flow of water from a tap can carry you in imagination to the uttermost ends of the earth; the skies, the oceans and the mountains will be yours; and, if you pause nearer home in your flight, the kindly hills and peaceful valleys, which nurse the water supplies to the great metropolis, will surely gain an intimate place in your hearts.

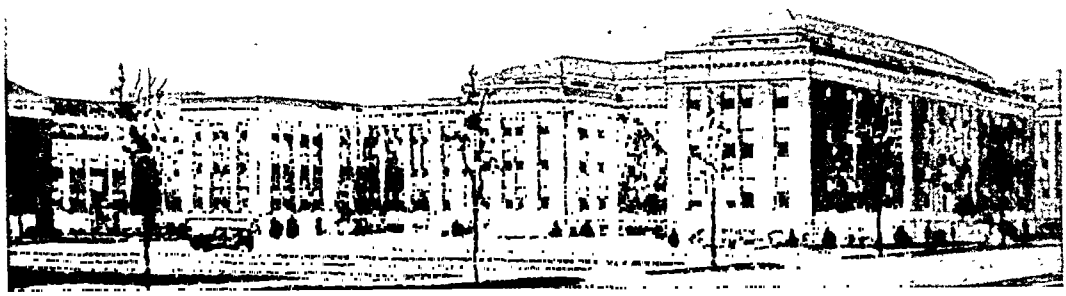
Having thus deliberately escaped from the necessity of presenting his findings in the usual humdrum form and language of annual reports, Sir Alexander then carries his reader through some 80 pages of delightful comment upon water supply problems. And the strange feature of the report is that it contains valuable technical information so frequently and successfully disguised that even a layman might read it from cover to cover.

The report is liberally illustrated with photographs, the effectiveness of which would do justice to any limited edition of our current works of art. Even Sir Alexander, however, feels that he must make apology for producing an entertaining, albeit valuable, annual report. In his review of the upland sources of water supply for the City of London, he graces the pages with such comments as:

Then we reach Harpenden, perhaps the sweetest name in all England, for it means "the valley of nightingales." Miss Ellen Terry, one of the most charming and talented actresses the English stage has ever known, lived for some years at Harpenden. Nearby is the celebrated experimental agricultural station of Rothamsted, whose fame extends throughout the civilised globe. In far distant days, about a mile north, on the borders of the two counties (Hertfordshire and Bedfordshire) many prize fights were fought.

On the same page, however, he apologizes that—

This, however, is a treatise on water supply and some persons dwell in water-tight compartments. The Philistines welcome no digressions; they see only the open road straight in front of them. Perhaps they are right in ignoring all matters not wholly relevant. Others look to the beginning and end of things, the alluring surroundings of a subject, the association of ideas, the belief that there is nothing under the sun which is not related, in greater or less degree, to a thousand other things, which to unseeing eyes may seem to be irrelevant. These are the hill-top worshippers who regard everything in life as wonderful, and who, rightly or wrongly, fail to see why even questions of water supply should be ruthlessly shorn of all the elements of romance, and be regarded wholly and without sentiment as a matter of quantity, quality and financial expediency.



Space is not available to discuss at any greater length the technical matters of importance in this report, but the reader we hope will be allured by the prospectuses so briefly noted above, to review it in its entirety as a beacon light in the dull field of gray-backed annual reports.

PUBLIC HEALTH ENGINEERING SECTION—SCOPE AND POLICY

ATTENTION is directed to the report of the Committee on Scope and Policy of the Public Health Engineering Section published elsewhere in this issue* of the JOURNAL. The duties and responsibilities of the engineering group to the public health profession are clearly stated, the delineation of policies is clean-cut, and worthy of much consideration by other specialized groups of public health workers. Nurses, hygienists, publicists, educators, and laboratory workers all have much the same relationship to the public health field and other branches of their profession as is defined for the engineers in this report. Far-sighted policies of this nature, developed on a carefully planned program, will mean much to the public health profession.

* See page 677.

ASSOCIATION NEWS

PUBLIC HEALTH PAVILION, UNIVERSITY OF MINNESOTA

THE DEDICATION OF THE MINNESOTA PUBLIC HEALTH PAVILION

A PUBLIC Health Pavilion is in process of building on the medical campus of the University of Minnesota. Its completion is planned in season for the Annual Meeting in Minneapolis of the American Public Health Association, the American Child Health Association, and the related organizations of national and state origin, gathering at the same time.

The convention guests have been invited to attend the Dedicatory Exercises on Tuesday morning, October 1, at which the American Public Health Association will assist.

The program will open at the Public Health Pavilion at 9 o'clock on that date, when the guests will be guided in an inspection tour of the new University Hospital buildings. They will then regather at the Public Health Pavilion.

Dr. Lotus Delta Coffman, Chancellor of the University, will preside. He will give the welcoming address and will introduce C.-E. A. Winslow, Dr.P.H., Chief of the Anna M. R. Lauder Department of Public Health, Yale University, who will make the Dedicatory Address.

The gathering will then adjourn to the Cyrus Northrop Memorial Hospital, now approaching completion, where the exercises will be continued.

There Harold S. Diehl, M.D., Chief of the Department of Preventive Medicine and Public Health, of the University of Minnesota, will speak upon "The Evolution of the University Student Health Service."

The concluding address, upon "The Relation of the University to Public Health," will follow, for which the speaker has not yet been announced.

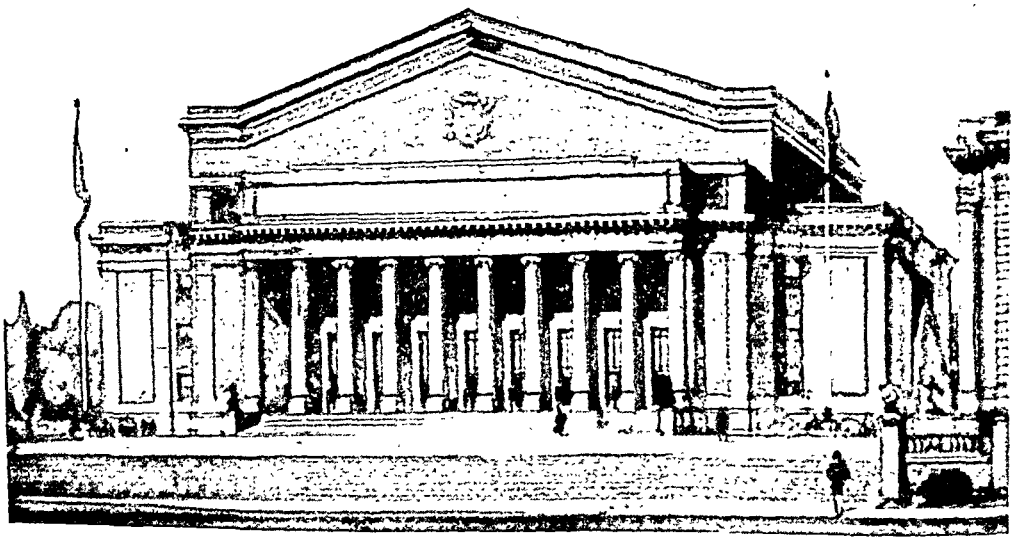
At the close of the program, the guests will be invited to attend a complimentary luncheon in the ball-room of the Minnesota Union, at 12:30 o'clock.

Time will probably permit of a guided excursion through the Main Campus of the University.

Minnesota ranks today as the fourth, in point of registration numbers, of all the great universities of the country, and third among the state universities.

Its college enrollment, for the past school year, was 15,851 and its subcollegiate registration 3,073. The Extension Division and Correspondence

Schools listed 8,790; making a total of unduplicated individuals of 25,895.



On its City Campus are 43 main buildings, housing the College of Science, Literature and the Arts, including the Departments of Animal Biology, Botany and Physics; the College of Engineering and Architecture; the School of Law, the Medical School, including the Central School of Nursing, the Institute of Anatomy, the Cancer Institute, the Todd Memorial Clinic and the Department of Medical Technology; the College of Dentistry and the School for Dental Hygienists, the Departments of Physical Culture, the School of Mines and Metallurgy, the School of Pharmacy, the School of Chemistry, the College of Education, the School of Business Administration, the School of Music, the University Library, the Graduate School, the University Hospitals, and the Administration Services.

At a distance of some three miles lies the Agricultural Campus with its 27 buildings, housing the College of Agriculture, Forestry and Home Economics; the Central School of Agriculture and the Agricultural Experiment Station.

There are Station Schools of Agriculture and Experimental Laboratories at Crookston, Morris and Grand Rapids; and sub-stations at Duluth, Waseca and Zumbra Heights.

The guests of the University of Minnesota will receive a cordial welcome on the University Campus.

NOTE: The Minneapolis Local Committee will be materially assisted if members and guests planning to attend the dedication exercises and to be its guests at the luncheon at Minnesota Union will kindly send their names and addresses to the Executive Secretary of the Committee, 324 Citizens' Aid Building, Minneapolis, Minn., at an early date.

CYRUS NORTHROP MEMORIAL AUDITORIUM, UNIVERSITY OF MINNESOTA

REDUCED RAILROAD RATES

Persons attending the 58th Annual Meeting of the Association and related meetings in Minneapolis, September 30 to October 5, will be granted a rate of one and one-half times a one way fare by the railroads from the starting point to Minneapolis and return.

To obtain the reduced rate it is necessary to obtain from the ticket agent a reduced fare certificate when purchasing your ticket for Minneapolis. Do not purchase your return ticket. This reduction is available to all delegates and members of their families attending the Annual Meeting of the American Public Health Association and meetings of the following related organizations:

American Child Health Association
American Social Hygiene Association
International Society of Medical Health Officers
Northwest Conference of Child Health and Parent Education
Minnesota State Sanitary Conference
Minnesota State Public Health Association
Minnesota State Organization for Public Health Nursing
Conference of State Sanitary Engineers
American Association of School Physicians

Ask for a certificate for the meeting of the A. P. H. A. and related societies. This certificate when validated by the Executive Secretary of the A. P. H. A. at the Minneapolis meeting will entitle the purchaser to a return ticket at half fare.

Detailed information regarding railroad rates and transportation will be sent to all members of the Association and related societies the first week in August.

RAILROAD RATES FROM VARIOUS CENTERS TO MINNEAPOLIS

	Regular Rate One Way	Special Rate Round Trip	Lower Berth	Upper Berth
Atlanta, Ga.	$41.13	$ 61.70	$10.88	$ 8.70
Baltimore, Md.	42.44	63.66	12.00	9.60
Boston, Mass.	50.90	76.35	12.75	10.20
Buffalo, N. Y.	33.47	50.21	9.00	7.20
Chicago, Ill.	14.66	21.99	3.75	3.00
Cincinnati, O.	24.92	37.38	6.38	5.10
Cleveland, O. (via Orrville)	27.37	41.06	7.50	6.00
Dallas, Tex.	35.50	53.25	12.00	9.60
Denver, Colo.	32.04	48.06	10.13	8.10
Detroit, Mich.	24.47	36.71	6.38	5.10
Indianapolis, Ind.	21.28	31.92	6.38	5.10
Jacksonville, Fla.	53.36	80.04	15.38	12.30
Kansas City, Mo.	17.90	26.85	5.63	4.50
Los Angeles, Calif.	75.99	113.99	23.63	18.90
Louisville, Ky.	24.92	37.38	6.38	5.10
Memphis, Tenn.	31.93	47.90	9.00	7.20
Nashville, Tenn.	30.72	46.08	8.25	6.60
New Orleans, La.	46.11	69.17	13.88	11.10
New York, N. Y.	47.36	71.04	12.75	10.20
Omaha, Neb.	12.69	19.04	3.75	3.00
Philadelphia, Pa.	44.12	66.18	12.00	9.60
Pittsburgh, Pa.	31.54	47.31	8.25	6.60
Portland, Ore.	64.66	96.99	19.88	15.90
Salt Lake City, Utah	49.83	74.75	15.38	12.30
San Francisco, Calif.	75.99	113.99	23.63	18.90
Seattle, Wash.	62.56	93.84	19.88	15.90
St. Louis, Mo.	20.74	31.11	5.63	4.50
Toronto, Can. (via Chicago)	31.98	47.97	9.38	7.50
Washington, D. C.	42.44	63.66	12.00	9.60

Summer tourist tickets, which are on sale from May 15 to September 30 and bear the final return limit date, October 31, are in some cases cheaper than the regular convention fare. This is particularly true of the West. Consult your local agent.

VITAL STATISTICS CONFERENCE

According to an announcement by the U. S. Department of State on April 15, the United States Government will participate in an international conference to consider the revision of international classifications of the causes of death. This conference will take place in Paris in October of this year. The following have been appointed as delegates from the United States: Timothy F. Murphy, M.D., Chief Statistician for Vital Statistics, U. S. Bureau of the Census; Haven Emerson, M.D., Chairman, Committee on Accuracy of Certified Causes of Death and its Relation to Mortality Statistics and the International List, A. P. H. A.; George H. Van Buren, Chairman, Vital Statistics Section, A. P. H. A.; William H. Guilfoy, M.D., Chairman, Committee on Forms and Methods of Statistical Practice, A. P. H. A.;

W. J. V. Deacon, M.D., Chairman, Committee on Vital Statistics Training, A. P. H. A.; Jessamine S. Whitney, Statistician, National Tuberculosis Association; Rupert Blue, M.D., Assistant Surgeon-General, U. S. Public Health Service; Emlyn Jones, M.D., Chief, Bureau of Vital Statistics, Pennsylvania Department of Health; and Edgar Sydenstricker, Milbank Memorial Fund.

MINNESOTA STATE SANITARY CONFERENCE TO MEET WITH A. P. H. A.

At the 27th Annual Meeting of the Minnesota State Sanitary Conference held last month in Minneapolis, the conference decided to hold its 28th Annual Meeting at the time of the 58th Annual Meeting of the A. P. H. A. in Minneapolis, Minn., the week of September 30, 1929.

ARIZONA PUBLIC HEALTH ASSOCIATION

The Arizona Public Health Association held its meeting in Prescott, Ariz., April 16 and 17. The following were elected officers for the ensuing year: *President,* Harry T. Southworth, M.D., Prescott; *First Vice-President,* George Grove, Tucson; *Second Vice-President,* Arthur J. Kline, Prescott; *Secretary-Treasurer,* Jane H. Rider, Tucson; *Executive Committee,* H. A. Reese, M.D., Helene Thomas Bennett, W. J. Jamieson and G. F. Manning, M.D.

The association indorsed the invitation of the Texas Association of Sanitarians to the American Public Health Association to hold its 1930 convention in Texas.

DEATH OF EDITH HEDGES MATZKE

Edith Hedges Matzke, M.D., died very suddenly on April 7 at the Stanford University Hospital in San Francisco.

Dr. Matzke obtained her degree of M.D. at the Women's Medical College of Pennsylvania and her degree of Dr.P.H. at the School of Medicine, University of Pennsylvania. During her professional career she was associated with the following institutions: Stanford University, Cornell University, Inter-departmental Social Hygiene Board; University of Missouri, Women's Medical College of Pennsylvania, and the Health Clinic of College Hospital, Philadelphia, Pa. At the time of her death, she was actively engaged in private practice in San Francisco, Calif.

Dr. Matzke was a Fellow of the American Public Health Association and of the American Medical Association and a Collaborating Member of the American Social Hygiene Association. Previously she took an active part in the State Medical Societies of Pennsylvania, New York, Missouri, and California.

ASSOCIATION DELEGATES TO INTERNATIONAL CONGRESS

The American Public Health Association appointed as delegates to the International Congress of Public Health held in Zurich, Switzerland, May 15–20, Francis E. Fronczak, M.D., Commissioner of Health of Buffalo, N. Y., and Benjamin S. Stephenson, M.D., Health Commissioner of Shelby County, O.

TUBERCULOSIS CLINIC RECORD FORMS

The Sub-Committee on Record Forms of the Committee on Administrative Practice of the A. P. H. A. has prepared for distribution sample copies of a set of 5 tuberculosis record forms which may be considered as minimum standard forms.

The set consists of a family folder which affords space for recording the make-up of the family, a medical examination form for recording the individual medical history of each patient on his first visit to the clinic, a reëxamination form, a monthly report form, and an index card which contains

enough information to be usable as the basis of the monthly report.

The index card takes the place of the old fashioned ledger or day book, which can be dispensed with. Copies of this tentative set of forms may be obtained by writing to the American Public Health Association.

NEW MEXICO PUBLIC HEALTH ASSOCIATION

The Fifth Annual Meeting of the New Mexico Public Health Association was held at Carlsbad, N. M., May 2–4. The following were elected officers for the coming year: *President,* James R. Scott, M.D., Albuquerque; *Vice-President,* Edith Hodgson, R.N., Santa Fe; *Secretary-Treasurer,* Paul S. Fox, Santa Fe.

The association passed a resolution endorsing the Standard Milk Ordinance of the U. S. Public Health Service and recommending that the State Board of Public Welfare give its endorsement to this ordinance and urge its adoption by all larger municipalities in the state.

NEW MEMBERS

Edgar F. Allen, Elyria, O., President, International Society for Crippled Children (Assoc.)

Helen A. Bigelow, R.N., Fulton, N. Y., Public Health Nurse

Henry F. Burt, A.B., Providence, R. I. (Assoc.)

Dorothea Campbell, Charleston, W. Va., Director, Bureau Public Health Education, State Department of Health

Thomas H. Chesnutt, M.D., Moultrie, Ga., Commissioner of Health

Josephine L. Daniel, R.N., Jefferson City, Mo., Field Demonstration Nurse, State Board of Health

Vernon A. Douglas, M.D., Salem, Ore., City-County Health Officer

Louise E. Drake, B.S., Athens, Ga., Director of Health, State Teachers' College

Charles H. Eastwood, Jacksonville, Fla., Public Health Engineer, Wallace & Tiernan Co., Inc.

Leo F. Ey, Columbus, O., Acting Chief, Division of Laboratories, State Department of Health

Cameron St. Clair Guild, M.D., Tupelo, Miss., Director, County Health Department

Lillian R. Hamrick, Charleston, W. Va., Staff Nurse, Kanawha County Health Unit

Beatrice A. Harvey, R.N., Gering, Neb., School Nurse

Alma C. Haupt, New York, N. Y., Associate Director, Rural Hospital Division, Commonwealth Fund

Frank R. King, Madison, Wis., Director, Bureau of Plumbing, State Department of Health

Francis L. Love, Iowa City, Ia., City Health Officer

Joseph S. Maxwell, M.D., Beckley, W. Va., Health Officer of Raleigh County

Jere J. McEvilly, M.D., Little Falls, N. Y., Medical Inspector, Board of Education

Peter H. McNellis, M.D., Los Lunas, N. M., Field Agent, U. S. Public Health Service

Eugene E. Murphey, M.D., Augusta, Ga., President, Board of Health

Margaret L. Plumley, B.A., Chicago, Ill., Research Worker, Julius Rosenwald Fund

Evalina D. Reed, R.N., Provo, Utah, Supervising Nurse, Utah County Health Unit

Dr. George L. Schadt, Springfield, Mass., Laboratory Director, New England Laboratories

Edmund Schreiner, Albany, N. Y., Assistant Director, Division of Vital Statistics, State Department of Health

Byron W. Steele, M.D., Mullens, W. Va., County Health Officer

Eldred V. Thiehoff, M.D., Akron, O., Chief, Child Hygiene Service, City Health Department

E. T. Wetzel, West Union, W. Va., County Health Officer

DECEASED MEMBERS

D. E. Musgrave, M.D., Barboursville, W. Va. Elected member 1921

Ira W. Pickett, Cristobal, C. Z. Elected member 1921

Edith H. Matzke, M.D., Dr.P.H., San Francisco, Calif. Elected member 1921—Fellow 1923

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Summer Camps in Massachusetts—The Massachusetts State Department of Public Health recently asked for a camp licensing law, which failed to pass the legislature. The department is now offering to local health officers and camp authorities minimum standards for the health and sanitary conduct of their camps. These standards have been drafted by a committee of health officers and camp directors and approved by the Massachusetts Association of Board of Health, the New England Camp Directors Association, and the Massachusetts State Department of Public Health.

Every camp should be provided with a water supply of good sanitary quality and of sufficient quantity. Where available, flush toilets should be used. Where this is impossible, camps should be provided with suitable equipment for the disposal of sewage. No privy or receptacle for sewage or garbage should be located within 200 feet of any well or spring. The location of all sanitary conveniences should be clearly indicated to tourists. There should be proper receptacles for garbage, rubbish and other refuse. All living quarters, dormitories, kitchens, etc., should be properly screened. There should be a caretaker in charge.

For organizational and private camps, medical supervision is recommended, including a complete physical examination for each camper before starting for camp. Where there is no resident physician, arrangements should be made with at least two neighboring physicians to supply professional service when needed. There should be evidence of successful vaccination against smallpox, and typhoid fever immunization should be urged. Negative stool and urine specimens and a Widal should be required of the entire food handling personnel. All under 15 years of age should have a Schick test before going to camp, and active immunization is urged for all positive reactors. There should be daily medical inspection at camp and careful observation during the two weeks immediately following the opening of camp. The director should impress on the minds of the campers the dangers of contracting typhoid fever by drinking casually from brooks and ponds which are not known to be safe. Visiting should be limited as far as practicable. All milk used should be adequately pasteurized. So far as possible physical defects should be corrected before going to camp. There should be proper supervision of rest periods and courses of exercise. A definite food service is recommended incorporating a well balanced and healthful diet.

Diphtheria Prevention in New York City—The diphtheria prevention commission of the Department of Health in the City of New York has prepared, with the coöperation of the Milbank Memorial Fund, a book, *How to Protect Children from Diphtheria—A Handbook of Information*, which outlines the program inaugurated January, 1929. This booklet, copies of which can be obtained from Shirley W. Wynne, M.D., Commissioner of Health, is of historical value in that it outlines the progress of diphtheria control work in New York over a period of years. It contains numerous reproductions of

editorials which have appeared in the various newspapers. A list of stations at which immunization may be secured by parents is also included.

Inconsistent Hospital Death Records—The importance of accuracy in death records and statistical surveys should be apparent to everybody, and also the fact that misstatements are frequently worse than no statement at all.

In connection with a statistical survey of cancer prevalence in Pennsylvania, the hospitals of this state were requested to report the number of deaths from cancer occurring in such institutions during 1927. Seventy-four of the 239 institutions replying to the questionnaire gave the desired information, and in this group the original death certificates indicated 18 per cent more deaths from cancer than acknowledged on the questionnaire. Additional information was obtained by personal visit to the hospitals of Philadelphia and Pittsburgh, increasing the number of reporting institutions to 117, of which number 67 reported 411 fewer and the remaining 50 claimed to have 107 more cancer deaths than the original certificates indicated.

These discrepancies indicate the danger of placing too much confidence in data collected by the questionnaire method and suggest a lack of dependence upon such system for formulating definite conclusions. The inaccuracies were due to incomplete hospital records, to irregular methods of keeping such records, or to guesswork by the hospital record clerk in supplying the needed information. In a few instances the discrepancies were due to the selective methods of statistical practice in classifying causes of death. For instance, a man with intestinal carcinoma may be regarded by a hospital as dying of appendicitis or intestinal obstruction, but his death when classified by a statistician may be placed among the cancers. For purposes of statistical classification cancer is given preference over such important diseases as diabetes and tuberculosis, which might be regarded by hospital physicians as the actual cause of death.

Hospital records will show more deaths in hospitals than the state records, when the persons who make out the death certificates fail to put down the name of the hospital. This omission has been found to occur frequently. Hospital executives should be informed that all birth and death certificates used for hospital patients should be made upon blank forms kept in such institution. The name of the hospital should be distinctly written or printed on all blank certificates previous to their use. The diagnoses as recorded on the death certificates should correspond with the diagnoses entered upon the hospital records and in all instances the recorded information should be complete.—Harold B. Wood, M.D., Epidemiologist, State Health Department, Harrisburg, Pa.

LABORATORY

C. C. YOUNG

A COMPARISON OF SEITZ AND MANDLER FILTERS

N. W. LARKUM, PH. D.

Michigan Department of Health, Lansing, Mich.

ONE of the interesting and significant phases of the trend of bacteriology during the past ten years has been the emphasis placed upon filtration as a means of removing bacteria from fluid media. The study of bacteriophagy, the investigation of bacterial life cycles, the isolation of viruses, and the preparation of media, of antigens, and of antiviruses, have involved the use of filters to such an extent that apparatus of this kind must now be considered as an essential item in the equipment of a laboratory. In view of this fact, the selection of filters becomes a problem of some magnitude, which at present cannot be settled by the consultation of literature.

Although much valuable investigation of the physico-chemical properties of filters has been published, such reports have little direct application to the question of choice between several types of filters listed by supply houses. As a matter of fact, until quite recently there was probably little to influence one's choice. The advantages of one type were offset by its disadvantages and the issue was decided by the previous experience of the user.

The introduction of the Seitz filter, if the claims of the manufacturers and distributors can be accepted, has upset this equilibrium. So great is the apparent advantage of this filter that for many purposes it should entirely replace other types. The claims are based upon several published articles which, however, are not conclusive. They do justify a more careful and complete study. Such a study has been made, largely by comparison of Seitz and Mandler filters. The results are summarized and presented here.

The great advantage of the Seitz filter is that it is used once and discarded, thus obviating the necessity for cleaning and avoiding the difficulties attending incomplete removal of the chemicals used. Against this advantage must be checked the cost of sterile filtrate produced. Such a study entails a knowledge of the life of a Mandler filter and of the amount of sterile filtrate which a Seitz and a Mandler filter will yield. The former question is difficult to study by direct methods since it is obvious that too many factors must be taken into consideration.

Experience over several years during which Mandler filters 1″ x 3/8″ were largely used furnishes a basis for estimate which has been checked by a limited number of experiments. The average life of a Mandler candle of this size is about ten filtrations, irrespective of the amount of material filtered. There are individual candles with much longer lives, and there are many that are used after they should have been discarded. Certainly the bubble test as an indication of the value of a candle in giving a sterile filtrate is useless. The majority of candles end their career through breakage. Table I shows the record of twelve candles:

TABLE I

MANDLER SIZE 1" x 3/8"

No.	Test	Times Used	Amount Filtrate Sterile	Total	Fate
1	8 lbs.	8	1,400 c.c.	4,600	Broken
2	8	3	2,597 *	3,584	Broken
3	8	4	1,103	4,210	Discarded—leak
4	8	3	1,430	4,380	Broken
5	5	3	0	1,547	Discarded—no sterile filtrate
6	6	12	3,120	6,000	Broken
7	6	11	2,117	5,888	Discarded—leak
8	6	1	0	1,958	Discarded—poor filter
9	9	4	494	3,284	Discarded—leak
10	9	20	400	400	Still in use
11	9	6	180	180	Broken
12	9	8	240	240	Broken
Total		83	13,081	36,271	
Average		7	160 c.c.	437 c.c.	

* 2,211 c.c. of this total was sterile media before filtration.
Used to check air leaks in apparatus.

Thus an actual record of the life of several Mandler candles checks closely with the estimate. Other workers might obtain somewhat better results although it is scarcely possible that the difference would be great.

The amount of sterile filtrate obtained is not the maximum, for in many instances from 10 to 20 c.c. only were passed through the candle. In order to study this factor, comparative tests of Seitz and Mandler filters were run under identical conditions. Positive pressure was used and samples were collected every few minutes and tested for sterility. *B. typhosus* and staphylococcus were the cultures used. The results are given in Table II.

These figures are subject to considerable interpretation and might be analyzed more extensively than is possible here. The only conclusion that can be reached is that the Seitz equals or betters the record of the Mandler filter with respect to quantity of sterile filtrate. It is of interest to note further that one can depend upon this 20 c.c. size Seitz filter to yield from 100 to 200 c.c. of sterile filtrate. With the Mandler, one guess is as good as another as to the amount of sterile filtrate one may obtain. Again, experience in daily use of such filters checks these findings.

Over several years during which Mandler and Berkefeld filters were used for about ten filtrations daily (average amount of 50 c.c. to each filtration), I found that about 4 per cent of filtrates were contaminated in spite of all precautions. Seitz filters have been used in a similar manner during the past two years, and although the average amount filtered was greater, the percentage of contaminations has been reduced to less than 1 per cent.

Without taking into consideration the factor of time spent in cleaning, comparative costs decidedly favor the Seitz filter. Such costs can only be figured on the basis of cost per c.c. of sterile filtrate. The Seitz filter of the size used here costs $10, subject to discounts. Since, however, the metal parts are practically indestructible, this cost can be distributed over so many c.c.'s as to become negligible. The filter discs are listed 5 cents, subject to discount. One disc gives 390 c.c. of sterile filtrate; so

TABLE II

MANDLER

Filtration	Pressure mm. Hg	No.	Test mm. Hg	No. c.c. Sterile Mandler	Seitz
1	260	9	260	588	389
2	180	9	240	0	13
3	460	9	280	0	109
4	520	12	520	227	232
5	780	12	520	721	810
6	780	12	520	224	242
7	780	12	520	82	493
8	780	12	520	309	214
9	780	13	540	156	462
10	780	13	540	265	133
11	780	13	540	343	215
12	780	13	540	722	585
13	780	13	540	142	367
14	780	14	320	0	573
15	780	15	430	0	133
16	780	15	430	493	862
17	780	15	430	722	584
18	780	15	430	0	608
			Total	4,994	7,024
			Average	277 c.c.	390 c.c.

1 c.c. of filtrate costs less than 0.2 cents. Mandler filters list at $1.25 and have an average life of 10 filtrations. The average amount of sterile filtrate is 277 c.c. The cost per c.c. of sterile filtrate is nearly 0.5 cents. Thus the Seitz filter is about half as expensive as the Mandler. Whether this comparison would hold where larger sizes are concerned it is impossible to state on the basis of these data.

The cheapness of operation is not the sole consideration in the selection of filters. Differences in adsorptive capacities may render a given type unfit for certain uses. Because the composition of the Seitz filter differs from that of the Mandler, it may adsorb substances which the latter does not. So far as charge is concerned, both filters are alike (negative), retaining Victoria blue and allowing passage of Congo red. The Seitz, however, will remove about twice as much dye as the Mandler. Bacteriophage is not affected by passage through the Seitz filter.

The question of rate of filtration is directly associated with the problem of amount of sterile filtrate obtained, for time is certainly a factor in contamination. The statement is made by the distributors that Seitz filters are more rapid than other types. This is true when distilled water is filtered; with turbid fluids there is very little difference. The more rapid the filtration, the more quickly occurs the clogging of the pores and the consequent slowing of flow. If the quantity of fluid to be filtered is less than 50 c.c., there will be a slight saving of time by the use of the Seitz filter.

Another superiority which is claimed for the Seitz filter is the smaller loss of fluid due to retention in the pores. Records of a considerable number of filtrations show that these small filter plates adsorb about 2.5 c.c. of fluid. Some of this may be forced out by continuation of pressure when no visible fluid remains in the filter. This is done at the risk of contamination, however.

The average loss of fluid with the Mandler filter is 4.5 c.c. When small quantities of distilled water are passed through a Seitz disc, size 3, the minimum loss is 1.1 c.c.

Nothing has been said thus far regarding technic, although it is certain that the human factor can considerably influence the results. The writer's technic, so far as Mandler filters are concerned, may be subject to criticism just as is that of many Seitz users who have reported difficulties. The Seitz filter, having fewer parts and no rubber fittings, is decidedly less liable to permit contamination due to errors in technic.

SUMMARY

A careful study of the comparative efficiency of Seitz and Mandler filters has shown a distinct superiority for the former. The rate of filtration and amount of yield have shown some advantages for the Seitz. The adsorptive capacity of the two filter types is essentially identical. For many purposes the Seitz filter is unquestionably cheaper and more satisfactory than the Mandler.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

The Sex Factor in Infant Mortality—During the 10-year period from 1915 to 1924 inclusive, there were from 130 to 134 deaths from all causes among white male infants under 1 year of age, as compared with 100 deaths among white female infants in the U. S. Registration Area. An analysis of white infants in the birth registration area for the years 1918 to 1921 showed a high mortality sex ratio during the first month of life, a rise during the second month, and then a gradual decline in the ratio. It is found that the decrease in the ratio as age increases is due to a decrease in the susceptibility of the male, when the ratios for various groups of diseases are compared at various age divisions. The mortality sex ratio for diarrheal diseases among white infants for the years 1916 to 1921 in the birth registration area was 138 for the first month, 141 for the second month, 136 for the third month and 120 for the tenth to the twelfth months. After the first year of life the ratio continues to fall, so that during the fourth year the death rate for both sexes is about equal. Countries where the infant mortality rate is low have a high mortality sex ratio and those with high rates have a low ratio. Australia with an infant mortality rate of 69 in 1922 had a mortality sex ratio of 120, as compared with Chile, which had an infant mortality rate of 240, and a mortality sex ratio of 106.

Various environmental factors have been found to influence the mortality sex ratio. The relationship between infant mortality rate and the sex ratio in different regions varies. Thus for an infant mortality rate of 80 the sex ratio in England and Wales was 129 for the years 1841 to 1924, as compared with 122 in Sweden for the years 1751 to 1920. The mortality sex ratios for cities tend to be higher than for rural communities. Seasonal variations also occur in the mortality sex ratio. Between 1918 and 1922 the ratio for deaths from all causes showed a rise, starting in November and December, reaching a maximum in February and March, and then falling during the summer months. A similar seasonal

fluctuation occurred for pneumonia and for diarrheal diseases. The pneumonia ratio varied from 143 in February to 115 in August, and the diarrhea ratio varied from 141 in April to 122 in September. It is suggested that the regional and seasonal variations in the mortality sex ratio are dependent on the differences in the amount of sunlight reaching the infant. The greater need of the male infant for sunlight is indicated by his tendency to develop conditions such as tetany and rickets due to the instability of the calcium regulatory system.—Harry Bakwin, *Human Biology*, 1: 90–116 (Jan.), 1929.

All Benefit from Health Work—During the 20 years in which the Metropolitan's Welfare Division has functioned, the mortality of the company's industrial policyholders has declined at a rate twice as great as that in the general population. This is an important achievement; but even more important is the fact that the gain has extended to all age periods of life and to both sexes.

In early childhood, that is, at ages 1 to 4 years, the margin in favor of the insured, although considerable, is smaller than at all later age periods. But after age 5, this margin is very striking. At ages 10 to 14, 35 to 44, and 45 to 54 among males, and 15 to 19, and 45 to 54 among females, the drop in mortality among the insured approximated twice that for the general population. At ages 55 to 64, the improvement among the insured males was five times that shown for the general population, while among females it was more than 18 times as great. At ages 65 to 74, the insured registered substantial declines, although the death rate actually increased in the general population for each sex. It is particularly significant that, whereas the mortality of persons after 55 in the general population has either improved very slightly or has actually increased, the death rate among the insured has shown consistent, substantial declines. It is for this reason that the expectation of life of the insured, at the higher ages, is still increasing, while that of the general population stays near the earlier level.—*Stat. Bull.*, Met. Life Ins. Co., 10: 7–8 (Mar.), 1929.

An Inquiry into Asthma—An analysis was made of the records obtained from 404 patients suffering from asthma who were investigated by the Royal Infirmary of Edinburgh during the past 8 years. The first appearance of asthma was before the age of 20 in over 50 per cent of the cases. Of 139 cases in whom inheritance of asthma was noted, 59.6 per cent began to have the disease before the age of 20. Over 80 per cent of the patients were suffering from some respiratory infection just before the asthma started. Seven per cent of the patients had suffered from digestive disorders, 12.6 per cent from nasal conditions, 4.6 per cent from psychic disturbances, and 5.7 per cent from skin disease. Exposure to dust was recognized as an aggravating factor by 48 per cent of the cases. In about 13.5 per cent of the cases, asthma was due to exposure to pollen. Protein skin tests were tried out in 300 patients, and 50 per cent of these gave positive results. About 35 per cent of the patients stated that their attacks of asthma were quite independent of the weather. Among 65 per cent, cold and damp appeared the most likely weather condition to bring on the disease, and about 18 per cent of the cases objected to dry or warm weather. A certain proportion of the patients found that their asthma was definitely seasonal, the majority of the asthmatics being worst in winter and summer. Among 101 cases, the first onset of asthma was in the winter, among 90 cases in summer, among 63 in autumn and among 61 in spring. Nineteen per cent of the patients claimed

their asthma to be worst when at the seashore, 14 per cent when in the country, and 11 per cent when in the city. Psychic disturbances such as fright, worry or emotion induced attacks in 40.6 per cent of the cases. Of 112 females of active menstrual age, 46 per cent found their asthma worse at, or just before the period. Examination of the nose and throat was carried out in 299 cases on first reporting at the hospital. Nasal abnormalities were present in 63.1 per cent of the asthmatics examined.

The analysis of the case records has demonstrated the enormous importance of respiratory infections in the production of asthma in this district. It has also shown that the tendency to develop the disease at different periods of life is more uniform than was previously supposed.—*Lancet*, 1: 517–518 (Mar. 9), 1929.

Health of the American Indian—There are approximately 350,000 Indians in this country, and about 225,000 are wards of the government. Medical service has been provided for these Indians by the government since 1873. The general death rate among the Indian population for which there are records is about twice that for the U. S. Registration Area. In 1911 there was an Indian death rate of 35.6 per 1,000 population, as compared with 23.4 for negroes and 13.8 for whites. In 1924 there was an Indian death rate of 22.9, as compared with 17.8 for negroes and 11.2 for whites. Indians have the highest birth rate as well as the highest death rate among the three races. In 1915 there was an Indian birth rate of 35.3 per 1,000 population, as compared with 20.6 for negroes and 25.0 for whites. In 1924 there was an Indian birth rate of 31.5, as compared with 27.4 for negroes and 22.2 for whites. The death rate from tuberculosis among the Indians of the United States is today estimated to be more than four times the death rate from this disease among the white population. This is due in part to lack of racial immunity, unhygienic living conditions, and an inadequate or poorly balanced diet. From July to December, 1927, 25.4 per cent of the deaths among Indian wards of the government were from tuberculosis; 5.7 per cent were from pneumonia; 4.4 per cent were from diarrhea and enteritis under 2 years; and 4.8 per cent from violence. Trachoma has been prevalent among the Indians of the United States for many years. The incidence of this disease varies from 2 per cent in certain states to 20 per cent in groups in the Northwest. The prevalence of venereal disease is reported as slight, and does not constitute a factor in the health situation among most of the tribes. About 10,000 Indians have been vaccinated against smallpox, 4,000 against typhoid fever; and nearly 15,000 children have been protected against diphtheria by the administration of toxin-antitoxin.—M. C. Guthrie, *Pub. Health Rep.*, 44: 945–957 (Apr. 19), 1929.

The Health of Palestine and Trans-Jordania—A report was recently presented to the Council of the League of Nations by H. M. Government, on the administration of Palestine and Trans-Jordania for 1927. Palestine was comparatively free from epidemics of the more serious diseases. There were 1,001 cases of enteric fever with 76 deaths. Dysentery caused 1,782 cases and 31 fatalities. No cases of plague or cholera were reported. One case of smallpox occurred in Jerusalem, and as a consequence 34,000 inhabitants underwent vaccination. There were 3,305 cases of measles resulting in 324 deaths. The estimated population for 1927 was 778,369. There was a

birth rate of 50.4 per 1,000 population as compared with 53.5 in 1926. The highest birth rate of 56.1 occurred among the Moslem population, and the lowest of 35.1 among the Jewish. The general death rate was 28.0 per 1,000 population, as compared with 24.4 in 1926. There was an infant mortality rate of 201 per 1,000 live births. The highest rate of 217 occurred among the Moslems, as compared with the lower rate of 116 among the Jews.

In Trans-Jordania there occurred 66 cases of enteric fever with 6 deaths during 1927; 34 cases of influenza with 6 deaths; 66 cases of dysentery with 2 deaths; 154 cases of measles with 30 deaths; 37 cases of pneumonia with 7 deaths, and 14 cases of erysipelas with 1 death. There were single cases of smallpox and diphtheria which were imported. The steps taken to protect water supplies from contamination noticeably reduced the incidence of enteric fever and dysentery.—*Lancet*, 1: 592 (Mar. 16), 1929.

Gall-bladder Disease—An analysis from the standpoint of postoperative results was made of 109 cases of gall-bladder disease operated on at the Free Hospital for Women, Brookline, Mass., between 1905 and 1926. Tuberculosis and cancer were each found in 6.4 per cent of the family histories. Seventy per cent of the patients had undergone operations of some kind. Typhoid fever was found in 11 per cent of the past histories, and gall stones had been noted present in 8 patients at previous operations. Ninety-two and six-tenths per cent of the patients were married, and 83.5 per cent of these had borne children. The onset of symptoms of gall-bladder disease was definitely related to pregnancy in 18.6 per cent of these patients. The predominant age of onset was found to be from 25 to 40 years, and the majority of operations were performed between the ages of 30 and 45 years. The duration of symptoms in most cases covered a range of from 1 month to 21 years. No deaths occurred among the 109 patients submitted to operation. In 80 per cent of the cases the convalescence was uneventful.

A follow-up of the cases brought information from 72.5 per cent. Sixty-eight of these had postoperative intervals of at least 2 years, 49 of 5 years, 42 of 8 years, 29 of 10 years, and 17 of 12 years. Ten deaths were reported, none of which was directly traceable to operation. Complete relief from symptoms was reported by 60.8 per cent of the patients, more among those with cholecystectomy than cholecystostomy. Twenty-eight per cent had occasional digestive upsets, and 11 per cent reported recurrence of typical gall-bladder attacks. Inability to eat certain foods, especially fats and fried foods, was reported by 19 per cent of the cases. Five per cent had symptoms probably due to obstructing adhesions. Twenty-five patients reported gains in weight of from 10 to 65 pounds. Twenty patients stated that there were no hernias in the gall-bladder scars, and two reported some bulging in that region. Fifty-seven cases failed to mention hernia.—George A. Marks, The Late Results of Operation in 109 Cases of Gall-Bladder Disease, *New England J. Med.*, 200: 587–592 (Mar. 21), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

SCOPE AND POLICY *

PUBLIC health engineering may be defined, briefly, as the practice of those engineering arts which affect public health, or, more elaborately, as the application of the laws of science, including those of physics, chemistry, and biology, to the betterment of man's environment. One of the best descriptions of the field of public health or sanitary engineering may be found in the address given by Harrison P. Eddy before the Sanitary Engineering Division of the American Society of Civil Engineers. After reading this, one is better able to visualize the intimate relationship between engineering practice and the improvement of the public health.

It has been a long time since public health work was exclusively of a medical nature and it would be as absurd to expect a man with only one kind of training to be proficient in all kinds of public health work as it would be to expect a modern priest to heal wounds and build bridges as did his ancient prototype.

Specialization in public health work has been growing; the present make-up of this Association indicates that growth and its diversity better than anything else. During the latter part of the last century, there were in the Association but few chemists, bacteriologists, social workers, or vital statisticians, and there were no nurses nor child hygienists. Meetings were rather formal and the subjects discussed now seem odd. Nevertheless, the quality of the workers and the work done were excellent and we look back with pride upon the early meetings.

The laboratory workers were the first to form a section; then came the others in turn until we now have a number of groups of specialists.

It should be the paramount aim of each section to serve not only its own particular group of specialists but also the Association. One of the principal ways in which the Association may be served is by extending to the groups in other sections sources of information, thereby permitting them to benefit. On the other hand, the engineers making up this section should be expected to benefit by their contacts with those who are primarily interested in administration, medical, or educational phases of public health work.

It is, therefore, an important function of the Public Health Engineering Section to conduct its meetings so that the results of engineering work may be presented to the lay and professional members of the association in an understandable manner. This means that this section is not the place for papers on hydraulics, mechanics, or details of engineering construction, but for those which connect engineering methods and accomplishments with public health work.

Engineering societies, associations of water works men, and sewage works associations offer the best outlets for technical papers in those fields. This sec-

* Progress report of the Committee, presented at a Luncheon Session of the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

tion's meetings should be the place for interpretive and educational papers on the relationship between the engineering arts and the improvement of the public health.

The field of work of the members of the Conference of State Sanitary Engineers is very closely related to that of the members of this section, and it is the hope of the committee that in the future the meetings of this Conference may be more closely associated and coordinated with those of this section.

Even with the relegation of highly technical papers to other associations, there still remains a group of engineering subjects which need consideration and which have no forum other than this section in which they may be presented. The committee refers here to such works as drainage, shellfish sanitation, rat extermination through better building construction, ventilation, housing, and others. Until these lines of work develop to where each has its own parent association where it may be discussed, this section should provide for the proper expression of results of work in these respective fields.

Some thought should also be given to the desirability of preparing manuals of practice, like the *Standard Methods of Water Analysis* fostered by the Laboratory Section. Although there seems to be no particular need for this work at present, the future may indicate the necessity for such manuals of procedure.

It is only rarely that the engineer becomes a mouthpiece of public health information. That function should be relegated to other workers, such as the health officer or the teacher, both of whom come in direct contact with the public; whom the public understands; and to whom it looks for authoritative information. The assumption of this attitude does not place the engineer in a position of servility, nor does it cause the loss of any professional dignity, for no one recognizes the contributions of engineers to the improvement of public health or is more dependent upon engineers for counsel and assistance than the modern conscientious health officer.

The scope of activities of this section, therefore, should include the zone where engineering borders upon public health and the policy should be to serve its members daily by informal contact, and the Association by bringing engineering results and methods into public health work and to the attention of public health workers.

That such service will benefit the server even more than the served is the experience of the human race.

Lethal Effect of Chloramine on Mosquito Larvae—The subject is dealt with from the water purification point of view, but the investigations cover only rain water with a single species of larva. The primary object of the tests was to ascertain if it were possible to eliminate larvae from a water by means of chemicals without affecting its potability. Tables of concentrations and the effects of chloride of lime and ammonium sulphate, applied together, and of other chemicals are given. The results show that (a) it is possible to kill mosquito larvae in a water by means of chemicals which are ordinarily used in water treatment; (b) in a water chemically very impure, mosquito larvae (*C. pipiens*) are killed in 24 hours by a concentration of 1 in 50,000 (expressed as Cl) of a mixture of chloride of lime and ammonium sulphate; (c) if such

treatment is followed by the addition of sodium hyposulphite, the water has no obnoxious odor or taste; (d) with chemically purer waters, lower concentrations of chloramine would be effective.—B. A. Adams, *Med. Off.*, 65, 1928. (From papers of Water Pollution Research Board, England.)

Purification of Sewage Containing Large Amounts of Dyestuffs by the Activated Sludge Process—Laboratory experiments show that the activated sludge process is capable of removing the septicity of sewage containing dyestuffs but that the complete removal of the dyes necessitates other means of purification, such as filtration through clinker.—Pritzkow and Jordan, *Wasser u. Gas.*, 18: 553, 1928. (From papers of Water Pollution Research Board, England.)

Bacterial Pollution of Bathing Beach Waters in New Haven Harbor—A study was made of the pollution of water in the New Haven harbor at bathing beaches. Eleven sampling stations were established on the West shore, 3 in the Quinnipiac River and 16 on the East shore. Samples were collected at each harbor station on eleven different days in the period from November, 1926, to April, 1927.

There is a sketch of the harbor showing location of the sampling points. All samples were (a) plated on plain nutrient agar for incubation for 48 hours at 20° C.; (b) plated on eosin-methylene-blue agar for incubation for 36 hours at 37° C.; and (c) inoculated in 0.1 and 0.01 c.c. dilutions of lactose broth for incubation at 37° C., and subsequent examination of tubes showing gas for *B. coli*.

The results are recorded in tables for comparison at the various stations. The direction of the wind is given as the chief factor in the pollution of these bathing beach waters.

Among the conclusions drawn are that the bathing beach waters of New Haven harbor are highly polluted and at certain points are so heavily polluted as to be manifestly unfit for bathing. A comparison is made in this article between the results of this study and the limits set by the Conference of State Sanitary Engineers and the standard generally accepted in the State of California.—C.-E. A. Winslow and David Moxon, *Am. J. Hyg.*, 8, 3: 299–310 (May), 1928. Abstr. A. L. Dopmeyer.

Contribution to the Knowledge of Sewage Chlorination—A study has been made of the effect of chlorination on the subsequent biological purification of sewage at a small suburban sewage disposal plant at Nürnberg. This consists of septic tanks and a percolating filter, and recently, owing to an increase in population, it has been considerably overloaded. In order to avoid extending the plant, which will shortly be superseded by a larger central works, a chlorinator was introduced before the percolating filter. The dose applied varied from 15 to 25 p.p.m. The effect of chlorination was to remove the odors, prevent the clogging of the filter and reduce the septicity of the final effluent. The oxygen demand of the filter influent was reduced by 14.3 per cent. The biological purification effected by the percolating filter, as measured by the reduction in permanganate and biochemical oxygen demand, was not, however, increased by chlorination.—E. Merkel, Paper read before Verein deutscher Chemiker, *Chem. Ztg.*, 52: 451, 1928. (From papers of Water Pollution Research Board, England.)

Chlorinated Copperas—A New Coagulant—Elizabeth City, N. C., takes water from Knobb's Creek and is facing the problem of reducing the color from 150 to 550 p.p.m. in the raw water to 7 to 10 p.p.m. as delivered to

consumers. The color is present as negatively charged colloidal particles as determined by dialysis and cataphoresis. A modern rapid sand filtration plant was ineffective.

Summary and conclusions: (1) Copperas (ferrous sulphate) and lime are not satisfactory coagulants at Elizabeth City, N. C., unless the copperas is oxidized to its ferric state; (2) prechlorination with reasonable doses does not improve coagulation of the highly colored water at Elizabeth City, N. C., when applied in the mixing chamber; (3) prechlorination reduces the tendency of the sludge in the coagulation basins to ferment; (4) single coagulation with any of the coagulants employed is not satisfactory because of the color and residual coagulant left in the filter effluent; (5) to produce an acceptable filter effluent "split" application of coagulants is essential. The primary coagulation must take place between pH 4.2 and 4.7, and the secondary coagulation between pH 5.5 and 6.5; (6) copperas, completely oxidized with chlorine in the ratio of one part of chlorine to 7.8 parts copperas, produces a coagulant superior to alum in color removal qualities and is more economical because of its higher efficiency; (7) a combination of chlorinated copperas, alum and lime or sodium aluminate produces an attractive and economical filtered water as evidenced by comments of consumers and cost data; (8) conversion of ferrous sulphate (copperas) to the ferric state is readily accomplished by introducing chlorine water from a chlorinator into the discharge line from the copperas feeding machine or solution tank. The reaction between the copperas and the chlorine is practically instantaneous, requiring less than 20 feet of travel for completion.—L. L. Hedgepeth and N. C. and William C. Olsen, *J. Am. Water Works Assn.*, 20, 4: 467–472 (Oct.), 1928. Abstr. C. G. Gillespie.

Iodine in Drinking Waters—In England no such correlation was found between presence of goiter and low iodine content of drinking water as has been reported in Switzerland and the United States. The loss of iodine due to filtration at Aberdeen and Edinburgh was insignificant, but a 50 per cent loss was found in Canterbury water after softening with lime. The mineral waters from Harrogate and Cheltenham have a much higher iodine content than ordinary drinking waters, which may partly account for their medicinal value. The authors caution against two possible sources of error in the determination of iodine in the case of (a) hard waters, and (b) acid mineral waters.—J. B. Orr, W. Godden and J. M. Dundas, *J. Hyg.*, 27, 2: 197–199 (Jan.), 1928. Abstr. A. W. Fuchs.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Legislation in Various Countries Regarding Silicosis with Special Reference to Compensation—The author summarizes the legislation and compensation provisions regarding silicosis in Great Britain for the refractories, metal-grinding and other silicosis industries through the scheme which became operative on February 1, 1929. It is the most comprehensive that has yet been considered and applies to:

> (a) All processes in which dust may be created in mining, or quarrying, or any other form of the manipulation of quartz, quartzite, ganister, sandstone, grit-stone, and chert; but it does not apply to any rock containing less than 50 per cent free silica; (b) Foundries and metal works in processes in which dust arises from (i) articles containing not less than 80 per cent total silica, (ii) fettling steel castings, and (iii) sandblasting with sand, crushed silica rock or flint; (c) Potteries in processes which incur exposure to dust from flint or quartzose sand; (d) Tin mines in processes which incur exposure to dust from the ore or ore containing rock.

The discussion concerns legislation in: the Union of South Africa, with broad provisions; Australia and its component states, New South Wales, Victoria, and Tasmania, in the latter two of which no compensation is granted for silicosis; Ontario, the only Canadian province with legislation definitely naming silicosis (its compensation is somewhat similar to the South African scheme); Alberta, whose Compensation Act of 1925 recognizes miners' phthisis as an industrial disease; British Columbia with a broad act (1925) which does not exclude occupational diseases from compensation, but does not refer definitely either to miners' phthisis or to silicosis; and Nova Scotia of which the same is true.

In the United States, silicosis is not directly named in any law allowing compensation, but the tendency

> . . . is for the language of the laws to be sufficiently broad to cover occupational diseases generally and to allow an interpretation including silicosis. Probably indeed awards for compensation have been made for silicosis as an occupational disease without being named as such in the law of the award, as for example in Wisconsin for irritant dusts.

For federal employees the wording used probably allows an interpretation including silicosis. Silicosis is apparently compensable in the broad acts of California, Connecticut, and Wisconsin. Occupational diseases, including silicosis, are also required to be reported in Maine, Maryland, New Hampshire, New York, Ohio, Porto Rico, and Rhode Island. In Minnesota and New Jersey physicians are called upon to report only diseases included in a definite list which does not include silicosis. No other countries have legislation with regard to compensation for silicosis. (A discussion of 10 pages follows.)—E.-L. Collis, *Rapports,* Apr., 1929, pp. 133–159.

Notes on a Fine Type of Fibrous Pneumonokoniosis Produced by Silicates and Other Minerals—Author's Summary—The etiology is discussed of the fine fibrosis of the lungs which is not uncommonly found in metalliferous and coal miners and some workers in other industrial activities in New South Wales. It is considered that this fine type of fibrosis can in most cases reasonably be assumed to be caused by various silicates. The term " silicatosis " is suggested for the fine fibrosis caused by silicates and the term " sili-

conosis" for a fibrous pneumonokoniosis of a mixed type. The type of fibrosis is considered in workers exposed to orthoclase basalt, coal miners, copper miners, and miners in Broken Hill, Western Australia and Tasmania; iron miners, asbestos and cement workers. The compensation laws of New South Wales relating to pneumonokoniosis are summarized and it is concluded that all fibrous pneumonokoniosis not due to dust containing over 70 per cent of quartz should come under the Workers' Compensation Act, 1926; and the Workers' Compensation (Silicosis) Act, 1920, which provides compensation for diseases caused by silica dust, should apply only to workers who are exposed to dust containing over 70 per cent of quartz.—Charles Badham, *Rep. Director-General of Pub. Health,* New South Wales, for the Year ended December 31, 1927, Section I-E, Industrial Hygiene, Serial Study No. 13, pp. 102–110.

Dust Sampling in Sydney Sandstone Industries—The Greenburg-Smith impinger used in gravimetric sampling was shown to agree with that determined by calculation if the particles are regarded as spheres. The average dust exposure of men using axial water feed drills in tunnels with varying degrees of ventilation has been determined at 110 particles per c.c. In the case of Sydney sandstone masons, the average dust concentration was equivalent to 420 particles per c.c. The Dust Standards of South Africa and Broken Hill (N. S. W.) require not more than 200 particles of less than 10 μ per c.c. of sandstone dust. Counting by the Owens' jet dust apparatus and by the Greenburg-Smith impinger shows both unrivalled for efficiency and ease of manipulation.—Charles Badham, H. E. G. Rayner and H. D. Broose, *Rep. Director-General Pub. Health,* New South Wales, for the Year ended December 31, 1927, Section I-E, Industrial Hygiene, Serial Study 12.

Silicosis among Sandstone Workers—Much fuller and more precise information than had already been obtained was desired about quarrying and stonemasons' work. The areas investigated were 9 in number, scattered from Glasgow to Bristol. Actually, 454 clinical examinations were made, with 266 radiographical examinations. The workers constituted 14 occupational groups and a precise method of securing particulars was followed in each case. A total of 171 *masons* was examined, of whom 116 were X-rayed and 57 found to be suffering from silicosis. Of 65 *rock-getters,* 33 were X-rayed and 13 showed silicosis. Out of 115 *quarrymen,* 67 were X-rayed and 33 showed silicosis. Similarly, 39 *planers* were examined, 23 X-rayed and 5 showed silicosis. The other occupational groups showed much less silicosis.

Of 112 positive cases found, 90 were in the first stage, 21 in the second and 1 in the third (corresponding respectively to the "ante-primary," "primary," and "secondary" terms used in South Africa). Only 1 definite open case of tuberculosis was found, but the inquiries were limited to those who were actually at work, thus preventing a determination of the total amount of tuberculosis present.

The vast majority of workers had been employed on so many different kinds of stone that it was impossible to differentiate effects. (No petrographic or chemical analyses of the stones are given.) Descriptions of 36 different cases are given. Silicosis appeared to become more common after 40 years of age and after 20 years of exposure in the stone industry. (Detailed tables accompany.)—C. L. Sutherland and S. Bryson, *Report on the Occurrence of*

Silicosis among Sandstone Workers. Medical Board under the Refractories Industries (Silicosis) Scheme, H. M. Stationery Office, Adastral House, Kingsway, London, W. C. 2, 1929, 41 pp.

Silicosis in the Pottery Industry—The history of the subject leading up to special powers for dealing with silicosis, the evidences of silicosis in the pottery industry, an outline of the two existing schemes, and proposals for a new scheme are taken up in Part I of this report. It is recommended that the scheme apply to any process in the milling of flint for use in potteries, all processes in the manufacture of potteries and in polishing, grinding and tile-slabbing. However, it is recommended that engine men and stokers and their assistants and workmen employed in modelling and mouldmaking, where carried on in separate rooms, might be excluded. The employers preferred that each employer be made personally responsible for liability in respect of the workers he employs. Both partial and complete compensation are provided for and the provisions of the scheme already in force for compensation in the metal grinding industries (1927) are recommended.

The committee strongly recommends that a special medical board for silicosis cases be set up. "The reasons why the committee prefer the employment in silicosis cases of a medical board rather than a single medical practitioner are fully discussed in their first report. Stated briefly, they are that it is only by a board constituted as indicated, that really satisfactory results can be obtained. The diagnosis of silicosis still presents such difficulties that it is undesirable to leave it to a single officer nor is it fair to the officer to impose on him such a heavy responsibility. Further, it is only by means of a board that uniformity and continuity of practice can really be secured."

Part II consists of detailed regulations for the prevention of silicosis. An appendix includes the report of conferences between medical members of the committee and the medical advisers of the employers and operatives, including some criticism, the questions of diagnosis, radiographic examinations, interpretation of films, classification of the disease, medical examinations and the processes to be included in the scheme. —*Report of the Departmental Committee on Compensation for Silicosis Dealing with the Pottery Industry.* Workmen's Compensation (Silicosis) Committee, Home Office, Great Britain, H. M. Stationery Office, Adastral House, Kingsway, London, W. C. 2, 1928, 41 pp.

The Diagnosis of Silicosis as an Occupational Disease—The paper deals solely with silicosis as it appears in the Gold Mines of Witwatersrand. The criteria adopted by the Miners' Phthisis Medical Bureau have been reached by a careful correlation of the results of pathological, radiographical, and clinical examination in a large series of individual cases. "Silicosis" or "miners' phthisis" as met here is the product of two factors: dust and tuberculosis. The silicotic process precedes and is essentially a progressive lymphatic fibrosis which begins at many points and develops very gradually. The degree or stage of a simple silicosis may be described in terms of the number and size of nodules which are present. In the majority of cases of apparently simple silicosis there is an early element of latent tuberculous infection with certain of the silicotic lesions. While acute infections may be present in the silicotic lung in an unmodified form, chronic infections tend to undergo modification by the production of a

massive infective fibrosis (tuberculosilicosis).

A change of type in the cases of silicosis has occurred in the Witwatersrand, accompanying the measures taken for the reduction of dust in mine air—pathological evidences point to the early presence in the majority of cases of an element of latent tuberculous infection. In fact, the onset of a tuberculous infection may sometimes bring to light latent silicosis. The legal definitions of the stages of silicosis in the Act of 1925 of the Union of South Africa cover the *ante-primary stage,* the *primary stage,* and the *secondary stage* (definitions given). Furthermore, tuberculosis means tuberculosis of the lungs or of the respiratory organs, and a person is deemed to be suffering from the same whenever the Bureau finds either (a) "that such person is expectorating the tubercle bacillus"; or (b) "that such person has closed tuberculosis to such a degree as seriously to impair his working capacity, and render prohibition of his working underground advisable in the interests of his health."

Regarding the monetary aspect, cases in the two earlier stages received "lump sum" awards averaging about £400 for the ante-primary stage, with an additional 50 per cent for the primary stage. Cases in the secondary stage, if resident in South Africa, receive a life pension, with additional allowances for dependents; the average inclusive payment is a little over £200 per annum. Allowances are paid to dependents in case of the miner's death. One important restriction is imposed. If a miner who has been notified that he has silicosis elects to continue work underground for more than 3 months, he forfeits all awards other than that to which he became entitled when first notified. But if eventually he dies from a cause to which silicosis is contributory, his dependents receive their prescribed allowances. The total disbursements for all classes of cases have amounted during the past 3 years to approximately *£1,000,000* per annum.

The clinical and radiographic diagnosis of silicosis is illustrated by a series of 22 radiographs representative of different pulmonary fibroses. A characteristic feature of silicosis in the lungs is that it is a generalized condition. The most reliable single diagnostic criterion is the radiograph, provided that this is of high technical quality and is taken instantaneously, but it must be supplemented by an expert clinical examination. The decision in cases such as silicosis should rest with a specially selected body of medical examiners who have wide experience of the disease, clinical, radiographic and pathological (nine pages of discussion follow).—L.-G. Irvine, *Rapports* (see above), pp. 43–91 (Apr.), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Antigenic Properties of Evaporated Milk—This study was made in an effort to find a more desirable substitute for mother's milk as a food for infants who display food allergy due to sensitization to cow's milk. This investigation is based on the theory that heating certain proteins so changes them that new antigens are formed.

Sensitization tests on guinea pigs and immunization studies in rabbits were made using raw, pasteurized, and evaporated milks. It was found that the milks yielded caseins nearly alike in regard to the minimum quantities of this protein required to produce fatal anaphylactic shock in guinea pigs sensitized to the three types of milk. However, large differences were found when the proteins from whey were compared. The minimum amount of whey proteins from evaporated milk required to produce fatal anaphylactic shock in guinea pigs sensitized to raw milk was 30 times greater than the minimum of whey proteins from raw milk, and it was 40 times greater than that from pasteurized milk in guinea pigs sensitized to pasteurized milk.

The precipitin and complement fixation reactions showed that casein from evaporated milk is very similar to that from pasteurized milk in antigenic activity. There were marked differences in the antigenic properties of the whey protein from the two types of milk. Five times as great a quantity of pasteurized whey protein as of evaporated whey protein was required to produce a precipitate in the presence of serums from rabbits immunized to evaporated milk, whereas when serums from rabbits immunized to pasteurized milk were tested, it was found that approximately 25 times as much evaporated whey protein as pasteurized whey protein was required to produce a precipitate. Approximately the same difference in antigenic properties of the whey proteins from the two types of milk was shown in the complement fixation tests. This indicates a change of specificity whereby heated whey proteins are less reactive in animals sensitized with raw or pasteurized milk, or with antibodies against pasteurized milk.—Oran I. Cutler, *J. A. M. A.*, 92: 964 (Mar. 23), 1929.

Unsuccessful Attempt to Produce Salmonella Intoxication in Man—In order to obtain human experimental data on the problem of whether or not thermostabile toxins, capable of causing illness in the absence of living organisms, are formed by *S. aertrycke* or *S. enteriditis*, 24 people ranging in age from 20 to 40 years were fed heat-killed cultures, or filtrates of cultures, of these two members of the Salmonella group. The 9 strains used had been isolated from food poisoning outbreaks. The heat treatment of the cultures consisted of boiling for 20 minutes in a water bath, and the filtrates were obtained by passing a portion of the culture through a Mandler filter. The cultures used were obtained by incubation for periods varying from 6 hours to 20 days. All the strains used were toxic when injected intravenously into rabbits. The subjects were all fed on an empty stomach, receiving only the culture or the filtrate with a small amount of water. In no case was there vomiting, headache or diarrhea, and there

was no change in blood titer against homologous strains 10 days after feeding. None of the persons fed noted any subjective symptoms.—G. M. Dack, W. E. Cary and P. H. Harman, *J. Prev. Med.*, 2: 479 (Nov.), 1929.

Indian Ephedras, Their Extraction and Assay—Many species of *Ephedra* are known. The Chinese species have been reported to contain from 0.018 per cent to 1.32 per cent of total alkaloids. The American species contain none. This study embraces *E. Gerardiana, E. intermedia,* and *E. foliata*. The first of these contains from 0.4 to 1.25 per cent of alkaloids, the second from 0.1 to 0.3 per cent and the third none. The altitude at which the plants are grown has no effect on the alkaloidal content, but the rainfall exerts a distinct influence; the greater the rainfall, the smaller is the content of alkaloids. The method of extraction employed consists in cold maceration of the finely powdered drug with a mixture of ether (3) and chloroform (1) rendered strongly alkaline with ammonia. This process eliminates the red coloring matter which is present in the stems of the Indian Ephedras and which is extracted by cold alcohol. The liquid is decanted through a filter and the residue treated twice more with fresh solvent. The combined extracts are distilled and the residue is extracted with 1.5 per cent hydrochloric acid until the alkaloids are removed. The combined acid extracts are filtered, made strongly alkaline with potassium carbonate, and the solution almost saturated with sodium chloride. The mixture is shaken 4 times with ether, the bulk of the ether distilled and the residue allowed to evaporate spontaneously. An excess of 0.1 *N*-hydrochloric acid is added and the excess titrated with 0.1 *N*-sodium hydroxide, using methyl orange as indicator.

For large scale extraction of ephedrine, the method found most suitable was extraction of the finely powdered drug with 5 times its weight of cold 0.5 per cent hydrochloric acid. The acid treatment was repeated twice. The mixed acid extract was filtered and neutralized with sodium carbonate till just neutral to Congo, but acidic to litmus. After concentration on the water bath, the solution was made strongly alkaline with sodium carbonate, the precipitate separated and washed with little water, the washings being added to the filtrate. To the filtrate, which contained most of the alkaloids, a large excess of sodium chloride was added and the solution extracted 4 times with ether. The solvent was removed by distillation and the alkaloid residue converted into the hydrochloride by neutralizing with hydrochloric acid. After concentration at 45 to 50° the hydrochlorides crystallized. After drying, the residue was treated with dry chloroform to dissolve the hydrochlorides of other bases, leaving pure ephedrine hydrochloride. A further quantity of ephedrine was recovered from the precipitate, previously removed, by boiling with benzene.—S. Krishna and T. P. Ghose, *Trans. J. Soc. Chem. Ind.*, 48: 67 (Mar. 22), 1929.

Some Comparisons of the Nutritive Value of Whole Wheat Bread and White Bread—White bread and whole wheat bread were compared in this experiment, using albino rats as test animals, to demonstrate their relative nutritive values when they were used as the sole sources of (1) vitamin B complex (F and G), (2) protein, and (3) minerals. It was found that in diets supplemented in respect to other nutrient factors respectively, whole wheat bread was superior to white bread as a source (1) of vitamin G, (2) of protein, and (3) of minerals. Although these experiments have shown the superiority of whole wheat bread

over white bread, it is unnecessary to be concerned over the deficiencies of white bread and discredit its value in the diet, nor is it necessary to advocate the use of whole wheat bread. The dietary habits of the American people are such that any deficiencies of one food item, such as bread, may be amply supplemented by other foods—eggs, dairy products, and vegetables. But where bread constitutes an unduly large proportion of the diet, then the deficiencies of white bread may lead to malnutrition, which could have been prevented by the use of whole wheat bread.—S. M. Hauge and Aneta P. Beadle, *J. Home Econ.*, 21: 199 (Mar.), 1929.

The Mineral Content of Grain—This article is a summation of whole grain analyses made over a 10-year period at the Utah Experiment Station. Figures given are based on analyses of 1,775 samples of wheat, 1,205 samples of oats, 110 samples of barley, and 75 samples of corn. These grains were grown: on both irrigated farms and dry farms; on soils varying widely in composition in respect to "alkali," calcium, sulphur, and gypsum. Determinations were made of ash, calcium, magnesium, potassium, phosphorus, sulphur and iron. The maximum, average and minimum percentages of each of these determinations for each grain are set forth in tables. In general, the figures reported for Utah-grown grains are higher than those previously reported by other workers on grains from other sources. The authors attribute this to the composition of the soil and of the irrigation waters. Using the wheat analyses as a crude measure, the authors estimated the effect of irrigation, soil and variety on the mineral content. For ash, they estimated the extreme variations due to irrigation water to be 46 per cent, variety 31 per cent, and soil 118 per cent. Wheat showed the widest variations and oats the highest average content. Soil, irrigation water and variety caused 600 per cent, 260 per cent, and 200 per cent variations respectively in wheat. Less variation was found in the magnesium content, as irrigation produced 32 per cent and variety 25 per cent. Potassium was found to vary 51 per cent, 35 per cent, and 28 per cent respectively, due to variety, irrigation water and soil. The extreme variation of phosphorus content of wheat was over 300 per cent. Variation in phosphorus content was due to irrigation, soil, and variety. The Utah-grown grains showed a lower phosphorus-calcium ratio which the authors claim make such grains a more nearly balanced food. The sulphur content variations were found to be 48 per cent, 40 per cent, and 30 per cent respectively, due to irrigation water, variety and soil. Sulphur determinations were made by the moist-fusion method, which gives higher results than by ashing. The iron content variation was found to be markedly affected by irrigation water, variety and soil. The authors raise the question whether the factors they report would not materially modify the nutritive value of grains grown on such highly fertile calcareous soils.—J. E. Greaves and C. T. Hirst, *J. Nutrition*, 1: 293 (Mar.), 1929.

The Effect of the Cow's Ration on the Vitamin "D" Content of Milk—As a step in the study of the effect of the cow's ration on the food value of milk, the vitamin D or antirachitic potency of milk from cows on the high-and-low-protein experiment was determined. Since the vitamin C content of feeds used in grain mixtures is negligible, and since all the cows in the experiments received silage, the difference in the vitamin content of the milk was probably due to the kinds of hay used. The high protein and normal cows received alfalfa hay. The low protein cows received timothy hay. The low protein cows also received 1.5 lbs. of

molasses daily. It is concluded that milk from cows fed on a low protein ration that contained timothy hay was slightly more potent in vitamin D than milk from cows fed a high protein ration containing alfalfa hay. Whether this difference was due to the kind of roughage, the manner in which it was gathered and handled to the stage of maturity at which it was cut, or to the presence of molasses in the low protein ration, remains to be determined. The results obtained also indicate that cow's milk is a relatively poor source of the antirachitic factor, at least 23 c.c. of milk (0.8 gm. of butterfat) being required to allow practically normal bone formation in rats fed on a rickets producing basal ration.—W. E. Krauss, *Ohio Agri. Exper. Sta. Bull.*, 14: 57 (Mar.–Apr.), 1929.

The Relation of Soil Fertility to Vitamin "A" Content of Leaf Lettuce—The results reported herein bear upon the question of whether the vitamin A content of plant tissue varies with the conditions of soil nutrition which determine plant development with respect to size and robustness. Lettuce was grown on normal sandy loam soil, on this soil with added sheep manure and a mixture of KNO_3, $CaH_2(PO_4)$ and KCl, and on the same soil with the inorganic fertilizer without the organic manure. This latter lot grew most profusely and with the greatest vigor. Furthermore, the lettuce grown with the inorganic fertilizer only was the greenest of the three lots. Rats were depleted of their store of vitamin A, and when definite losses of fat or xerophthalmia occurred, the rats were fed daily 0.2 gm. of lettuce grown on each type of soil. The animals fed on lettuce raised on the soil treated only with the inorganic fertilizer grew at the most rapid rate and made the greatest gain during the experimental period of 8 weeks. The growth curve for the rats fed lettuce grown with inorganic and organic fertilizer was always below that of the rats fed lettuce grown with inorganic fertilizer only. The rats fed lettuce grown on soil without fertilizer grew more slowly than those in the other two groups. Differences in the growth of the animals on the three grades of lettuce are not explainable through variation in the relative quantities of the chemical elements present. It is concluded that vitamin A content varied with plant vigor and robustness. The variations in vitamin A content of the plants were likewise associated with the degrees of greenness, and not necessarily with vigor apart from differences in chlorophyll.—Marie Dye and John W. Crist, *J. Nutrition*, 1: 335 (Mar.), 1929.

Manganese in Cereals and Cereal Mill Products—The object of the work reported was to study the variation in the manganese content of cereals of several varieties and of some of their extraction products in relation to ash and protein content. Five varieties of each of the cereals were used as follows: hard winter wheat, soft winter wheat, red spring wheat, white spring wheat, rye, corn, rice, oats, and barley. Similar determinations were made on some of their extraction products. No correlation was found between manganese and the ash content of any of the varieties examined. Neither was there any correlation found between manganese and protein except when the types of wheat were used collectively. In that case, the relation was inverse, the hard winter and the red spring wheats being higher in protein and lower in manganese than the two types of soft wheat.

It is of interest to note that the manganese content of Red Rustproof oats grown in Arlington, at the Experimental Farm of the Department of Agriculture, was found to be several

times higher than that of other varieties of oats studied.

No distinct correlation was established between the manganese content and the protein content of the cereal products, with the exception of the milling products of wheat. The products having a low ash content had a low manganese content, both being due to the low degrees of extraction. A comparison of the manganese content with the diastatic properties of the cereals used in this investigation failed to show any correlation between them. The author further observes that corn and uncoated rice, which are associated with nutritional deficiency diseases, were both low in manganese.—Jehiel Davidson, *Cereal Chem.,* VI: 128 (Mar.), 1929.

The Phosphorus of Grains—It has been shown that the phosphorus content of wheat, oats, and barley is increased as irrigation water is applied. In order to throw some light on whether the increase represents organic or inorganic phosphorus, quantitative determinations have been carried out of the total and inorganic phosphorus. Determinations made on wheat, oats, and barley, in which increasing applications of irrigation water were applied during the growing stage, showed relative increases of total phosphorus. Wheat showed a maximum total phosphorus increase when 35 inches of irrigation water was used. At 67.5 inches, a decrease was observed. Practically all of the increase is in the form of organic phosphorus. Corn showed little increase when irrigation was applied. The increase observed in corn was in the form of inorganic phosphorus. The increase of inorganic phosphorus in corn was shown to be due to the use of varying amounts of farm manure. Samples of grain collected from various sections of the State of Utah, where this work was done, showed a wide variation in the phosphorus content. It was concluded that irrigation, soil, and possibly climatic conditions, all influence the total phosphorus content. It was further concluded that there was no direct relation between the total and inorganic content of the grains studied. The average inorganic phosphorus as compared to total phosphorus in wheat was 6.5 per cent, in oats 9.8 per cent, and in barley 9.6 per cent.—J. E. Greaves and C. T. Hirst, *Cereal Chem.,* 6: 115 (Mar.), 1929.

Chemical Composition of Mustard and Turnip Greens and Losses of Iron in Cooking—Data are presented on the chemical composition, including ash, calcium, phosphorus, and iron, of turnip greens, mustard greens, and spinach, and on the losses of iron in cooking turnip and mustard greens in various ways. The method used for the iron determinations was moist oxidation followed by calorimetric estimation with thiocyanate, the technic including certain modifications of variations in the method reported in the literature. A comparison of the data for turnip and mustard greens with similar data for spinach showed that both vegetables compared favorably with spinach in all respects and were markedly higher in calcium and iron. When cooked in varying quantities of distilled water for 45 minutes, the losses in iron varied from 5 to 25 per cent, depending upon the volume of water used. Tap water (the city supply of Nashville, Tenn.) caused more than twice as great a loss of iron as was caused by an equal volume of distilled water.—A. M. Field, M. T. Peacock, E. Cox, and I. P. Earle, *West. Hosp. & Nurses' Rev.,* 11, 5: 26–28, 1928. Abstr. *Exper. Sta. Rec.,* 60: 190 (Feb.), 1929.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

PHYSICAL DEFECTS

LEROY A. WILKES, M. D., FELLOW A. P. H. A.

Director, Division of Medical Service, American Child Health Association, New York, N. Y.

WHEN is departure from absolutely normal structure or function a real "physical defect," and what are the signs or symptoms by which such defects may be recognized and properly referred to the most helpful professional person for advice and treatment? The answer to this question is not so simple as it might at first appear to be. Physical defects are not merely anatomical variations, but often are intimately related to function, and at times vary in degree with environmental conditions. Physical defects are of two major types:

a. Those which are dynamic in character and produce demonstrable effects in a short time

b. Those which might be regarded as potential "threats" to an individual's health or longevity

Much of the disagreement in professional advice between physicians is centered on these potential "threats" rather than on the dynamic type of defect. Also, a great deal of lost effort, time and money are closely associated with "follow-up" on the part of the nurses to get these "threats" removed or corrected and to persuade reluctant parents to have something done for them, where the parent remains unconvinced of the value of the procedure being recommended. With a limited budget and personnel would it not be more economical and effective to concentrate upon the most urgent defects, merely notifying parents of the others, until the more urgent corrections have been made?

The greatest need in our efforts to restore and promote health, is more *facts* and less opinions on this subject. This necessitates the development of more instruments of precision, which, placed in the hands of easily trained technicians, will furnish data that are objective, reliable and valid. These data must then be handled in an accurate and sound statistical manner and the interpretation of the findings must be made by one who has sufficient background of training and experience, to determine best its real significance and the most effective methods of practical application.

Many records of "defects" today are worthless since many of these records represent only the opinion held at the time of examination, and by the individual examiner.

The opinion of the same examiner, on the same case, is in certain types of defects, such as tonsils, not always constant, and opinions of different examiners on the same case when independently formed, even after examinations made in the same hour, not infrequently differ markedly.

These statements are not intended as caustic criticisms of the examiner's individual ability, but a frank recognition of our present-day limitations. This fact most physicians unhesitatingly recognize. Some less competent au-

thorities still dogmatically declare their ability to differentiate and interpret the signs and symptoms of "abnormality" in many of the border-line cases in which physicians realize their present-day limitations. Anyone can detect extreme cases of defective structure and function, but for such advanced cases little can usually be done; therefore it is desirable to direct our efforts toward preventing defects and toward their early discovery and treatment because:

1. Physical defects tend usually to become worse.
2. Physical defects tend to produce secondary defects.
3. Physical defects tend in time to become irremediable.

What are the more commonly seen physical defects and how may they be detected in order to prevent them from doing the greatest harm to the individual?

Vision and Hearing—Under our modern conditions, especially in our crowded and bustling cities, we find in the younger children defects of vision and hearing. These are not infrequently directly related to disease, such as acute contagious diseases of childhood, local infections, and general infections of the blood and lymph—syphilis and tuberculosis.

Tonsils and Adenoids—Infections of the adenoid tissue of the nose and throat are not always easy to detect in the earliest stages, and there the germs frequently remain latent in the tissues and establish laboratories whose products may sooner or later become absorbed into the blood and insidiously attack other distant parts of the body, at times when resistance is lowered by such agencies as cold, fatigue, undernourishment, and so forth. Not only do the nose and throat offer all the favorable conditions for bacterial growth (warmth, moisture, darkness, and "food"), but the engorgement of the erectile tissue of the nares obstructs breathing; interferes with aeration and purification of the blood; and closes the natural draining passages for the constantly secreted mucus of the pharynx.

This mucus, under such circumstances, is often dammed back into the Eustachian tube and produces abscess of the ear, with impairment of hearing; and also makes possible mastoid infection and meningitis as secondary effects. These complications can in many cases be avoided by early treatment of the original nose or throat infection.

Glandular Enlargements—Enlargement of the glands of the neck may be either a physiological defense against, or the direct result of, disease. This differentiation can only be determined after a careful study of the individual case by a competent physician. The thyroid gland is often enlarged as a result of simple iodine deficiency. The thymus gland, which ceases to function ordinarily in early life, occasionally persists later than usual and causes some difficulty. The lymph glands of the neck filter out poisons elaborated at points of local infection and thereby aid in preventing "blood-poisoning" or general infection. The treatment in such cases is directed to the source of infection rather than to the glands themselves, though the glands may in some cases require attention.

Skin—The skin has many different types of disease which attack it in various individuals. Local conditions often require general treatment as well as local applications and these diseases may be contagious or not. The distinction should be determined early, both for the sake of the patient and of those with whom he may come in contact. Before destroying the characteristic appearance of the lesions, by ill-advised efforts at home treatment, it is advisable to consult the physician early, so that he may see the evidence uncomplicated by such efforts. Time and money are usually saved by this plan.

Teeth—The prevention of dental caries is an urgent problem and one which we have not as yet fully solved. What relation does this condition bear to tooth brushing, diet, mouth acidity, bacterial action, proper mastication, pits and fissures, poor occlusion, heredity, or to mineral deficiency of the blood stream and the many other suggested causes? I feel that we are far from agreed at this time upon this point. It seems quite evident that filling of the cavities retards the process of dental decay, and surely clean teeth do improve one's appearance. It appears to be justifiable to clean the teeth regularly and to have cavities filled by the dentist.

Dental caries has been described by Sir William Osler as "our most prevalent disease," and statistics amply confirm this statement. Further research is greatly needed upon this subject.

Lungs—Lung conditions or diseases are most usually centered about tuberculosis and the pneumonias. These conditions can often be diagnosed early by the physician only after the most careful individual examination with laboratory and X-ray aids. Such examinations require skill and a private, quiet place for the examination.

Heart—Defects and diseases of the heart restrict the activities of the individual in varying degrees. These restrictions can only be determined by careful study and experimentation by the patient and his physician. Each person appears to have his individual circle of permitted activity, even in health, but especially in heart afflictions.

Cardiac cases in school children in many instances are benefitted by special class programs arranged by the teacher and doctor in coöperation. Shorter hours, no stair climbing, avoidance of crowds, and, above all else, frequent reëxaminations and supervision by the doctor are essential.

Bones—Infections of the bones and joints require expert study and diagnosis before treatment can be considered. Efforts not preceded by, and founded upon, a careful medical examination are ill advised.

Orthopedic Cases—There is grave danger in many of the efforts made to conduct "corrective gymnastic" classes where no careful medical examination and treatment outline has been given by an orthopedic physician. Most deformities, such as flat-feet, bowlegs, etc., involve muscle, ligaments, and nerves as well as the bones, and the coördinating mechanism is complicated and not easily understood or appreciated.

Nervous Diseases—Diseases of the nervous system must be carefully distinguished from the emotional lack of control which is so often called "nervousness" and which is seen in the so-called spoiled child, or, as many now refer to it, the unadjusted child. Many of these children appear to respond rapidly to the adjustment of the parent, or of the individual having charge of the child. Emotionally unstable and untrained nurse-maids are at times big factors in these cases.

Cripples—In considering the crippled child we have usually to deal with a combination of defects of the muscular, bony and nervous systems, and in a certain percentage of these cases the mentality is also affected by the underlying causative factor or factors.

The major school problems in cases of crippled children where the mentality is not involved are as follows:

1. The determination as to whether the disease is of a "progressive" nature or is "arrested"
2. The problem of transportation to and from the school
3. The problem of providing the greatest comfort to the child while in the school, in order to conserve his lowered vitality, so he may use it most profitably. (Special furniture is usually required for bad deformities.)

Malnutrition—Here is a much discussed and often abused subject. It is an arbitrary and inclusive term rather than a definite entity and, therefore, must be clearly defined by each one who discusses this subject. Too often the food aspect alone is considered. There are other factors of equal importance to be considered, such as the transportation of the food through the digestive tract and the absorption and assimilation of food, which takes place at various points along the way. Then there is the important function of waste elimination.

All of the bodily processes are affected in varying degree by the emotions and these are far from standardized in different persons. One should study carefully the factors involved and the part played by each. The digestive tube, of which the stomach is but a dilated portion, or storehouse, is composed, to the extent of three-fourths of its bulk, of muscle. This muscle along with other muscle suffers from bodily fatigue or weakness, and cannot in such a state push along the food in the digestive tube at the usual rate to the sites where the specialized digestive functions are located; and so the digestive process is thrown out of gear by the element of fatigue. This factor is an extremely important one in childhood and in adolescence. "Fashion" plays a large part in the adolescent age. Many of the cases of fainting and apparent ennui are due to weakness, which is in turn due to extreme dieting carried on in an ill-advised endeavor to attain the slender figure that, I am happy to be informed, is not to be "the mode" any longer.

Hernia—the escape of the gut through the body wall into a sac of tissues pushed ahead of it—usually occurs at special areas which are inherently weak from the time of birth. Hernia occurs directly as a result of increased intra-abdominal pressure, usually caused by muscular strain induced by heavy lifting or prolonged and strenuous coughing, such as occurs in the paroxysms of whooping cough.

The detection of physical defects in their early stages is distinctly a medical man's problem. There are devices now available, and we hope that more will become available in the near future, which will enable nurses, and others perhaps, to detect suspicious signs early, and send the child at this time to the physician for proper study, diagnosis and treatment. Among such helpful devices we might mention the thermometer, the eye-test charts, the audiometer and other hearing test devices, the scales and measuring devices. These devices and the physician's judgment are at present our final criterion, and will probably remain such, since the up-to-date physician always takes advantage of all improvements in instruments of precision which actually aid in the determination of facts upon which to base his opinion and treatment.

Treatment is wholly a problem within the domain of private and hospital medical practice.

Prevention of physical defects, in so far as our limited knowledge goes, is dependent upon nature and nurture. Healthy living is intimately concerned with:

1. Proper foods with regular elimination of waste
2. "Rest-exercise balance," which, of course, includes sleep
3. Cleanliness of body, mind and soul, which are closely correlated
4. Preservation of body against injury through "safety first" observances
5. Recreation of proper kind and amount for the individual
6. Periodic medical and dental examinations to detect latent "threats" or early involvements before they produce symptoms recognized by the patient
7. Early medical attention to suspicious signs of departure from the normal condition of the individual child—the so-called "droopy

stage," which the mother often detects more readily than the physician, because of her knowledge of the characteristic "normal" appearance and activities of the individual concerned

These suspicious signs include in the earliest stages nothing definitely definable because they are merely the absence of usual characteristic appearance and actions of the individual child. These indications are usually later followed by definite signs and symptoms, such as fever, rash, inflamed or watery eyes, sniffling or mouth breathing as before a cold, discomfort or even pain, diarrhea or constipation, earache, etc.

Of course, chronic eyestrain, squint or frequent headaches at the end of the day, defective hearing, or discharge from the ear, mouth breathing, or frequent sore throat or joint pains, poor nutrition, fatigue from which recovery is not rapid nor complete, shortness of breath, unusual swellings, "limp" or apparent deformity, decayed teeth, skin lesions, all suggest the need of medical attention.

Convalescence from the acute contagious diseases should be adequately prolonged to prevent complications such as those mentioned, and also improvement of heart, kidney, lung, bone, joint and nervous system.

SPECIFIC PREVENTIVE MEASURES

Eyes:

Proper lighting—avoidance of shadows or glare.

Occasional looking at distant objects to relieve the muscular contraction by which accommodation for near objects is obtained. Headaches often result from muscular spasm or "cramps" produced by prolonged close accommodation, particularly where lens defects exist.

Correction of certain visual errors by glasses, when these are suggested by squint, redness or frequent "watering" of the eye, headaches or blurring of the image, and the oculist discovers defects.

Ears:

Ear conditions are commonly secondary to nose and throat troubles, such as nasal obstruction or infections, especially following the acute contagious diseases, commonly involving the accessory sinuses, but may occasionally come independently.

Malnutrition:

Proper quantity and quality of food (selection, combination, preparation, digestion and assimilation).

Correction of interfering physical defects; discovery and elimination of foci of infection; and the avoidance of fads and food cults or doctrines founded upon dangerous half-truths, which are often worse than untruths, and more difficult to combat.

Proper hygienic habits affecting the individual concerned.

Hernia:

Careful medical examination will aid in determining whether the usual sites for hernia are inherently weak in the individual case. Especial care should be exercised, when such conditions exist, to avoid undue physical strains which produce muscular contractions and raise intra-abdominal pressure. Special supports may be worn when indicated to lessen the danger of rupture.

Bony Deformities:

These are sometimes due to faulty diet. In such cases the diet can be corrected before the deformities appear, as in rickets. "Safety-first" is always a good rule to follow, and many needless hazards can be eliminated by protective devices in sports and industry.

Physical defects can be minimized by ordinary care and the practice of the habits of right living. Periodic health examination by a physician is the best safeguard to health.

"Have a Health Examination on your Birthday."

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Purposeful Publicity—Appraisal forms of one kind or another are finding their way into many organizations. Self-analysis is increasing in popularity, and is the "tape measure of utility" these days. The Community Health Association of Boston chose a play as the medium of appraising its own family health work, and presented it to interested audiences as a method of publicity.

The Clark family was one which the Community Health workers had actually visited over a period of more than 2 years. A flimsy excuse brought the nurse on the first occasion, but the so-called unnecessary or unsatisfactory visit led to much greater consequences.

A series of ups and downs in the Clark family motivated the little drama with more than usual success. A new outlook on life, wholesome, nourishing food, and a way to live within their means, brought about an evolution from the border-line of disaster to a position of health and happiness. Just an ordinary family with the usual assets weighed against the usual liabilities—but, by means of wise guidance and thoughtful consideration, the realization of health teaching was grasped, and the Clarks became a "prize family." The play was given for the first time to the senior students of three large schools of nursing in Boston, to show them what good public health nursing is and how satisfactory it really can be, and to enlist their interest in it.

The second audience was composed of board members, theoretically well grounded in the work the nurses are doing in the homes. The play gave them an actual picture of the approach to the home, the kind of service given, and the result of repeated application of health teaching.

The third presentation was for the staff nurses, as a means of stimulating them to have faith in their efforts, by seeing the complete piece of health work of which they are only a part. So often a nurse remains in one locality too short a time to see tangible results of her efforts, or she becomes so lost in the details of the work that she loses sight of the breadth of her own accomplishments.

Twenty Aids to Mental Health for Adults—Go into any book shop these days and you will find arranged on the shelves, on the non-fiction side of the room, numerous volumes dealing with psychology for normal people. Many of these books will be read. Others could be read to advantage, but limited time and inclination are the decisive factors in the selection of reading material for the average individual.

Adults need mental health. Each one of us is vastly interested in his own mental status, but he may be absorbed in the problem from an entirely wrong standpoint, and for this reason may need wise guidance more than a person who is entirely unconscious that there is such a thing as mental health.

Dr. Henry B. Elkind, Director of the Massachusetts Society for Mental Hygiene, has prepared a leaflet, *Twenty Aids to Mental Health for Adults*, which is arresting because of its simplicity and brevity. Each short paragraph is packed with good sound prac-

tical advice—just the things which public health nurses need on so many occasions—and the whole is an appeal to common sense. Copies may be obtained from the Massachusetts Society for Mental Hygiene, 5 Joy Street, Boston, Mass.

The Dairy Counciler—The National Dairy Council, 307 Michigan Avenue, Chicago, Ill., is publishing in 6 issues annually a bulletin known as *The Dairy Counciler*. The first issue appeared in April, 1929.

Judging by the contents, the purpose of the bulletin is to keep organizations posted on the new material offered by the council. Practical suggestions for health programs and general information regarding the National Dairy Council are other features of the first number.

The League Celebrates a Birthday—The League of Red Cross Societies was 10 years old on May 5, 1929. To celebrate this event, a special League Anniversary number of the Red Cross Courier is devoted to the work and achievements of the League during the first decade of its existence.

Red Cross Work for War Veterans—The Red Cross has assumed two definite obligations, one of which is the service to the war-disabled veteran, and the other the preparation for disaster relief.

The magnitude of the former feature of Red Cross endeavor is impressed upon us, when we know that 56,500 cases were handled monthly during the fiscal year, which ended June 30, 1928.

Veterans are aided in the preparation and presentation of claims, and given temporary relief, if necessary, pending the judicial decision of the claim by the government.

A Rise in the Protein Stock Market—In an address before the New York Association of Dietitians, E. F. DuBois expressed the opinion that more attention will be paid to the dangers of partial protein starvation in chronic diseases. Many clinicians are still restricting the protein diet in nearly all patients supposed to have high blood pressure or nephritis, because the excretory organs are considered impaired and should not be overtaxed.

Today, there are instances in certain types of nephritis where good gains have followed a liberal protein intake. When patients have a heightened metabolism, it is easy to deplete the body in respect to protein, if the diet is poor in that foodstuff.—The Control of Protein in the Diet, Current Comment, *J. A. M. A.*, 91, 24: 1897 (Dec. 15), 1928.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

For Expositions and Fairs—Two much used—and still useful—stunts for county fair and exposition exhibits may yet be secured in mimeographed form from the Tuberculosis and Public Health Committee of the State Charities Aid Association, 105 East 22d Street, New York, N. Y. Copies of "Tommy Don't Care and Tommy Docare" or "Health Fortune Teller" will be sent for 10 cents each.

Shall We Pay for Radio Time?—A health officer writes:

I have a limited amount of money for publicity purposes and the question is whether to use it on a bulletin or use radio broadcasting. We have an excellent local radio station which has given us a very low rate for use each day, and I have almost come to the conclusion that this form of publicity would be of greater advantage to the public health work of this community.

One reply to this letter was:

It would be quite unusual for a department or other health agency to pay for radio time. If you pay for radio time the newspapers may well ask you to pay for all space they give you.

So it would seem better to spend your funds —you do not say how much—on a regular bulletin or house organ, or for the preparation of good copy for newspaper use. Either method would promise to cover your city more fully than could be possible by radio. If you issue a bulletin you would issue 6,000 to 8,000 to cover the city.

The two newspapers, with their combined daily circulation of 25,000 and over, would doubtless welcome your copy if it is put up as good as should be the case of radio talks. In connection with the newspapers you would spend your available funds for the part-time of some one to write the copy from material you would supply.

If you use the radio, I wonder if it would be worth while to try for time every day—it depends partly upon the length of each period, the hour, and especially upon your ability to produce material of enough attractiveness in subject and form to lead enough people every day to listen in—poorly done radio talks may do as much harm as good.

Texas Better Health Special—

For several years the Missouri Pacific Railroad has operated health cars in certain sections of Missouri and Arkansas, but the Texas Health Special was an entire train made up of two exhibit cars, two lecture cars, baggage car, diner and Pullman. Besides the train crew there was usually a personnel of 12 or 15 trained physicians, sanitary engineers and technicians. The railroad was invited by Governor Dan Moody and Dr. J. C. Anderson, State Health Officer, to bring the train to Texas. . . .

The first car contained models and exhibits pertaining to general sanitation most needed in the South, particular attention being given to models showing the proper kind of screens for houses, mosquito control work, models of fly-proof toilets, construction of wells, sewage disposal, garbage disposal, rodent control, etc. Then came a lecture car in which public lectures were given by specialists in the different departments of sanitation shown in the exhibits.

The next car was also a lecture car, in which general topics of disease prevention and safety were discussed and illustrated by charts, delineascopes and films. In the fourth car was a model of a complete dairy farm and a milk plant with a miniature pasteurizing plant in operation. . . .

The train traveled more than 2,500 miles and visited 115 towns and cities. Seventy thousand people were shown through the train and listened to the lectures.—

Hygeia, July, 1928.

EDUCATIONAL MATERIAL

"Announcing a New Service for Teachers" is an 8-page booklet concerning speakers, demonstrations, class-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

room helps, plays, and posters supplied by Dairymen's League Coöperative Association, 11 West 42d St., New York, N. Y. *Copy free.*

"First Aid for the Mentally Sick," by New York State Committee on Mental Hygiene, 105 East 22d St., New York, N. Y., describes "the provision made for the emergency care of mental patients"—the "wrong way" as is common in New York State and other states—and the "right way." *Free.*

"Health—Diseases, Drugs and Sanitation," list of United States Government publications now on sale. Revised. Superintendent of Documents, Washington, D. C. *Free.*

"How to Use a Good Refrigerator," by M. E. Pennington. National Association of Ice Industries, 163 West Washington St., Chicago, Ill. *Free.*

"Old Mother Hubbard and Her New Cupboard" contains 50 well written articles on "nutrition with special emphasis on the problem of child feeding." Good paper of a weight to give the pamphlet permanency. The 6-point type is small, but is helped out by the leading and good press work on good paper. Writing above the average, with a number of teasing titles: "Grown-Ups on the Milk Wagon," "He Eats Like a Man," "The Master Clock," "Fit for a King," "The Golden Egg," "Straight as an Arrow," etc. *It has a table of contents.* The articles, one to a page, run about 300 words, and were published weekly by 50 newspapers in Los Angeles County, Calif. Written by Rama V. Bennett, nutritionist of Los Angeles County Public Health Association, and issued jointly by the association and the County Department of Health. *Send 50 cents to the department for a copy.* Should be usable in other counties in other states. Copyrighted but doubtless permission to use would be granted.

"One out of every two workmen cannot see clearly what he is doing," a 5-page press release by L. H. Carris, National Society for the Prevention of Blindness, 370 7th Ave., New York, N. Y. For speakers and house organs. *Free.*

"Tuberculosis: The Maker of Orphans," including "Winning—But Not Won!"—Tuberculosis Society, Racine, Wis. *2 cents.*

The two following are from the Metropolitan Life Insurance Company, *1 Madison Ave., New York, N. Y.*: "Forethought the price of life," a 4-page folder on medical examinations; and "Health, Happiness and Long Life." 22 pages. Elements of health. Limited text.

Both the above have a little too much color and too much ornamental detail to encourage concentration.

The three following are from American Institute of Baking, Chicago (*Free*): "Answering Bread Criticisms," by Roscoe H. Shaw. 8 pp.; "The Bread of Life," by E. V. McCollum. 12 pp.; and "Facts About Bread."

DIPHTHERIA

The Metropolitan Life Insurance Company has prepared a diphtheria car card, a reproduction of the New York State prize winning poster. *Free.*

A 32-sheet billboard reproduction of the prize poster is sold by the State Charities Aid Association, 105 East 22d St., New York, N. Y. *50 cents.*

"What a *Whale* of a difference a little *Health* makes," Health Council, Electric Building, Cleveland, O.—a 4-page, 6″ by 9″ folder with distinctive illustrated cover page. Appeal to "be wise—immunize," and how "Cleveland Fights Diphtheria." *4 cents.*

Tabloids for diphtheria! That's the new prescription in the home city of the Schick test! Pardon the near-tab language, for the Diphtheria Prevention Commission of the New York City Department of Health has gone into tabloids in a big way. It started with

a 4-page tabloid newspaper for Brooklyn which centered around Boy Scout coöperation in the anti-diphtheria campaign. Then Bellevue-Yorkville's *Health News* evolved into true tabloid style which can be appreciated only when seen. Jean Henry is Tab Editor for the Commission, with Marjorie Dent Candee as Bellevue-Yorkville Editor. Harlem (negro) and Bowling Green editions have been issued by the Commission.

In strong contrast with the above is the altogether dignified 9″ by 6″ card for the doctor's office which has been mailed to all practicing physicians in the city.

The card is of heavy beveled board with the lettering in white on a soil-proof brown background and bears in gold the seals of the City and of the County Medical Society. There is space for the doctor's signature.

A device on the back makes it easy to hang on the wall, or to stand on a table or mantelpiece. The wording seems to be successful in providing a card unobjectionable to physicians, and appropriate even for those specialists whose work lies outside of the field of child care.

Four million small folders will be distributed through the mail by the electric and gas companies. An elaborate diphtheria handbook is about to be issued. An illustrated catalog of publications will be supplied upon request to Diphtheria Prevention Commission, Department of Health, New York, N. Y.

HONORABLE MENTION

To Public Health Federation, Cincinnati, O.: for having a full table of contents in *A Survey of Community Dental Facilities,* and for having a brief bibliography in the same report (even though several of the references are too incomplete for ready use).

To the Milbank Memorial Fund, 49 Wall St., New York, N. Y.: in its 1927 annual report—for the effective presentation of professional activities through text, diagrams, tables and illustrations. It is disappointing to note the lack of an index so that, for example, health education must be searched for under such general headings as " Other Activities " or " Special Health Activities." Closer relations between the beautifully produced illustrations and the captions under several of them would be more satisfactory to some readers; and the addition of office addresses to the pages of operating and supervising organizations would be helpful.

To State Charities Aid Association, New York, N. Y.: For " Milestone 55," annual report, with table of contents and other features.

To State Tuberculosis Commission of Connecticut: For a 1926–1928 report using paper for the cover which makes a public document almost attractive; for numerous page half-tones; for partial table of contents.

MOTION PICTURES

The amateur movie clubs, already existing in some high schools and colleges, and many in cities outside of schools, might be enlisted in health scenarios. At least the school audiences would be reached at a moderate expense for materials supplied.

" Speaking the Motion Picture's Language." *The Motion Picture,* 469 Fifth Ave., New York, N. Y. Vol. 4, No. 12. *Free.* Glossary of slang or " technical phrases."

RADIO

" Curtailment of abuses in the radio broadcasting of medical advertising is likely to follow the adoption of a code now under consideration by the National Association of Radio Broadcasters and the Better Business Bureaus, according to a recent editorial in the *Journal of the American Medical As-*

sociation," says *Editor and Publisher,* which calls attention to the need of control and quotes liberally from the *Journal* editorial.

Every weekday the New York City Y. M. C. A. conducts two radio periods, "Health Talk—Gym Class," 9:30 a.m., WOV, 265 M.–1,130 Kc.; and "Health and Happiness Exercises," 11:10 a.m., WGBS, 254 M.–1,180 Kc.

The *Journal of the A. M. A.* announces week by week two groups of broadcasts—at 10:00 a.m. and 8:00 p.m., Central time. Daily except Sunday. Station WBBM, 389.4 M.–770 Kc.

Health agencies having regular broadcasting periods are invited to report hours, stations, etc., for advance announcement.

How about getting local reports on health talks from different stations?

POSTERS

Three of the wood block posters of the Chicago Tuberculosis Institute were included in the Second Annual Exhibition of Chicago Fine Printing. The posters were entered by the Department of Printing Arts of the School of the Art Institute of Chicago.

A poster, 12" by 19", with portrait of "Lillian," who a "few months ago" was not the care-free, happy girl she appears in the picture, is a superior example of the community chest type of poster issued largely for display in factories and offices. The dull-finished India paper with brown ink suggests how some of our drab black and white posters might be improved. Community Fund, 51 West Warren St., Detroit, Mich. *4 cents.*

"Milking Time in Many Lands" is the title of companion posters, 42" by 12". Health Education Department, Dairymen's League Coöperative Association, 11 West 42d St., New York, N. Y. *Each 25 cents.* Each poster includes four panels headed "Peru-Lama," "Arabia-Camel," etc. Vivid colors with simple sketches from which much detail has been eliminated, with good lettering, make them strikingly good to look at and effective for the teacher or mother who wishes to talk about milk. Produced by a silk screen process which avoids the "prettiness" found in many posters. Planned by Louise Franklin Bache, publicity director of the National Probation Association, who is consultant in health education to the Dairymen's League.

"Safety Posters—1929," National Safety Council, 108 East Ohio St., Chicago, Ill. Illustrated catalogue of posters supplied to members. *Free.*

"Tests to Determine if Your Poster Is Effective." *Northwestern Health Journal,* 11 West Summit Ave., St. Paul, Minn., Feb., 1929. *10 cents.* Simple statement of important elements.

"Toy-making Turned to Gay Propaganda," *Survey Graphic,* Mar., 1929, describes and illustrates the group of felt posters produced in Italy for the National Dairy Council, 307 North Michigan Ave., Chicago, Ill., from whom the set may be borrowed. They illustrate a poster form in which some volunteers might become interested. In practice, for effective use, the amount of detail calls for a size two or three times as large as these gay specimens.

TELLING TITLES

"Are You a Dietary Diplomat?"—*Hygeia.* Young America's dietary likes and dislikes.

"Digger of Graves"—Racine, Wis., Board of Health. Press release on "when the spreader of 'colds' becomes socially unpopular, he will cease to be a public menace."

"Don't Be a Transmitter"—*Canadian Red Cross.* About colds.

"Must Mothers Die?"—*News Letter.* Dutchess County Public Health Association.

"What's Happened to the Stork?" *Bellevue-Yorkville Health News.* A paragraph on fewer births in the district.

BOOKS AND REPORTS

Manson's Tropical Diseases. A Manual of the Diseases of Warm Climates—*Edited by Philip H. Manson-Bahr. (9th ed. rev.) New York: Wood,* 1929. 921 pp., 401 figs. Price, $11.00.

A book which has reached its ninth edition has proved its value. In this latest, especial attention has been directed toward the treatment of tropical diseases, which is happily becoming stabilized and effective.

The subject matter has been brought up to date. The illustrations are abundant and excellent, the 23 color plates being especially good.

The work will continue to hold its place as a standard text and reference, and can be unhesitatingly recommended.

The make-up and printing are good.

M. P. RAVENEL

Comparative Neurology. A Manual and Text for the Study of the Nervous System of Vertebrates—*By James W. Papez. New York: Thomas Y. Crowell,* 1929. xxvi + 518 pp., 315 figs. Price, $6.00.

Biologists having to deal with the complex details of the vertebrate nervous system will find in the manual prepared by Professor Papez a very welcome addition to the literature of this highly specialized subject. It is divided into three sections: The first deals with the gross anatomy of the brain of mammals; the second with their microscopic structure; and the third with the nervous system of the lower vertebrates from the reptiles to the fishes. From the standpoint of comparative anatomy and of the logical development of the subject it would have been better to have progressed from the simpler organization found in the lower classes of the vertebrates to that of the more complex mammalian type. The book is founded upon a laboratory course in comparative neurology and is largely descriptive of laboratory and museum material with only occasional references to function until one reaches Chapter 33, on the physiology of the cerebral cortex.

The volume is splendidly illustrated with well executed figures of the complex structures, very fully but uniformly and simply labelled, so that the reader may know at once the nomenclature of the salient features of any of the many illustrations. This feature alone places the book in a unique position among neurological works. A large proportion of the illustrations are new and the range of sources is a wide one. An abbreviated bibliography is given at the end of each chapter. The book is an excellent laboratory manual and a very convenient work of reference.

C. A. KOFOID

Improvised Equipment in the Home Care of the Sick—*By Lyla M. Olson, R.N. Philadelphia: Saunders,* 1928. 109 pp. Price, $1.25.

Miss Olson's little handbook points away from the complexities and extravagances of present-day equipment in the care of the sick in home and hospital. It shows with interesting illustrations and clear explanations that the art of improvising the necessities and comforts of the sick room may be revived. It points out the opportunity that the Nurses' Training Schools have in fitting the student nurses to care for the sick in all walks of life. We are reminded that the large majority of patients with

whom the nurses will come in contact, either as private duty or public health nurses, need and would welcome a return to simplicity in home care of the sick. Every nurse in practice will find the book full of practical suggestions.

HARMINA STOKES

Parents and Children—*By Ernest R. Groves and Gladys Hoagland Groves. Philadelphia: Lippincott,* 1928. 196 pp. Price, $2.00.

This personable third of the Groves' brain children is built along the authors' characteristic style and should be as popular as its predecessors. In a field teeming with daring and unfeeling exploiters, these authors stand out for their sound psychology and their sympathetic and constructive treatment of family relationships.

Until educational institutions pay more attention to that mysterious thing, eugenics, parents will have to depend upon these and other sound authors for their help on family relationships. The sad part of it is that so many parents turn to the bizarre authors who give them more of a thrill for their money—and then they wonder why the magic tricks will not work.

The Groveses do not necessarily furnish a technic of family relationships. I should claim for them that they do give the parent sound basic material. Then let the parent think in terms of his or her own situation.

This particular book is a collection of articles which have appeared in various parental, religious, and educational magazines. The illustrations are of the usual type which appeals to parents—babies, dogs, adults holding young children, etc.—all with intriguing titles, such as "Pals" and "Life's a Joke." Chapter titles include, "Inside Tips for Fathers," "The Emotional Life of the Child," "What to Tell Children About Death," and "The Dangerous Mother." In the Appendix are questions and references which make the book easier for use in child study classes, which are a bit messy unless carefully conducted.

Parental education is in the formative stage and is, for the most part, theory. But in various laboratories, this new and wonderful social contribution is being developed, and since the movement is supported liberally by far seeing benefactors, we may rest assured that better parents are not only a possibility but a certainty. One has only to study the impressive work of such groups as the Institute of Child Welfare Research at Teachers College to see these theories in action with small groups of parents, and then one wishes that a greater number of parents could have such opportunities. But for the present, most parents must depend on the Groveses and other sound and pleasing writers for their meager share of a great benefit. But better times are coming—better times and better and happier families.

HUGH GRANT ROWELL

Healthy Growth. A Study of the Relation between the Mental and Physical Development of Adolescent Boys in a Public Day School —*By Alfred A. Mumford, M.D. New York: Oxford University Press,* 1927. 348 pp. Price, $5.00.

This excellent study attempts to show what relationship exists between mental achievements and physical development. It contains a large number of references to basic scientific studies in physiology and the physiology of exercise, with brief digests of the essentials of such studies.

It attempts to trace the relation between types of physique, and physiological and physical qualities, to mental attainments and school progress. Such factors as electrical resistance of the skin, and oxygen consumption, to mental activity, and of mental activity to physical development are discussed.

Figures on absolute growth of school

boys are given, and there are studies of the relative growth of these boys in such factors as height, weight, chest girth, and vital capacity. The buoyancy index is measured. A study of stamina, its evidences, relation to age periods, and tests for it, is included.

There is also a most interesting chapter on the ailing child, and the relation of health to mental attitudes and to the physiological and physical characteristics.

This is an excellent treatise for educators and physicians who are engaged in work among adolescents. It merits particular study by physical educators and by those responsible for competitive athletic efforts. CHARLES H. KEENE

Bacteriology. A Text-book of Microörganisms—*By Fred Wilbur Tanner. New York: Wiley,* 1928. 548 pp. Price, $4.50.

This book is designed for those entering on the study of microbiology. The author has selected students as his critics rather than those whose experience entitles them to form opinions. If he can be satisfied with this, we wish him happiness.

While there is useful information in the book, much space is given to material the value of which is more than questionable. For example, 60 pages are given to nomenclature and classification of bacteria, though the author recognizes that no satisfactory classification has yet been made. When those who are best fitted to do such work acknowledge the difficulties, and cannot agree among themselves, it hardly seems worth while to burden the minds of beginning students with such discussions.

There are many mistakes which could have been avoided by reference to any standard text, though teachers should always, when possible, consult original sources. As examples: Koch is said to have discovered the anthrax bacillus in 1876, though it was seen in 1849, again in 1850, cultured in 1860, and its etiological relation to the disease shown in 1863; the discovery of the diplococcus of pneumonia is credited to Weichselbaum in 1886, though it was described by Pasteur in France, and Sternberg in the United States in 1880; the discovery of the tubercle bacillus is given as 1884 instead of 1882; the use of anthrax vaccine is said to have "started a method of combating disease," though later in the same paragraph it is shown that the discovery of bacterial vaccines began with chicken cholera.

The English is frequently very poor. Some definitions in the glossary are not only wrong, but absurd.

It is a pity that this book will be used by many whose subsequent training will not correct the misinformation given. We regret that the publishers, whose name has long stood as a synonym for scientific exactness, have put out a book with so many inaccuracies and deficiencies. M. P. RAVENEL

Handbook of Bacteriology—*By Joseph W. Bigger, M.D., Sc.D. (2d ed.) New York: Wood,* 1929. 452 pp. Price, $5.00.

The favorable impression made by the first edition of this book is sustained by the second. It is still a readable and succinct guide for the student.

A few criticisms may be made, most of them concerning omissions rather than errors. The average American would not be willing to make Loeffler's blood serum by the old fashioned method described—2 hours for hardening, and 3 days for sterilization. The autoclave method in which both are done in one operation is used in this country.

The Widal test is described only for serum, and 20 minutes at 37° C. is allowed before examination. The use of dried blood is not mentioned.

The preparation of antigen for the Wassermann reaction omits many of

the safeguards generally employed in this country. We are advised to take a "fresh, healthy human heart" (where can this be had except in Chicago?), grind and extract with absolute alcohol, filter, and to 3 parts add 2 parts of a 1 per cent solution of cholesterin, and 70 parts of saline, giving a "turbid suspension," which is used. Apparently no test of any kind is made. There is no mention of icebox fixation.

The author has apparently never heard of the great improvement made in antianthrax serum in America by the use of spore vaccines, as he states that the most successful is that of Sclavo, made in asses.

The illustrations and printing are good, and for the purposes for which the book is designed, it can be heartily commended. Though printed in Great Britain, it is on excessively heavy paper.

M. P. RAVENEL

Public Health and Hygiene—*By Charles Frederick Bolduan, M.D. Philadelphia: Saunders,* 1929. Price, $2.75.

The author has had a wide experience in public health work, administrative as well as teaching. He has given us a manual for students which covers the ground well, is up-to-date, and in general correct. He is a believer in the historical method of teaching, and begins with a chapter devoted to history. We regret that he continues the fallacy of crediting Morton with the introduction of ether anesthesia, and Warren with having performed the first operation under ether, both being due to Long of Georgia, who removed a tumor under ether anesthesia in 1842, while the operation by Warren was done in 1846. Some other historical inaccuracies are noted, though they are chiefly omissions, probably due to the small size of the book, rather than errors.

The book is well printed, and the colored illustrations are excellent. Most of those in black and white are only fair, and some poor, showing signs of old age.

The book is much better than the average of its type, and can be commended in the field for which the author has designed it.

M. P. RAVENEL

Die Ernährung. Ausstellung für gesunde und zweckmässige Ernährung—*Berlin: Amtlicher Katalog, Verlag Gersbach & Sohn,* 1928. 300 pp. (4 plans.)

This official catalog of the Nutrition Exhibition held at Berlin, May 5 to August 12, 1928, is of interest to workers in hygiene and public health, since it gives a succinct summary of the aims and purposes of each of the several sections of the exhibition and enumerates the displays and exhibits designed to present each subject. It will be useful alike as a plan for public exhibits and as a résumé of current German scientific accomplishment in the field of nutrition. It deals not only with foods and their preparation, protection, and conservation, but also with water supplies and milk.

C. A. KOFOID

Play Day. The Spirit of Sport—*By Ethel Perrin and Grace Turner. New York: American Child Health Association,* 1929. 77 pp. Price, $.35.

Why play days; how play days develop the spirit of sport; the programs of major and minor sports carried out by several city high schools, universities, state teachers colleges, rural schools, and industrial units—all make up the contents of this helpful pamphlet. It is a unique contribution to the director of athletics of an institution or the promoter of civic recreation. The pamphlet is attractive in design, make-up and typography, the text brightened by several excellent photographic illustrations. It is published in coöperation with the Women's Division, National Amateur Athletic Federation.

A. B. TOWSE

Die Malaria in ihrer Bedeutung für die Geschichte Roms und der römischen Campagna—*Eine kulturhistorische Studie von Angelo Celli, Herausgegeben von Anna Celli-Fraentzel, mit einem Geleitwort von Prof. Dr. Henry E. Sigerist. Leipzig: Georg Thieme,* 1929. vi + 118 pp., 1 map. Price, 12 marks.

The author is a celebrated Italian investigator of the malarial parasites of man and a prominent worker in the field of malaria control. His practical work in these problems in the Roman Campagna has peculiarly fitted him to consider the historical aspects of the relations of malaria to the past history of this fever stricken region, so often depopulated and repopulated within historic times. Accordingly he has made an intimate study of available sources, and concludes that from the very beginning of historical records political causes, whether at the hands of Emperors, Goths, or Popes, are not to be charged with the devastations of human life and culture in this area immediately surrounding and tributary to the Eternal City, but rather malaria.

There is historical evidence of a cyclic aspect of recurrent epidemics in which the severity of the disease was marked. There is, however, little evidence of immunity in those who have suffered from attacks of malaria in any of its forms. Much progress has been made in recent years in systematic drainage of the swamps of the Campagna. Quinine in both tablet and liquid form for injection is supplied free by the State, and a staff of 43 physicians is in charge of the campaign. Extensive screening of houses is used as a protection against mosquitoes. Experiments in mosquito control are in progress.

The historical account is supplemented by an extended appendix citing literature covering the prehistoric, classical, medieval and modern periods. This is of great epidemiological value, since the references in historical, political, sociological, as well as medical literature, have been sought out and interpreted by a competent epidemiologist. The treatise is a critical contribution of permanent value to the historical aspect of the epidemiology of this important disease. CHARLES A. KOFOID

The Elements of the Science of Nutrition—*By Graham Lusk, Ph.D., Sc.D. (4th ed. rev.) Philadelphia: Saunders,* 1928. 844 pp. Price, $7.00.

The fourth edition of this book will be welcomed by all students of the science of nutrition as well as by the medical profession. The author has long maintained the premier position in studies on nutrition, and since its first appearance, his work has been a standard reference.

The preface contains one statement which can be commended to all authors, should be printed on a card, and placed on the desk of every would-be author: "Throughout, no statement has been made without endeavoring to examine the evidence on which it is based." Without doubt, this conscientious view has been responsible for the high position Professor Lusk and his writings have always occupied. This latest edition, which has been entirely reset, will, like its predecessors, remain the standard book of reference.

The make-up and printing are excellent. M. P. RAVENEL

Nursing Care of Communicable Diseases—*By Mary Elizabeth Pillsbury. Philadelphia: Lippincott,* 1929. 463 pp. Price, $3.00.

This is a very valuable book, by means of which the hospital and public health nurse may become well acquainted with prophylactic technic. It also contains a concise and well arranged reference to the more recently accepted administrative procedures for

the control of communicable diseases. Frequent reference is made to the Report of the Committee on Standard Regulations for the Control of Communicable Diseases of the American Public Health Association.* It also shows the author's acquaintance with the surveys of health work in large cities made under the direction of the Committee on Administrative Practice.

It is quite natural that when one prepares a book of this character greater emphasis should be placed upon the technic employed in those institutions with which the author has been associated. She therefore lays particular emphasis on certain practices of communicable disease control, within and without the hospital, in Connecticut, especially New Haven, and in Providence and New York City. As the surveys in these cities are admirable examples on which to base and recommend practice, the book makes a very valuable guide for nurses.

A sketchy outline is first given of the causes of disease and the known means for control. Individual immunity and resistance to disease are discussed, as also means of public control. In two well written chapters, the prophylactic technic of nursing is outlined. There follows a chapter on each one of the diseases which are now generally recognized as being reportable.

The book is well illustrated and a great deal of valuable material has been crowded into its 463 pages.

HENRY F. VAUGHAN

* *A. J. P. H.*, Mar., 1927. Reprints obtainable from A. P. H. A. 25 cents.

Living with the Law—*By June Purcell Guild. New York: New Republic,* 1928. 266 pp. Price, $1.00.

This, the 24th in the paper bound, blandly uncut pages, New Republic Dollar Series, is a popular contribution by an obviously "social minded" author to the enlightenment of the laity on the confused and conflicting tenets which comprise what is known as "The Law." Since ignorance of the subject is legally inexcusable, this description and discussion of the law as it applies to persons and social problems ought to be of some value to the befuddled lay (non-legal) body of our citizens. It may even instruct the sanitarian, though neither he nor anyone else will get much out of the chapter on public health, which is the leanest and least satisfactory in the book. On the other hand, the chapters on mental hygiene seem excellent, and those on marriage and divorce, husbands and wives, and parents and children are likewise valuable. Those on aliens and immigration are distinctly less so, but there is a good finish on criminal law and trials. The book is well printed, dispenses with an unnecessary index, and has an inadequate bibliography. It is worth a dollar to those who have to live with the law. JAMES A. TOBEY

Mother and Child. Advice to the Young Wife and Mother of Today —*By Mary Lyon* (*Mrs. Massey Lyon*). *Macmillan,* 1928. 215 pp. Price, $2.00.

This is an ambitious attempt to guide the young mother along a very extensive highway beset with many possibilities. The language and materials suggested are naturally those of England, and similar books for American mothers which appear to me to be more useful in this country are available. In connection with diphtheria, immunization by means of toxin-antitoxin is not even mentioned, though the therapeutic use of antitoxin is recommended. Such small books touching on so many subjects may tend to frighten, instead of inform, young mothers, but perhaps they serve to stimulate a demand for periodic examination and instruction by the physician. If so, they may serve a useful purpose. The print is small, but the subjects are well marked. LEROY A. WILKES.

Community Hygiene—*By Dean Franklin Smiley, A.B., M.D., and Adrian Gordon Gould, Ph.B., M.D. New York: Macmillan,* 1929. 350 pp. Price, $2.00.

This book is presented as a companion volume to "College Textbook of Hygiene" by the same authors. As the title implies, it considers those facts which concern the promotion and protection of public health.

Beginning with a short history of public health work, four sections follow, covering the subjects usually included in a book of this type.

The material is sound, well stated, and sufficiently inclusive. With a few exceptions, the illustrations are only fair. The printing and make-up of the book are good. M. P. RAVENEL

Laws of Pennsylvania Relating to Social Work—*Compiled by John S. Bradway. Philadelphia: Public Charities Association of Pennsylvania,* 1929. 253 pp. + Index. Price, $2.50.

A valuable compilation of the Pennsylvania laws on all phases of social work, with a good chapter on public health and safety. It is indispensable to health authorities and health workers in Pennsylvania, and of interest to sanitarians in other states as an example of a useful and practical compilation of laws on important social subjects.

JAMES A. TOBEY

The Diagnostics and Treatment of Tropical Diseases. A Compendium of Tropical and Other Exotic Diseases—*By E. R. Stitt, M.D., Sc.D., LL.D. (5th ed. rev.) Philadelphia: Blakiston,* 1929. 918 pp. Price, $9.00.

It is noteworthy that two outstanding books on the subject of tropical diseases should have appeared in the early months of 1929. No living man can write more authoritatively on the subject than Rear Admiral Stitt, who, besides being a master of the literature, has had a wide personal experience of which he has made good use.

The present volume contains six new chapters and much new material on topics found in older editions. The author has called to his aid several medical officers of the Navy, who have contributed to a number of subjects.

Approximately one-fourth of the book is given to an appendix, in which matters of great importance are treated. Here one finds an Index of Clinical Diagnosis, designed to suggest quickly diagnostic possibilities. Of especial interest also is the section on Tropical Hygiene. It is well stated that while preventive medicine is of prime importance in temperate climates, it is undoubtedly the first consideration in the tropics.

The book has been brought up to date. The author is well known for his ability to write clearly and to give those facts which the reader needs to know.

The illustrations are good. The general make-up of the book is excellent, though we wish lighter paper had been used. It is easily the best book on the subject which America has produced, and one of the best in any language.

M. P. RAVENEL

Practical Clinical Laboratory Diagnosis—*By Charles C. Bass, M.D., and Foster M. Johns, M.D. (3d ed. rev.) Baltimore: Williams & Wilkins,* 1929. 187 pp. Price, $7.50.

This is practically a new book, entirely rewritten, reillustrated, and brought up to date. It even has a new publisher.

The former editions were favorably received, and were extensively used; so the authors have had the advantage of criticisms and suggestions, which they have made use of in the present volume. They have not burdened the pages with discussions, but have adhered to the

original idea of giving those procedures which have been found the best and simplest. While some may criticise this, it is, in the reviewer's opinion, the most useful plan for the average student as well as laboratory worker.

Except for the colored plates, which are good, the illustrations are not attractive, though they fulfil their purpose. Many of the microphotographs are poor, and might well have been omitted. The material is sound, and given in an understandable fashion. The book will doubtless continue to enjoy its well deserved reputation. M. P. RAVENEL

Handbook of Microscopical Technique. *For Workers in Both Animal and Plant Tissues—Edited by C. E. McClung, Ph.D. New York: Hoeber,* 1929. 495 pp. Price, $8.00.

One undertakes the reviewing of a book of this type, written, as it is, by a number of experts, with considerable trepidation. Since no one is apt to be an expert along all the lines considered, the present reviewer has taken the precaution of getting the opinions of a number of specialists on their particular subjects.

Needless to say, the book contains an abundance of useful material, most of which is well and correctly put. The two outstanding faults are that routine and standard procedures common in most diagnostic and teaching laboratories are neglected for the introduction of those which are unusual and special. The second fault is common to many books of this type, namely, considerable duplication and lack of organization.

The subtitle would limit the book to tissue work; yet considerable space is given to the staining of acid fast organisms, flagella, spores and capsules. In spite of this, one looks in vain for Levaditi's stain for spirochetes or for any method of staining Negri bodies. Neither is even mentioned in the index. A number of other omissions of commonly used and useful methods are noted. Terry's method for rapid diagnosis of tumors is not mentioned, nor is Naylor's technic for staining plant tissues. In a number of places the directions given are incomplete and unscientific. We are told that " higher or lower temperatures " may be necessary for fixing, but the range is not stated, and no mention is made of the rapid method by boiling in 10 per cent formalin. Again we are advised to use pieces of tissue " not larger than a small pea." Why not give more exact measurements according to the metric system? No mention is made of the use of methyl alcohol as a fixative, especially for blood films or smears from exudates. Under the head " Acid Alcohol," page 475, " a 1 per cent solution " is recommended for decolorizing; yet we look in vain to find out what is meant by acid alcohol, and whether the 1 per cent refers to the acid, the alcohol, or to the mixture. Referring to either of the two other pages (321 and 422) on which acid alcohols are mentioned, one finds a number of formulas containing various acids recommended chiefly for fixing tissues. There is no indication of the one referred to as useful for decolorization in a 1 per cent solution.

Some of the procedures recommended are not up to date. For example, in discussing Wright's blood stain, page 245, the method in common use upon the recommendation of Wright himself is not mentioned. Many similar mistakes and omissions could be pointed out, but these will suffice to give a general idea of the shortcomings of the book.

The make-up and printing are in general good, though the paper is heavy and the surface too much glazed. A number of misprints, even of proper names, are noted—occasionally on the same page a proper name will be spelled in two ways. The outstanding feature of the book is Chapter 10, on Stains and Staining. M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

New York State—One of the most complete reports of marriage statistics has recently been published by the New York State Department of Health for the years 1921 to 1924. This report also contains an introductory analysis for the years 1916 to 1924. A detailed table of contents facilitates reference to special summary and rate tables.

In 1927 the Domestic Relations Law was amended, providing for the direct monthly forwarding of the original marriage documents by town or city clerks to the state department and of copies of these documents to the county clerks. This change, according to the Director of Vital Statistics, has brought about a marked improvement in the timeliness and completeness of marriage returns and will make possible the publication of statistics of marriages simultaneously with those of births and deaths.

Los Angeles County, Calif.—The health department report for the year ending June 30, 1928, comprising 385 pages, forms a part of the annual report of all county bureaus. The most notable advances were the completion of the organization plan of new health centers, and the reduction of communicable diseases. During the past 13 years, the infant mortality rate in rural territory has been reduced almost one-third. "In spite of the general ignorance of the Mexicans, our work has reduced their infant mortality from 1 in 3 in 1915, to 1 in 11 in 1927." During the year, nearly 16,000 children between the ages of 1 and 9 years were immunized against diphtheria.

The Pomona health center was open to the public in December. This building, costing approximately $64,000, houses, as do all the major health centers, the division of Outdoor Relief, a small hospital of 6 beds, a number of treatment clinics operated mainly by volunteer assistants of the local medical men, besides the rooms of the local branch of the county health department. The Santa Monica health center, costing approximately $83,000 (including land) was opened in 1928. During the year a large center was planned for Belvedere Gardens, an area occupied by some 120,000 people. This center, containing 22,150 sq. ft. of floor space, is nearing completion at a cost of $83,000, plus $13,000 for the land.

The total population served by the department was 657,555. The expenditures by the county for functions strictly chargeable to public health amounted to 92 cents per capita. Including expenditures by the county recorder for vital statistics, and by school boards for nursing and certain dental activities, the amount was $1.05 per capita.

Child Labor in Mississippi—A report, just from the press, of a study, *Child Labor in Mississippi*, made by the National Child Labor Committee in the fall and winter of 1927–28, reveals no evidence of any deliberate abuse of children. The foreword to the report states:

> It is the same old story; an unconsidering public accepts with but little question low legal standards, and with even less question lack of enforcement. Poor laws are nullified by common consent and there is no fully informed public to decree and enforce by the law of custom what the state and local authorities fail to decree and enforce.

Only those children of 12–16 years of age, who were working regularly and received pay for their work, were included in the study. In the towns selected, the names of all children between 12 and 16

years appearing on the school census were checked against the school attendance records. Those not in school were interviewed at their homes and a record of their work or idleness was made. The children working part time were interviewed at school.

Mississippi, along with 3 other states only, has a 44 hour week for working children. The 8 hour day, and night work provision of the law measure up to the standards generally adopted in other states; but these provisions, fine as they are, are applicable only to children working in mills, canneries, workshops, factories, and manufacturing establishments.

The study of these child laborers, 1,891 in number, shows that 56 per cent were white; 44 per cent, Negroes; 65 per cent, part-time workers, and 34.7 per cent, full-time workers; 33.3 per cent, workers whose jobs were covered by law, and 66.6 per cent, workers whose jobs were not covered by law.

A study of the ages of these working children reveals that 33.3 per cent were 13 years of age or less; 35.7 per cent, 14 and 15 years; and 31 per cent, 16 years or more.

Three-fourths of all the full-time children were working more than 8 hours per day, the average day for all children being 9.6 hours. For 83.1 per cent of the children 13 years or less, 74.7 per cent of those 14 and 15 years, and 71.2 per cent of those 16 years and over, a work day of more than 8 hours was the lot. Of the part-time children 47.1 per cent worked more than 8 hours on Saturday.

Of all the full-time children only 11.5 per cent worked 44 hours or less per week. In considering the age with respect to hours of work per week, it was found that 88.1 per cent of those 13 years or less, 84.5 per cent of those 14 and 15 years, and 96.4 per cent of those 16 years or more, worked more than the legal week of 44 hours. As to part-time children, when the working hours are added to the hours in school, it is shown that more than two-fifths (43.5 per cent) worked more than 44 hours per week.

From the standpoint of the full-time children, night work was of comparatively little importance; but for part-time children, it was of great importance. Nearly two-fifths of the latter were found to be working at night.

Briefly, it may be stated that: (1) Many children are engaged in occupations not covered by the child labor law, for whom there is no restriction as to either age or conditions of work. (2) Many children are engaged in occupations covered by the child labor law at an age which is entirely prohibited. (3) Many of the children who have reached the legal age for such employment are employed in violation of the provisions regarding hours and night work.

Racine, Wis.—The 1928 honor roll of health reports includes Racine, where the health officer in 58 mimeographed pages, bound in attractive light blue covers, has prepared a document worthy of study. This city of 75,000 people has a health department budget in 1929 of $43,870 as compared with $39,895 for the previous year. A birth rate of 19.3, a death rate of 8.9, and an infant mortality rate of 48.7 are recorded. Budget data for 6 years and death rates by principal causes for 5 years are tabulated for comparative purposes.

A feature of the report is a reproduction of attractive posters used by the department in factories and stores. The last 25 pages of the report are devoted to *Appraisal* results on the 1928 schedule of the Committee on Administrative Practice. These results are compared graphically with preceding appraisals. It is noteworthy that the cost of 125 copies of this report was only $69.11, exclusive of the time of the staff.

Reference is made to four educational leaflets published during the year. One of these, "This is no April Fool," was printed in green to correspond in size and shape to the gas and electric bills and was distributed to every house with these bills by courtesy of the Wisconsin Gas and Electric Company. Its title was suggested by the fact that distribution was begun on April first. It set forth the importance of smallpox vaccination and announced the annual campaign of vaccination clinics beginning April 1. During the year, the health officer gave 27 ten minute radio talks on health.

Nursing services, according to a table showing time distribution by services, 1924–28, have increased in all phases except those relating to the supervision of acute communicable diseases. The largest increase in nursing service is in the interest of infants under one year of age. Every nurse delivers to babies in her district a certificate of birth registration incorporated in a baby health booklet, and on the baby's first birthday, delivers a greeting letter including health advice.

Montana—The provision of facilities to investigate spotted fever is outlined in the 1927–28 biennial report. The U. S. Public Health Service has given financial aid to Cascade, Lewis, Clark, and Big Horn Counties to maintain full-time health departments, and has for a number of years been doing investigation work on spotted fever. The last session of the legislature appropriated $60,000 to construct a laboratory in the Bitter Root Valley in order to supply proper quarters for carrying on the work of the U. S. Public Health Service and the State Board of Entomology. This Service has developed a vaccine for the prevention of Rocky Mountain spotted fever, which is furnished free to the doctors of the state on application.

State law places milk control in the hands of the Livestock Sanitary Board. The American Child Health Association, on the request of that board and the State Board of Health, made a milk survey in various towns of the state. It is reported that 2 milk-borne epidemics occurred during the biennium, 1 of scarlet fever and 1 of typhoid, due to carriers handling the milk in dairies.

> The only absolute prevention of such epidemics is proper pasteurization of milk. We do not believe it feasible at the present time to enact and enforce a state law for universal pasteurization, but we do urge cities to pass ordinances requiring the pasteurizing of milk sold in towns where proper inspection of pasteurizing plants can be arranged for.

Maryland—The 1928 report of the Bureau of Sanitary Engineering of the Department of Health opens with the gratifying statement that by far the lowest typhoid fever incidence in the history of the state is recorded for last year. The rate for the state was 5.2 per 100,000, that for Baltimore being 4.2. Ten years ago the rate for the state was 16.9.

The Hagerstown 10 m.g.d. water filtration plant and accessories on the Potomac River were put in service at an approximate cost of $1,250,000. Progress is noted in the development of other water supply and sewage disposal systems. On account of the rapidly increasing popularity of outdoor life, it has become necessary each year to make a complete study of the camps throughout the state with respect to their water supply and sewerage facilities. The activities of one man were devoted to Anne Arundel County, in which the greatest number of camps are located. The value of this work in reducing sporadic typhoid fever has already been apparent. It is interesting to note that one engineer is engaged in field studies of all milk pasteurization plants outside of Baltimore. During the year there were 1,996 field inspections, 205 permits issued, 5,298 samples collected, and over 80,000 miles of travel.

BOOKS RECEIVED

HYGIENE AND PUBLIC HEALTH. (8th ed.) Parkes and Kenwood. Philadelphia: Blakiston, 1929. 823 pp. Price, $7.00.

WHO'S WHO AMONG THE MICROBES. By William H. Park and Anna W. Williams. New York: Century, 1929. 302 pp. Price, $3.00.

A MANUAL OF HELMINTHOLOGY: MEDICAL AND VETERINARY. By H. A. Baylis. New York: Wood, 1929. 303 pp. Price, $10.00.

PROTOZOOLOGY. By John Gordon Thomson and Andrew Robertson. New York: Wood, 1929. 376 pp. Price, $11.00.

THE STRUGGLE FOR HEALTH. By Richard H. Hoffmann. New York: Liveright, 1929. 341 pp. Price, $3.50.

AGELESS YOUTH. By Charlotte C. West. New York: Crowell, 1929. 466 pp. Price, $3.00.

YOUR EYES AND THEIR CARE. By Edgar S. Thomson. New York: Appleton, 1929. 175 pp. Price, $1.50.

FOODS OF THE FOREIGN-BORN. By Bertha M. Wood. Boston: Barrows, 1929. 110 pp. Price, $1.25.

STUDIES IN NUTRITION—INFLUENCE OF SALTPETER. Vol. II. By Ward J. MacNeal. Urbana: University of Illinois Press, 1929. 406 pp. Price, $5.00.

YOU AND THE DOCTOR. By John B. Hawes, 2d. New York: Houghton Mifflin, 1929. 181 pp. Price, $2.00.

ANIMAL PARASITOLOGY. By Robert Hegner, Francis M. Root and Donald L. Augustine. New York: Century, 1929. 731 pp. Price, $6.50.

BACTERIOLOGY OF THE HOME. By Ava L. Johnson. Peoria: Manual Arts Press, 1929. 167 pp. Price, $2.25.

GOOD HEALTH. By Ian S. Thomson. New York: Longmans, 1929. 122 pp. Price, $1.40.

GUIDE FOR A HEALTH PROGRAM. Grades One, Two and Three. By Jessie I. Lummis and Williedell Schawe. Yonkers: World Book Co., 1929. 196 pp. Price, $1.24.

ADVENTURES IN HEALTH. By Nathalie Forbes Moulton. Boston: Little, Brown, 1928. 140 pp. Price, $.70.

EVERYDAY DOINGS IN HEALTHVILLE. A Health Reader. By Emma Serl. New York: Silver, Burdett, 1929. 128 pp. Price, $.68.

PLAY DAYS FOR GIRLS AND WOMEN. By Margaret M. Duncan. New York: Barnes, 1929. 87 pp. Price, $1.60.

RECREATIVE ATHLETICS. (rev. and enl.) Prepared by the Playground and Recreation Association of America. New York: Barnes, 1929. 200 pp. Price, $1.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Tuberculosis Transmission—A bacteriologic study of the dust in patient's rooms may indicate the degree of danger to contacts of the patient. This would seem a rather belabored demonstration of an obvious and not eminently practical measure.

AUGUSTINE, A. E. The Transfer of Tuberculosis by Dust and Other Agents. J. Prev. Med., 3, 2: 121 (Mar.), 1929.

Poliomyelitis Incubation Period—Observations which lead the authors to conclude that the apparent period falls within 6 and 20 days. Experimental infection in monkeys gave an incubation period varying from 4 to 15 days.

AYCOCK, W. L., and LUTHER, E. H. The Incubation Period of Poliomyelitis. J. Prev. Med., 3, 2: 103 (Mar.), 1929.

Health Nursing Education—A survey of educational opportunities in public health nursing leads the author of the paper (which is a chapter from her forthcoming book) to conclude that the outlook in nursing education is promising.

BEARD, M. Education of the Public Health Nurse. Am. J. Nurs., 24, 4: 449 (Apr.), 1929.

Children's Diseases—A detailed statistical analysis of incidence and death rates of the common communicable diseases of children. The maximum incidence among children who have not had a previous attack is six years; the incidence declines thereafter either because of the development of immunity or a less frequent contact. The maximum fatality occurs under one year.

COLLINS, S. D. Age Incidence of the Common Communicable Diseases of Children. Pub. Health Rep., 44, 14: 763 (Apr. 5), 1926.

Typhoid Fever Incidence—A statistical study of typhoid fever in Massachusetts reveals, among other interesting findings, that morbidity and mortality rates increase from towns under 2,500 to towns of 100,000. This suggests that typhoid fever is not a distinctly rural problem, but one of personal contact.

BIGELOW, G. H., and DOERING, C. R. Typhoid Fever in Massachusetts. Am. J. Hyg., 9, 2: 445 (Mar.), 1929.

Herd Immunity—A philosophical discussion of herd immunity to disease, and other phases of public hygiene, which should be made freely available to all health officials, a condition not fulfilled by the present inclusion only in a British health journal.

DUDLEY, S. F. Herds and Individuals. Pub. Health, 42, 7: 219 (Apr.), 1929.

Another Rheumatism Paper—As I have forsworn British papers on rheumatism, I can only report that the author says the paper is about external and internal causes which "contribute to the development of rheumatic disease."

FOX, R. F. Rheumatism in Relation to Industry. J. State Med., 37, 4: 196 (Apr.), 1929.

Poliomyelitis in Great Britain—An epidemiologic and clinical study of a Glasgow outbreak, with the usual findings.

HALLIDAY, J. L. The Glasgow Outbreak of Poliomyelitis in 1928. Med. Off., 41, 15: 155 (Apr. 13), 1929.

Indian Health Work—An outline of modern health conditions among the Indians, the factors which influence

them, and the hygienic measures undertaken; capable men and women are urged to join the service.

GUTHRIE, M. C. The Health of the American Indian. Pub. Health Rep., 44, 16: 945 (Apr. 19), 1929.

Epidemiologic Trends—This paper tells of the danger inherent in extrapolating by prolonging a trend line. Statisticians and epidemiologists wishing to ascertain trends would do well to read more of this paper than the reviewer was willing to do.

HARMON, C. E. A Study of the Problem of Obtaining a Trend Line for Epidemiological Data. J. Prev. Med., 3, 2: 139 (Mar.), 1929.

Epidemic Septic Sore Throat—A detailed epidemiologic report of the milk-borne epidemic of septic sore throat occurring at Lee, Mass., in which 975 cases, with 48 deaths, occurred.

LOMBARD, H. L. Septic Sore Throat in Massachusetts: Epidemiology. J. Prev. Med., 3, 2: 81 (Mar.), 1929.

Pasteurization in Great Britain—What a Scottish veterinarian thinks about pasteurization. One of those "It's all right, but —" articles. An interesting paper for the person who believes in many grades of milk.

MCALLAN, J. The Grading of Milk. J. State Med., 37, 4: 229 (Apr.), 1929.

Irradiation and Colds—A group of cold-susceptible students irradiated for 10 to 16 minutes at weekly intervals had 40 per cent less cold than the controls. This experience controverts a recently published opinion that irradiation had no effect upon colds.

MAUGHAN, G. H., and SMILEY, D. F. Am. J. Hyg., 9, 2: 466 (Mar.), 1929.

Pediatric Progress—Another excellent summary of the advances in pediatric practice during the year. Should prove a useful review for child hygiene workers.

MORSE, J. L. Progress in Pediatrics. New England J. Med., 200, 15: 771 (Apr. 11), 1929.

Nursery Schools—An account of a nursery school conducted on the grounds of a grade school in Chicago. Most interesting.

MURPHY, M. E., and MOHR, E. A Public School Nursery School. Child Health Bull., 5, 2: 38 (Mar. 1), 1929.

Southern Goiter Survey—A statewide survey of endemic goiter in Tennessee indicates that goiter is found more frequently than was supposed to be the case in southern states. Simple goiter is much more common among colored than white children.

OLSEN, R. Endemic Goiter in Tennessee. Pub. Health Rep., 44, 15: 865 (Apr. 12), 1929.

Lead Poisoning—A general review of the administrative measures taken to reduce plumbism, and a consideration of some of the cases still encountered.

OLIVER, THOMAS. Lead Poisoning in Industries. J. State Med., 37, 4: 187 (Apr.), 1929.

Camp Nursing Problems—How the camp nurse is kept busy in the private camp and in the camp operated by a welfare organization is interestingly told. Her opportunities for health education are many and various.

WILLS, G. A., and WEISS, M. M. A. Nursing in Summer Camps. Am. J. Nurs., 24, 4: 388 (Apr.), 1929.

More Septic Sore Throat—A series of papers reviewing the history of milk-borne outbreaks of septic sore throat (White); a clinical study of the cases occurring in the Lee, Mass., epidemic (Holmes); and an invaluable account of the Lee outbreak which summarizes the lessons taught (Bigelow).

WHITE, BENJAMIN, *et al.* Epidemic Septic Sore Throat. New England J. Med., 200, 16: 797 (Apr. 18), 1929.

NEWS FROM THE FIELD

SOCIAL SCIENCE RESEARCH COUNCIL

THE Social Science Research Council has elected the following members under the recently created classification of Members-at-Large: Professor Henry M. Bates, Dean of the Law School, University of Michigan; Dr. Adolph Meyer, Professor of Psychiatry, Director, Henry Phipps Psychiatric Clinic, Johns Hopkins University; Dr. C.-E. A. Winslow, Graduate School Chairman, Professor of Public Health, Yale University; and Professor Robert S. Woodworth, Department of Psychology, Columbia University.

HOSPITAL LIBRARY AND SERVICE BUREAU

ON the approval of the Board of Trustees and Delegates, the American Conference on Hospital Service has made an agreement with the American Hospital Association to maintain and administer the Hospital Library and Service Bureau on and after June 30, 1929.

To give the American Hospital Association full freedom in the administration of the bureau, Donelda R. Hamlin, Director of the Hospital Library and Service Bureau, has sent in her resignation to take effect June 25, 1929.

NEW VENEREAL DISEASE COMMITTEES

TWO new committees are to be formed to replace the Venereal Disease Section of the Associated Out-Patient Clinics Committee of the New York Tuberculosis and Health Association: one on clinics treating gonorrhea, and the other on those treating syphilis.

Dr. Thomas J. Kirwin is chairman of the first and Dr. Dudley D. Stetson chairman of the second.

The committee on syphilis held its

Members of the Los Angeles County Health Department and friends at the opening of the East Side Health Center, Belvedere Gardens—a suburban area near Los Angeles, Calif. The center contains 22,150 sq. ft. of floor space and cost $96,000. It houses the County Health Department, the district emergency hospital, clinics for the indigent sick, and the County Local Welfare Division. An estimated population of 175,000 will be taken care of here. This is the fifth of the new Health and Welfare units to serve the needs of the outlying districts of Los Angeles County.

first meeting on May 3, and plans were laid for an inclusive program and a study of all the clinics in the city caring for venereal diseases. This committee has as its aim the formulation of standards of clinic service and their promotion; promotion of economy and efficiency in the management of clinics; and, in conjunction with the Welfare Council, the coördination of their work, and with allied medical, health and social welfare agencies.

SOCIAL HYGIENE INSTITUTE

THE fourth annual Institute of the American Social Hygiene Association will be held in coöperation with the New York University, the Chautauqua Institution and the Chautauqua Summer Schools at Chautauqua, N. Y. Dr. Thomas W. Galloway will give two courses in social hygiene and Dr. Edith Hale Swift will give a series of lecture-discussions on parenthood and the character training of children. Descriptive leaflets can be obtained from the American Social Hygiene Association, 370 Seventh Ave., New York, N. Y.

DELTA OMEGA LECTURE

THE second annual lecture under the auspices of Delta Omega, the honorary public health society, was delivered at the Massachusetts Institute of Technology on April 12, 1929, by George T. Palmer, Dr.P.H. Dr. Palmer spoke on the school health program of the American Child Health Association, of which he is the Director of Research. Members of the Gamma Chapter at M. I. T. and of the Beta Chapter at the Harvard School of Public Health, as well as many others interested, were present.

Following the lecture, a dinner of the Delta Omega Society was held, with Dr. Palmer and Dr. James A. Tobey, of New York, national secretary of the society, as the principal speakers. Professor S. C. Prescott presided.

WHAT EVERY WOMAN SHOULD DO ABOUT CANCER

THE above is the title of a new publication issued by the American Society for the Control of Cancer. This small pamphlet describes in a brief, succinct manner the main types of cancer and their danger signals, advising medical attention if the latter are apparent. It concludes with a list of practical suggestions regarding ways in which women can help toward the control of cancer, both in their own homes and in society, in general.

DR. KARL IMHOFF VISITS UNITED STATES

DR. Karl Imhoff, the inventor of the famous Imhoff tank, and Mrs. Imhoff arrived in New York the latter part of April on a visit to this country. Their itinerary extended from New York to San Francisco, taking in North Carolina, Georgia, Louisiana and Texas along the southern route, and returning via Chicago, Ill.

PERSONALS

DR. ALLEN HUTCHESON has been appointed City Health Officer of Houston, Tex., succeeding Dr. A. H. Flickwir.

DR. DOUGLAS L. CANNON was unanimously elected by the State Medical Association, April 19, to the State Board of Health to succeed the late Dr. Samuel W. Welch.

DR. ALBERT COMPTON BRODERS, pathologist to the Mayo Clinic, received the honorary degree of doctor of science at the commencement of the Medical College of Virginia, May 28.

American Journal of Public Health
and THE NATION'S HEALTH Vol. XI No. 7

Volume XIX July, 1929 Number 7

Effect of Atmospheric Pollution Upon Incidence of Solar Ultra-Violet Light*

J. H. SHRADER, FELLOW A. P. H. A., MAURICE H. COBLENTZ, AND FERDINAND A. KORFF

Former Director; Chief, Division of Chemical Technology; and Chief, Division of Chemistry

Bureau of Chemistry and Food, Department of Health, Baltimore, Md.

THERE has been much discussion about the rôle of atmospheric pollution in the occlusion of solar ultra-violet light, but a great paucity of experimental work to ascertain the facts. As long as the subject is in the discussion stage, it lacks the stimulus to make it worthy of serious effort on the part of civic bodies to employ remedial measures, particularly when such efforts must overcome the inertia of public opinion as well as the active resistance of financial and commercial interests. It was to find out the facts that this work was undertaken.

In 1922, the International Union of Geodesy and Geophysics, meeting in Rome, Italy, made provision for an international study of the dust content of the atmosphere.[1] Kimball and Hand[2] determined the number of dust particles in the atmosphere of Washington, D. C., and its suburbs, over two winter seasons. The greatest number occurred in December and January, and the smallest in May to October inclusive. In December and January there was over twice as much dust in the city air (Weather Bureau) as there was in that of the suburbs (American University), but in February and March, the difference was only about 33 per cent. They showed that coincident with the decrease in consumption ratio of bituminous coal to anthracite coal, the dustiness decreased. They found about 18

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

per cent less dust at the top of the Washington Monument (500 ft.) than at its base, but more in both cases than at the American University. In Chicago the number of dust particles in the loop district was from 25 to 80 per cent greater than at Chicago University (in a residence section).

In 1927, Bundesen and his coworkers [3] found by spectrographic measurements that there was a materially lower incidence of solar ultra-violet light when the sun's rays traversed the smoke-pall arising from the stockyards than when the wind was from the northeast, which removed it.

It has long been recognized that some method must be adopted for measuring atmospheric pollution, particularly when the objective is to ascertain the rôle of smoke. The general plan has been to weigh and analyze the solid material which settles in catch-cups in stated periods. The results are expressed in terms of tons per square mile per year. This method has yielded very interesting data, particularly as carried out in the extensive investigations of the Committee on Smoke and Noxious Vapors Abatement in England,[4] the Mellon Institute in Pittsburgh,[5] the Herron Company in Cleveland,[6] and Monnett and Hughes at Crafton.[7]

Such data directed public attention to the subject, with the result that municipal ordinances were enacted, and in some cases enforcement facilities were provided, to combat the evil of a smoke laden atmosphere. Among such municipalities was Pittsburgh.

In 1926, a critical study of smoke control in Pittsburgh was made by Meller [8] to ascertain the result of 10 years' enforcement. It was found that whereas the amount of tar (representing smoke solids) was reduced approximately 70 per cent, the total deposit had increased about 40 per cent. Thus one type of pollution was reduced but another substituted, presumably due to the installation of blowers under grates.

If the health aspects of the relation of atmospheric pollution to the incidence of ultra-violet light are to provide the stimulus and constitute the basis respectively for the enactment and the structure of an anti-air-pollution ordinance, we need more definite information as to actual facts. Do suspended solids in the atmosphere actually occlude solar ultra-violet light? If so, are we any better off if we substitute siliceous for tarry solids; in other words, ash for smoke? Such was our problem.

Numerous methods have been proposed for the direct measurement of solar ultra-violet light. Coblentz [9] critically discusses a number of these. Winchester [10] states that determinations based on

the measurement of heat are unsatisfactory. We were forced to use available materials; so chemical methods were adopted, a number being run in parallel.

Our greatest reliance was placed on the lithopone method of Clark,[11] whereby a water paste of lithopone (a mixture of zinc sulphide and barium sulphate) on a microscopic slide under a quartz cover darkens to a reflection factor of 50 per cent in a time period inversely proportional to the intensity of the ultra-violet light. A study of this method by Brickwedde[12] showed that its activity begins with wave-lengths about 254 μμ, and extends to 335 μμ with the maximum at 313 μμ. Variations in the wetness of the paste made no difference in sensitivity. All determinations were made with material from the same batch. Our determinations were always read by the same operator at 11 o'clock in the morning. Within the working conditions of our experiments, the temperature factor was found to be negligible.

The next most useful chemical method was the methylene-blue-acetone-water solution, developed by Webster, Hill and Eidenow,[13] modified by Kimball and Hand.[14] The quartz tubes containing the solution were exposed for 24-hour periods and compared with a standard made up in like manner. Gillam and Morton[15] state that this method is sensitive to the following wave-lengths to the degree specified:

Rays below 275 μμ	88.0 per cent
Rays at 275–325 μμ	6.4 per cent
Rays above 325 μμ	5.6 per cent

Another chemical method run in parallel was uranyl sulphate, used by Anderson and Robinson.[16] Solutions of uranyl sulphate and oxalic acid were exposed for 24 hours in quartz tubes, and titrated with potassium permanganate to measure the photo-chemical decomposition of the oxalic acid. Gillam and Morton (cf. above) give the sensitivity as follows:

Rays below 275 μμ	60.8 per cent
Rays at 275–325 μμ	14.6 per cent
Rays above 325 μμ	24.6 per cent

We also used the so-called potassium iodide test of Pohle.[17] This consisted of exposing a standard solution of purified potassium iodide and dilute sulphuric acid in quartz tubes for 24 hours. The photo-chemical decomposition of the potassium iodide was measured by titrating with sodium thiosulphate.

In order to ascertain the distribution of suspended solids in the atmosphere, catch-cups were placed in three groups: one at the Health

Department, nearly in the center of Baltimore (Group A); five in an arc about 3 miles from the center, thus lying in the near suburbs (Group B); and three in an arc about 10 miles out in the country on farms well back from highways (Group C). Thus, the conditions of the atmosphere as indicated by the findings in Group C constituted our actual control. Any atmospheric pollution or light occlusion in the city which was at variance with the conditions in Group C was incident to city conditions, avoidable or not. In other words, Group C showed us what might be the best atmospheric condition that could be obtained locally. The cups were placed at street level, and protected from animals by locating them at fire engine houses where they could be kept under constant observation.

The determinations of settlings from the atmosphere were made from March, 1926, to October, 1928, but the data in relation to the incidence of solar ultra-violet light of only one year are presented. Some of the earlier lithopone measurements were open to such serious criticism that all readings for the year were discarded. The cups were collected each month and the contents analyzed. Table I gives the data collected from April, 1927, to April, 1928, inclusive, but the tonnage is expressed on a 12-month basis. It is the relative quantities which are significant.

TABLE I

CONTENTS OF CATCH-CUPS EXPRESSED IN TONS PER SQUARE MILE PER YEAR

	Group A	Group B	Group C
Total solids	1,800.0	800.0	340.0
Tar	8.7	5.6	3.2 (2.1)*
Ash	810.0	380.0	130.0
Ultra-violet light **	1.0	—	1.5

* Omitting an inexplicably high value
** Determined by lithopone at one station in Group C

The number of dust particles per c.c. of air was determined by J. J. Bloomfield of the U. S. Public Health Service, using the konimeter.

TABLE II

ATMOSPHERIC DUST DETERMINATIONS* MADE WITH THE KONIMETER

	Dust Count in Particles per c.c. of Air			
	Over 10 μ	Between 5 and 10 μ	Under 5 μ	Visibility during Tests
Group A**	1.0	1	85	Clear, hazy and smoky
Group B	0.6	1	51	Slightly hazy, clear and breezy
Group C	0.5	0	22	Clear

* Each figure is an average of four determinations
** One station

In view of the striking increase in the amount of ultra-violet light indicated in the area where the atmospheric pollution is least, we

checked the dependability of the lithopone method and the technic by a number of the other photo-chemical reactions described, making the determinations at the same time.

TABLE III

COMPARATIVE DETERMINATIONS OF ULTRA-VIOLET LIGHT MADE IN CITY AND COUNTRY

(Average of daily readings from June 16 to August 14)

	Place		Meteorological Control	
			Mean Temp.	Solar and Sky Radiation
Photo-chemical Agent	City	Country	Degrees	gm. cal. per min. per cm.
Lithopone	1	1.40	87–95	370–600
Oxalic Acid	1	1.04	87–95	370–600
Potassium Iodide	1	1.54	87–95	370–600
(Average of daily readings from November 23 to February 10)				
Methylene-Blue-Acetone	1	1.50	63–78	135–225
Lithopone	1	1.98	63–78	135–225

The actual readings are recalculated on the basis of city readings as unity

The readings were taken without any regard for the so-called " clearness " of the day. The term represents such an ill-defined condition that we considered there would probably be as much error in deciding when a day was clear as there would be in the reading itself. In order to ascertain just what difference there might be between readings taken over a long period when all days were used, versus so-called " clear days," the determinations in Table IV were made. These indicate the greater extent to which clear days transmit ultra-violet light than cloudy days.

TABLE IV

COMPARISON OF READINGS ON EACH DAY VERSUS CLEAR DAYS

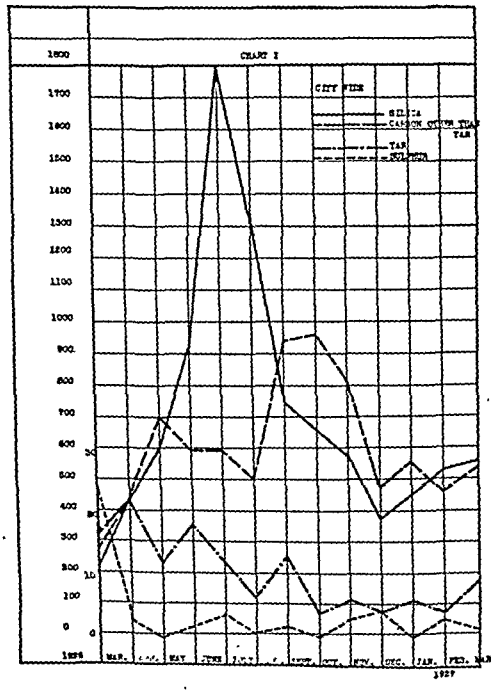
	Clear Days		All Days*	
	City	Country	City	Country
Lithopone				
May–June	1	1.29	1	1.49
Nov.–Jan.	1	1.68	1	1.98
Methylene-Blue-Acetone				
May–June	1	1.42	–	—
Nov.–Feb.	1	2.00	1	1.50

* These readings are taken from Table III

From the above data it is clear that there is a far greater incidence of ultra-violet light in the country than in the city, and there is far more atmospheric pollution in the city than in the country. Carrying the inquiry further in order to ascertain whether these facts are really related, we measured the amount of atmospheric pollution and the incidence of ultra-violet light on the top of a city building 230 feet high, and coetaneously on the sidewalk near its base. The results are given in Table V.

These data show clearly that in the city there is an inverse relation

TABLE V



MEASUREMENTS OF DUST AND ULTRA-VIOLET LIGHT AT DIFFERENT HEIGHTS IN CITY

Dust	On Top of Building (T)	On Sidewalk (S)	Ratio (T : S)
Solids (Tons per sq. mile)	4,566	5,359	1 : 1.18
Tar (Tons per sq. mile)	22	53	1 : 2.41

	0.39	0.26	
	0.54	0.39	1 : 0.7
Methylene-Blue-Acetone*	16.8	15.6	
	17.2	16.2	
	14.2	15.0	1 : 0.97

* Each figure is an average of twenty-five daily determinations

between atmospheric dirt and the incidence of ultra-violet light. It is quite presumable that atmospheric dirt is the cause of the occlusion of much solar ultra-violet light. To settle this point, we determined to measure the occluding effect of various dusts. We constructed a wooden box 36" by 18" by 18", with an inlet for introducing the dust, and with quartz windows 5½" by 5½" at opposite ends. Two small electric fans were placed inside to keep the dust in suspension.

The incidence of solar ultra-violet light was measured in the beam traversing both quartz windows, thus passing through the box, and again when the given dust was introduced. These results are recorded in Table VI.

In Chart I, we have presented curves showing how the constituents of atmospheric pollution vary over the season. During 1926 unusually large amounts of bituminous coal were used, followed by an increasing use of anthracite. Manufactured gas is being used to an increasing extent for heating. The spring of 1926 was unusually dry. The curves show that the greatest pollution from all sources occurs in the spring and summer seasons, and the peaks of the different kinds of pollution lie at different seasons.

Determinations of the incidence of bacteria in the air were

TABLE VI

RELATIVE INCIDENCE OF ULTRA-VIOLET LIGHT THROUGH SEVERAL DUSTS

	Percentage of transmission		
	1 gm. dust	2 gms. dust	5 gms. dust
Fuller's earth*	77 per cent	75 per cent	60 per cent
Street sweepings*	94 per cent	64 per cent	54 per cent
Lamp Black*	40 per cent	21 per cent	14 per cent

* Sieved through 200 mesh

made by exposing agar plates for approximately 5 minutes, incubating at 37° C. and counting the colonies. The peak of bacterial contamination lies at the time of year when the incidence of ultra-violet light is least.

Some measurements were made to determine the sky radiation in the city. Determinations were made with lithopone of direct solar and diffuse skyshine on 14 " clear " days in October and November, 1927. The results are tabulated in Table VII.

TABLE VII

DETERMINATION OF SKYSHINE VERSUS DIRECT SUNSHINE

	Sun	Sky
14 determinations	0.13– 0.33	0.13– 0.25
Average	0.284	0.199

Thus, the skyshine constitutes 70 per cent of the direct solar ultra-violet light, a good confirmation of the figure reported by Tisdall and Brown[18] in Toronto of about 50–67 per cent.

SUMMARY AND CONCLUSIONS

Solar ultra-violet light has been measured by the lithopone method and checked by three other chemical methods. Dust-cups and konimeter measurements of atmospheric pollution indicated that this was heaviest in the center of the city and fell off to approximately one-sixth as much in the country. Contrariwise, the amount of ultra-violet light in the country was 50 per cent greater than in the city. In parallel with this, it was found that the amount of settled dust on the top of a tall city building was materially less than at street level, while the incidence of solar ultra-violet light on the building was greater than at street level. Measurements made on " clear " days showed somewhat greater incidence of ultra-violet light than on cloudy days. The passage of ultra-violet light through confined air artificially polluted with fuller's earth, street sweepings and lamp black, respectively, shows that they are increasingly effective in the order mentioned in occluding solar ultra-violet light. Skyshine yields about 70 per cent of the amount of ultra-violet light received by direct sunlight.

From this study, we conclude that:

1. The lithopone method is dependable for field use in measuring solar ultra-violet light.

2. The belief that atmospheric pollution actually occludes ultra-violet light to a very great extent is well founded.

3. The constituents of atmospheric pollution in summer are greater in quantity and different from those in winter.

4. Skyshine is equivalent to about 70 per cent direct sunshine in content of ultra-violet light.

5. Carbon as tarry products is materially more inhibitive to the incidence of ultra-violet light than siliceous materials.

Public Health and the Public Purse[1]

TO have their good deeds interred with their bones is the common lot of sanitary reformers: an unmindful public gives little heed to disasters which would have been. The achievements in diminished mortality in fevers in a period of 70 years following the initiation of sanitary legislation in England in 1848 were summarized by Sir William Hunter. He pointed out that if the rate of mortality which existed in England and Wales for the years 1847–1850 were applied to the 4 years 1916–1919, the following would be the position:

Typhus would have killed 100,000, whereas the actual number of deaths was 7.
Typhoid would have killed 70,000, whereas the actual number of deaths was 3,626.
Cholera would have killed 114,000, instead of which there were no deaths from cholera for 30 years.
Smallpox would have killed 42,000, whereas the actual number of deaths was 110.
Scarlet fever would have killed 122,000, whereas the actual number of deaths was 5,390.
Diphtheria would have killed 30,000, whereas the actual number of deaths was 19,631.
Measles would have killed 56,000, whereas the actual number of deaths was 29,272.
Whooping cough would have killed 66,000, whereas the actual number of deaths was 23,087.

Medical and Public Health Work in a Large Coal Company*

DANIEL J. KINDEL, M. D.

Medical Director, The Consolidation Coal Company, Inc., Fairmount, W. Va.

THIS paper is a brief report of the work of our organization as it has been carried on for the past year or more by The Consolidation Coal Company, Inc., one of the largest producers of bituminous coal in the United States.

For a number of years physicians have been employed on a contract basis. Each employee contributed a stated amount monthly toward his medical expenses, which was withheld from his wages and paid to a designated physician. Obstetrical, surgical, and venereal disease cases were charged for in addition, and a wide variety of such fees existed. The physicians were chosen by mine superintendents, other officials, or by the people themselves. One physician usually served several communities of the same company and frequently those of other companies. He would necessarily sublet some of his work. This had its undesirable features.

Slightly more than a year ago there were approximately 35 physicians employed by our company on this basis, each independent of the others, without coördination and coöperation. No definite plan of work existed; methods and equipment were not standardized; and a great deal of the practice of medicine was on a pill dispensing basis. Records were inadequate, and an organized health program was lacking.

Nurses administered to the sick and injured in the homes; assisted with the household duties; and filled in wherever they were needed.

Many of the physicians and nurses deserve great praise for their work, as at times it was very rigorous and pioneering. Transportation facilities were very poor and inadequate, living conditions bad, and many unreasonable demands were made. With improved highways, living conditions, state and county health programs, educational work, and a direct interest on the part of the companies, there is a gradual transition to a new mode.

---

* Read before the Industrial Hygiene Section of The American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

FUNDAMENTAL FACTORS OF OUR MEDICAL PROGRAM

Our main problem is to provide medical and nursing service for 10,000 employees and their families. Our operations extend into 4 states—Kentucky, West Virginia, Pennsylvania and Maryland—with 6 divisions, the minimum distance between any 2 being approximately 60, and the maximum 300 or more miles. One division covers 30 miles and our communities are widely separated.

The scattered locations of our employees and communities make it difficult at times to carry on our program, as we cannot centralize our medical and nursing work. This has resulted in the establishment of areas or " medical units," based upon location and number of employees, each in charge of a physician and a public health nurse. Usually there is one full-time physician to a unit but in several instances two are required. At present there are 13 units, in the charge of 18 full-time physicians. Employees receive all usual medical attention, including minor surgery. Hospital service is given by private or state institutions, with the exception of one division where we operate our own 50-bed hospital.

Employees contribute on a monthly basis, and no charge is made for treatment, drugs, dressing or other materials, but $20.00 is allowed the physician in obstetrical cases, and small fees in venereal diseases.

The executives of the company, realizing the possibilities of an organized medical department, made a survey of the medical, hospital, nursing and sanitation problems of all its properties in 1926 and the early part of 1927. The present program had its inception about July 1, 1927.

Staff and Personnel—Our personnel consists of 18 full-time physicians in charge of 13 medical units, a chief hospital surgeon, an assistant, a full-time laboratory physician, 6 dentists, a supervisor of public health nurses, 11 full-time public health nurses, and 8 hospital nurses. During the past year we have reduced our staff of physicians from approximately 35 to 18, replacing part-time by full-time men. Under the direction of the supervisor, the public health nurses are conducting a well rounded-out public health program, with the assistance of the physicians and other personnel.

The medical director is directly responsible for the activities of the doctors, nurses, hospital, etc., to the director of industrial relations who in turn is responsible to the vice-president of operations.

The Medical Program—The most important major phase consists in the care of injured and ill employees and their families. This includes visits to the home, and consultations and treatment in the medical unit. One of our greatest problems is to make patients come to

the doctor's office. Rather than go to the unit, the physician is often called to the home for very minor ailments, which is time consuming and annoying.

This is the only objection to the plan of monthly contributions by the employee, for some feel that the monthly sum they are paying entitles them to call the physician to the home for any cause.

We believe that a long established precedent in the coal field is responsible for this and are gradually overcoming it by an educational campaign through the doctors, nurses, personnel managers, operating officials and by group meetings between departments and staffs.

We have standardized equipment, instruments, drugs, and supplies, so that all units are practically the same, and we have attempted to impress our employees with the necessity and advisability of seeking relief here whenever possible, since they can be better taken care of where the facilities are available than in the home. Progress is slow, but there is a gradual improvement.

Dispensing of Drugs is the second major phase. Company employees attended by company physicians are provided with drugs, medicines, dressings and supplies without additional charge. A stock of the usual drugs and biologicals is kept at each medical unit, but patients may be requested to pay part or all of the actual cost of a special drug. A standardized drug list was determined on and each physician now requisitions his supply from this every 2 months. As a result considerable economies have been effected.

Clinics—At the clinics conducted by the company nurses, more than 7,000 individuals, mostly children, were examined by physicians and dentists during the first 8 months of 1928. This is a small beginning but represents progress.

Immunizations—While a number of immunizations have been given during the past 8 months, this activity is still in its inception, and for the present will be confined to localities where the prevalence of disease justifies it.

There were 9,947 immunizations against typhoid fever. Approximately 9,500, or 95 per cent of several communities, were immunized through compulsion, because typhoid fever was prevalent in 1927 (45 cases with 3 deaths). Only 2 cases have been reported in 1928, 1 in a person from another locality, and 1 who had not been immunized. There were 5,376 smallpox vaccinations and 1,885 toxin-antitoxin immunizations.

Daily Medical Reports—Each physician is required to make a daily medical report which covers the cases seen each day. This was primarily intended as a record of the prevalence and character of dis-

ease in our communities, with age, color and sex of those affected. A diagnosis is made if possible; otherwise the patient's chief complaint is given. A record is kept of new and return cases and of those injured in their work. This report is available to the nurse for selection of special cases. The physician indicates those he wishes her to attend. These reports are checked and summarized monthly. Persons consult our physicians for headaches, colds, constipation and other minor ailments since fees are not charged. In this way many ailments are seen which would otherwise escape attention. Only a beginning has been made, but we believe that we are making the first controlled morbidity study of an entire industrial population, numbering between 40,000 and 50,000, of all ages, nationalities and both sexes.

TABLE I

QUANTITATIVE SUMMARY OF DAILY MEDICAL REPORTS OF THE CONSOLIDATION COAL COMPANY, INC., 1928 COVERING A 5-MONTHS PERIOD

Total Calls	52,046
House Calls	14,277
Office Calls	37,378
House and Office Calls	391
Colored	6,787
White	45,259
Males	29,092
Females	22,954
Average Calls per Day	24.96
Number of Physicians Reporting	16

Table I is a summary of 5 months' work. Our employees are receiving $2.00 worth of service for every dollar paid in. The average cost per family for the usual medical attention, excluding hospitals, is approximately $36.00 per year, for which they actually pay $18.00.

Compensation Injuries—Another phase of our medical program is the care and treatment of compensable injuries, which require 1,100 to 1,300 services per month, approximately one-fourth being first treatments.

We have recently instituted the "Return-to-Work" certificate, which an employee must receive before he may return to work after an accident or long illness. The purpose is to decrease absenteeism, avoid risk, regulate compensation, and obtain data as to time lost due to injury.

Another phase of our medical program is the employment of dentists. At present we have agreements with 6 dentists, under which the company provides the location and makes collections over the pay rolls for services in accordance with a standard list of charges. The dentist agrees to adhere to these fees, extract all deciduous teeth free of charge, and perform all ordinary maintenance work for children

under 15 years of age at half price. Each child is to receive a dental examination at least once during the school year. A record is kept and follow-up work is done.

Most tonsillectomies are done by our company physicians, and a charge of $20.00 is made. Each individual is required to pay all or part of this fee, as determined by a committee, consisting of the public health nurse, the personnel manager, the mine superintendent and the auditor. If the report of the committee justifies free operation, no fee is charged.

Other special clinics, such as eye refractions and orthopedic corrections, are conducted in a similar manner, except that specialists are called in and the amount a patient cannot pay is either taken from a company charity fund or provided for by state and county funds, or such organizations as the Rotary Club, Kiwanis and similar organizations.

It is part of the duties of the physician and nurse to keep a check upon the sanitary conditions of the communities in which they work, reporting those which are a menace to health to the proper authority for correction.

Housing and Civic Improvement Department—The company has a well organized department of housing and civic improvement which has direct supervision over buildings, grounds, sanitation, etc., and cooperates with the staff of the medical department in the establishment of proper sanitary conditions.

This department maintains regular garbage and refuse collections, disinfects houses, sees to the construction and cleaning of vaults and excreta disposal, maintains the water and sewerage systems, and the cleanliness of the communities.

Laboratory—A clinical, pathological and bacteriological laboratory has recently been established, intended to serve all divisions for water and milk analyses. Physicians of our company, as well as others, may send specimens for examination, a charge being made to non-company doctors.

The Nursing Program—Our public health nursing program is divided into 10 heads:

1. Bedside
2. Prenatal
3. Maternity
4. Infant Welfare
5. Child Welfare (preschool)
6. School
7. Tuberculosis
8. Communicable Disease
9. Social Service
10. Educational

These titles indicate the type of work included in the 10 divisions. In the 8 months under consideration, 16,398 services have been ren-

dered, to which might justly be added correction of defects, attendance on clinics, weighing of children, etc., which were the direct outcome of instructions given by nurses in the course of their work.

CONCLUSION

We have given you a summary of the work of this company, and in conclusion wish to state that we have attempted to organize our medical and public health program on a sound and workable basis, one which possesses elasticity to meet our needs and also one from which we believe the employees and the company as a whole will derive the most benefit.

Sick Insurance for Airplane Workers

COMPULSORY insurance against sickness is established in Italy by a law of January 10, 1929, for persons employed on all non-military vessels and airships. The insured persons are entitled to free medical and surgical aid, including hospital care, and to a cash benefit equal to 60 per cent of their wages. The insured women are also entitled in case of confinement to obstetrical aid and to a cash benefit payable for 12 weeks, and longer if they are unable to resume their work; the wives of insured men are given obstetrical treatment. Free medical aid is also given to the members of the insured person's family.

In case of the insured person's death his wife or children are paid an amount equal to 1 month's wages. The funds necessary for the administration of this law are to be derived from contributions by the employers and the workers.—*Gazzetta Ufficiale,* Rome, Feb. 8, 1929, p. 619.

Strength and Weaknesses of County Health Organization*

MILFORD E. BARNES, M. D., DR. P. H.

Director, Ohio Training Station for Health Officers, Greenville, O.

THE executive head of any department of health carries grave responsibility. It is his duty to safeguard the health of the people under his jurisdiction. The field has expanded materially during the last half century, and it is probable that it will continue to expand.

The problems of preventive medicine have been simplified so far as knowledge goes, but administration is more complex. The practice of public health requires detailed knowledge of preventive medicine, and also familiarity with matters entirely alien to the medical curriculum. The modern practitioner of public health must specialize.

Public health work is vitally concerned with individuals, in so far as they may affect the health of the general public. The control of disease involves invasion of the home and privacy of individuals, which is diametrically opposed to the traditional spirit of the American people. A typhoid fever outbreak may involve the search for carriers, and the restriction of their occupation. Effective milk control, and the provisions of the Shepherd-Towner act require intimate acquaintance with the private affairs of individuals. In one state, the health officer is not only authorized, but directed, to make an examination of any person who has, or is reasonably suspected of having, venereal disease. Such a provision involves intrusion into private affairs to the utmost degree.

We must remember that official health agencies derive their financial support from public funds. The broad general principle that funds for local developments should be collected locally applies to health work as well as to other projects. It is unfair to use state taxes for the benefit of selected counties; to tax a county for the benefit of one or more of its cities; or the rural population for the benefit of the incorporated towns. Public health work, if it is to be supported from public funds, must be developed on a basis which,

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

so far as possible, will benefit equally *all* of the people taxed. This carries the corollary that public interest must be developed in the proposed work. Without it local taxes cannot be assessed or collected.

The complexity of modern health work, the need for specially trained personnel, for intimate contact with the people, the obligation to give service for the equal benefit of those concerned, and the necessity for developing local interest to support tax levies—all indicate that the ultimate unit of health organization must be local, if it is to be adequate and enduring. The unit of operation must be large enough to provide funds sufficient to employ trained personnel, and to support the work conducted under its direction. It must be small enough to allow the establishment of friendly relationships with the people of the community, equal distribution of services, and the development of local interest.

Except in the case of very small states, these considerations would reduce the size of the field units to the county, city, township, or town. Cities of sufficient size can, and often do, support their own health departments. In operation, however, no city department can confine its interests to the corporation limits; for example, in milk control, meat inspection, sewage disposal, and water supplies, unless the outlying districts are under adequate health service. The township and small town are generally too small to support the work required of a modern health department.

The county, on the other hand, offers such advantages that in many states it has been chosen as the base for local health administration. It is timely to consider the strength and the weaknesses inherent in this plan of organization.

ELEMENTS OF STRENGTH

1. The county is the largest unit of purely local government. Other activities based upon this unit have long been recognized and accepted—there are county commissioners, financial officers, courts and officers of justice, superintendents of schools, and agricultural agents. It would therefore involve no radical departure if there should be a county department of health, but put such work on a par with other important agencies.

2. Being a legally defined governmental unit, the county is a unit for taxation purposes, with an established system for collecting and handling tax funds and apportioning assessments. The collection of a special assessment for health work, or the allocation of funds offers no special difficulties.

Although counties vary markedly in wealth, as a rule sufficient funds for the maintenance of a full-time health department can be raised without undue burden upon the taxpayer. The expenditures for health in the county with which the writer is connected amounted in 1927 to $18,107.35, or 43 cents per capita, which maintained a full-time staff of 8 members. The budget for 1928 totals $21,950.00, or approximately 51 cents per capita, including all subsidies. In the first 7 months of 1928, 17,509 services were rendered. These included the handling of 995 cases of reportable disease, 4,993 sanitary inspections, and 11,063 services by the public health nursing division, among which were 3,755 home calls, including 140 prenatal, 100 maternity, 708 infant welfare, 387 child welfare, 320 tuberculosis or tuberculosis contacts, 172 orthopedic, and 255 calls upon physicians in behalf of patients. The year's services will approximate 30,000.

This type of record can be duplicated in dozens of counties, and is cited as a concrete example of what can be done on a very reasonable per capita levy. In several of the southern states effective work is conducted on a much smaller budget, through the employment of units of smaller size. The extent of the work will necessarily be limited by the money available; but effective work is usually possible under a budget within the financial ability of the average county.

3. The average county is of a convenient size for one unit of staff to handle. Personal contacts can be established which permit even those activities which involve intrusion into private affairs. A fairly equal distribution of services is possible over an entire county, both urban and rural. In the county referred to, one-third of the home calls were made among the rural inhabitants, who comprise 62 per cent of the population, and probably one-half of the services have been directly for their benefit. Under no other system can rural districts share to such an extent in the benefits of organized health work.

4. The county system is advantageous over smaller areas in the handling of such matters as control of communicable disease, disposal of sewage, development of pure water and milk supplies, and prevention of stream pollution—all of which extend beyond legal boundaries.

5. Finally, as the county is a local area so far as government is concerned, popular interest in health work can be developed and capitalized, and coördination of county-wide private agencies interested in limited phases of health activities secured.

INHERENT ELEMENTS OF WEAKNESS

1. Vulnerability to political influence, which it shares with every other agency supported by public funds. The sinister influence of

politics is felt in every activity which involves important interests. Securing of sewage disposal plants, safeguarding of milk supplies, and food inspection, frequently involve financial loss to individuals; so there is almost sure to be a certain amount of opposition to such measures. It takes courage to work for measures designed for the public good in the face of opposition. Many a health officer is held back by the fear that his whole program will be jeopardized if he carries out his duties fully.

Specific instances can be cited illustrative of this point. A city passes regulations establishing certain minimum requirements as to milk, then proceeds to ignore them. An influential establishment maintains a malodorous plant which arouses bitter criticism on the part of neighboring citizens; yet for 10 years nothing is done to abate the nuisance. A judge or a lawyer owns houses and refuses to make sewer connections. A city pours its untreated sewage into a small creek in spite of the protests of riparian landowners. Many specious reasons can be advanced in extenuation of such conditions; but the real reason lies in politics. Boards of health do not feel that it is expedient to take the action which all admit is indicated. In numerous counties this sinister influence extends even to the appointment of members of the staff. Many health officers are handicapped by employees whose dismissal they are powerless to effect, because the storm which would follow, being localized, is likely to be violent.

Happily, with the increasing employment of well trained workers, the public is coming to appreciate the fact that health work is above politics, and, as between the advocate of special privilege and the conscientious health officer, its best interests lie in backing the department of health.

2. There are differences in practices prevailing among county health organizations. In the county system, the principle of decentralization is followed, and responsibility is placed upon the county officers, who carry out their programs according to their knowledge and ability, as affected by local conditions.

It is obvious that a health officer who is a political timeserver has little interest in any activity which jeopardizes his position, and that the untrained man will work less effectively than the trained. The result is great disparity in the effectiveness and nature of the work attempted. The solution will be expedited by greater supervision on the part of state departments of health.

However, the same disparity obtains as between state and city departments of health. One has but to scan the pages of *Municipal Health Practice for the Year 1923*,[1] based upon a study of 100 of the

largest cities in the United States, to see the chaotic condition which prevails in health practices. For example, scarlet fever has long been classified as a communicable disease. If isolation of cases is justifiable, it must be based upon scientific observations. Presumably such observations as to duration of transmissibility are valid regardless of location. Why, then, do isolation periods vary from 21 to 35 days, depending upon the residence of the patient? The absurdity of this situation is illustrated along the Ohio-Indiana boundary where families living on opposite sides of the same road have been placarded for periods of 30 and 21 days, respectively. It cannot be maintained that the boundary line has any influence upon the duration of the infective state.

Surely the time has come when health measures which are basically sound can be made more nearly uniform. Interstate agreements, and greater supervision over the county health services will be necessary to bring this about.

3. The county is too small for the proper handling of numerous important problems. If there were uniformity of practice among the counties, this would not be so serious. A county health officer found a case of typhoid fever on a dairy farm and he promptly stopped the sale of the milk in his own county; but the producer shipped it into the adjoining county. Several days later this came to the notice of the officer of the second county, who had to make a trip of 30 miles beyond his borders to protect his county. The probability is that the producer shipped into a third area, with no one the wiser. One county refuses a permit for the production of milk for sale in the county because of the bad state of the barn and the uncleanly manner in which the milk is handled. This is of no effect if, as at present, the producer can ship into a city with even more stringent regulations but not enforced. In the control of epidemics, and safeguarding of water supplies, the county is too small a unit, and state action appears to be absolutely necessary.

4. Being a local organization, it shares in the effects of intertown rivalry, in any antipathy between the rural and urban populations, in the outcry against increased taxation, in the vociferous opposition of individuals who develop personal dislikes toward members of the staff, in the whispering campaigns which abound in every small community. The only solution is the conscientious discharge of duty, exercise of patience and tact, constant effort to develop a public conscience as to public health, and the saving grace of humor.

In conclusion it may be pointed out that the strength inherent in county health organization far outweighs the weaknesses. There are

some counties too large for any single unit to handle satisfactorily, and others too small or too poor to permit the raising of the required funds. In some the roads make it impossible to distribute the services with any degree of uniformity. It is evident that such counties will require special adaptations to meet their several conditions. In the vast majority of the counties in this country, however, it would appear that adequate health work is possible of realization based primarily upon local support.

SUMMARY

1. Health work must be organized on a local basis to be adequate and enduring.
2. The elements of strength inherent in county health organization are:

   The county is the largest unit of local government; and offers precedents for such organization.
   It is a taxation unit, of sufficient resources to insure adequate funds.
   It is of a convenient size for one unit to handle.
   It offers advantages over smaller units in the handling of various health problems.
   It permits the development and capitalization of local interest in health work.
3. The weaknesses are:

   Vulnerability to political interference.
   Divergence of health practices.
   Being too small an area for handling certain important health problems.
   As a local organization, it is subject to strictures arising from provincialism.

NOTE: The studies and observations on which this paper is based were conducted with the support and under the auspices of the International Health Division of the Rockefeller Foundation.

Carriers

THE New York State Department of Health has reported the discovery in 1928 in the upper part of the state, of 23 typhoid carriers—a total of 167 known, exclusive of those in state institutions. Forty-eight cases of typhoid fever were traced to these newly discovered carriers, who ranged in age from 15 to 68. Female carriers predominated, approximately 4 to 1. In all but 1 case, there was a history of a previous attack of typhoid fever. In 1, 37 years had elapsed, indicating the persistence of the carrier state over a long period. In 7, gall bladder operations were done with complete success, as indicated by laboratory examinations. These were released from restrictions.

Stability of Commercial Sterilizers in the Presence of Milk

G. N. QUAM AND SIDNEY N. QUAM

Long Island University, Brooklyn, N. Y.; and Sugar Creek Creamery Co., Danville, Ill.

DUE to the increasing popularity of chemical sterilizers, much has been written concerning the uses of the hypochlorite and organic chlorine containing preparations. Those containing sodium hypochlorite seem to be most favored by the dairy and bottling industries. The so-called sodium hypochlorite sterilizers have neither the same composition nor the same degree of activity or stability. It is well known among chemists that the addition of sodium hydroxide to a sodium hypochlorite solution increases its stability to a marked degree. Some of the sodium hypochlorites on the market owe their stability to the high sodium hydroxide content; a notable example being antiformin.[1] One of the authors[2] observed that the stability of dilute solutions of sodium hypochlorite in the presence of metals could be greatly increased by the addition of less than 1 per cent of sodium hydroxide, tri-sodium phosphate or calcium hydroxide. The great stability of some of the commercial products is no doubt due to the addition of such compounds in excess during the manufacturing process, for their cleansing action, or to increase the chlorine capacity. R. L. Wells[3] found that the deterioration of the strong hypochlorite solution at room temperature varied greatly with the difference in composition, and that various salts may act as retarders or accelerators.

The stability of the sterilizer under plant conditions has received some attention. Levine, Toulouse, Peterson and Buchanan[4] found that a standard hypochlorite solution in distilled water suffered practically no loss, while with the addition of 1 per cent corn sugar there was a drop of about 67 per cent in the available chlorine in 1 hour at 79° F. Cane sugar was far less destructive.

In a study of the action of rubber on a commercial hypochlorite one of the authors[5] found that in 8 hours the hypochlorite suffered a 95.38 per cent loss of available chlorine, while in a so-called alkaline sodium hypochlorite a loss of but 80.4 per cent was noted.

Unlike the hypochlorites, the organic chlorine containing sterilizers, such as chloramine-T, are unusually stable. Leach[6] found that all the American made chloramine-T, dichloramine-T and other prep-

arations, were very stable, and their activity was greatly lessened by the slight increase of alkalinity.

The fact that in the dairy industry, sterilizers may come in contact with milk and milk products during their legitimate use seemed to warrant a systematic study of the effect of whole milk on the stability of commercial sterilizers.

REPORT OF EXPERIMENTS

The commercial sterilizers used are indicated by the numbers I, II, III and IV. I is a liquid sodium hypochlorite preparation, strongly alkaline with sodium hydroxide; II a liquid sodium hypochlorite; III a crystalline tri-sodium phosphate sodium hypochlorite preparation; and IV a chloramine-T preparation. Each sterilizer was diluted to a concentration equivalent to approximately 200 p.p.m. available chlorine.

For a series of determinations at a given temperature 500 c.c. portions were placed in sterile flasks partially immersed in a constant temperature bath; 1 c.c. of whole milk was added to each; and at definite time intervals determinations of the available chlorine were made. The loss in available chlorine was calculated in terms of p.p.m. and recorded as in Table I.

The stability of IV was so great that data for it are given only at 109.4°, 123.8° and 145° F. In all cases, IV was unusually stable;

TABLE I

STABILITY OF STERILIZERS IN THE PRESENCE OF MILK AT DIFFERENT TEMPERATURES. LOSS EXPRESSED IN PARTS PER MILLION (P.P.M.) OF AVAILABLE CHLORINE. 1 C.C. MILK ADDED TO EACH 500 C.C. STERILIZER

		Loss in Available Chlorine		
Temperature	Sterilizer	½ hr. p.p.m.	1 hr. p.p.m.	1½ hr. p.p.m.
73.4° F.	I	31.2	40.8	50.7
	II	45.3	56.4	64.8
	III	45.3	56.4	66.2
91.4° F.	I	56.4	70.5	90.2
	II	64.8	81.7	93.0
	III	65.0	79.0	93.0
109.4° F.	I	68.0	100.1	—
	II	90.0	110.0	—
	III	95.1	111.0	—
	IV	15.5	16.9	—
123.8° F.	I	88.8	131.4	—
	II	112.0	132.0	—
	III	122.0	141.0	—
	IV	16.9	17.9	—
145° F.	I	152.0	183.3	186.0
	II	148.4	169.2	180.8
	III	161.4	183.2	184.7
	IV	30.3	35.2	39.4

though a decrease in stability with rise in temperature and extended exposure was noticeable. For each sterilizer a definite, uniform decrease in stability with increase of time for any given temperature was noticed. As the temperature increased the rate of deterioration was accelerated. The rate of deterioration was found to be specific for each sterilizer. The order of increasing rate of deterioration of the three sodium hypochlorite sterilizers was found to be I, II, III.

From observations within the range of temperatures studied, it appears that the change in rate of deterioration due to increase of temperature is progressive. The importance of maintaining relatively low temperatures during the sterilization of dairy plant equipment seems obvious.

The above data emphasize the fact that sodium hypochlorite sterilizers may vary greatly in stability and activity. The user cannot be too strongly urged to consider carefully the conditions under which the sterilizer is to be used, as well as the properties of the various commercial products.

Publicity for Public Health

THE Illinois State Medical Society has upheld the action of the Chicago Medical Society in expelling Dr. Louis E. Schmidt. The charges on which this expulsion was based are " unethical advertising." It is reported that the action of both the Executive Council and the house of delegates of the state society was unanimous in its decision.

Dr. Schmidt had appealed from the action of the local medical society on the ground that it was not justified in holding him responsible for the advertising of the Chicago Public Health Institute, and furthermore that there was nothing unethical in the advertising of that organization.

It is expected that Dr. Schmidt will make a further appeal to the Judicial Council of the American Medical Association which will have to rule on the issue of whether it is ethical for the medical profession to advertise as a public health measure.

Rating Your Milk Supply

LEONARD V. PHELPS

Bacteriologist, Health Department, Bluefield, W. Va.

WITH the ever increasing use of the Standard Milk Ordinance of the U. S. Public Health Service, a corresponding increase has been made in the application of its scoring system to the milk supply of various communities.

The federal system divides the milk supply of the community into three parts for scoring purposes:

A. Retail raw milk
B. Raw milk to plants
C. Pasteurized milk

To each is given a total of 500 points, so distributed as to cover every phase of production, handling, etc., according to the importance of each phase. The division score is obtained by enumerating the number of points actually earned out of the total possible 500, and from that determining the percentage of the 500 points that this represents. Such a procedure gives the three division scores which are essential for the determination of the general rating of the milk supply.

The problem now is to give a general score or a general rating, as it will hereafter be referred to, which will show on the basis of the three divisional scores to what degree the community has been successful in properly producing and properly pasteurizing its milk supply.

Herein lies the reason for this article—because it is the opinion of the writer that a formula now in use by the U. S. Public Health Service does not show what it is intended to show, and in some instances gives a false picture as to the correctness of production and the degree of perfection of pasteurization of the milk supply.

The U. S. Public Health Service formula is as follows:

$$GR = \frac{C \times A\% + D \times B\% + E \times B\%}{2}$$

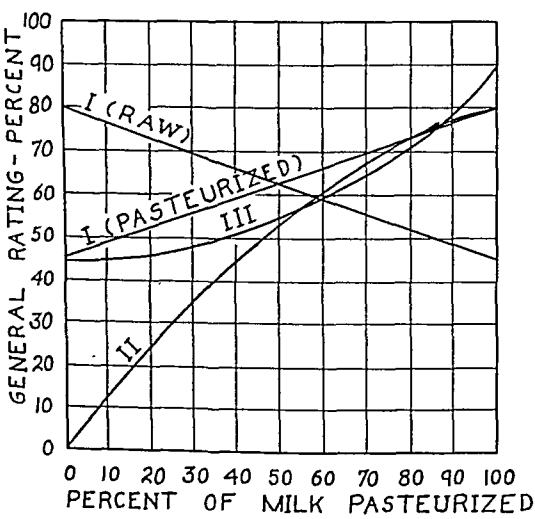
where:
A = Gallons retail raw milk sold per day.
B = Gallons pasteurized milk sold per day.
C = Retail raw milk rating.
D = Raw milk to plant rating.
E = Pasteurization process rating.
GR = General rating.

The U. S. Public Health Service has issued a statement along with this formula stating that, " A 100 per cent general rating means that all of the community's milk supply has been both properly produced and properly pasteurized."

This statement is true when the general rating is 100 per cent, but it can easily be shown that for values less than 100 per cent the general rating, hereafter referred to as the G. R., is often misleading. The G. R. could only have a value of 100 per cent if there were no retail raw milk sold, and the raw to plant, and the plant process scores were both 100 per cent. This would make it practically an impossibility for a community to get a G. R. of 100 per cent. When only a fraction of the milk supply has been pasteurized, the smaller the fraction, the less is the accuracy of the G. R. Most community milk supplies have a very low G. R., usually less than 50 per cent.

The G. R. can be increased or decreased as much as 35 per cent, when the A–B–C score is 90–80–80, simply by increasing or decreasing the percentage of the milk pasteurized, without regard to the methods of production or pasteurization. Obviously, such a G. R. is useless as far as it shows the grade of production and pasteurization.

CHART I



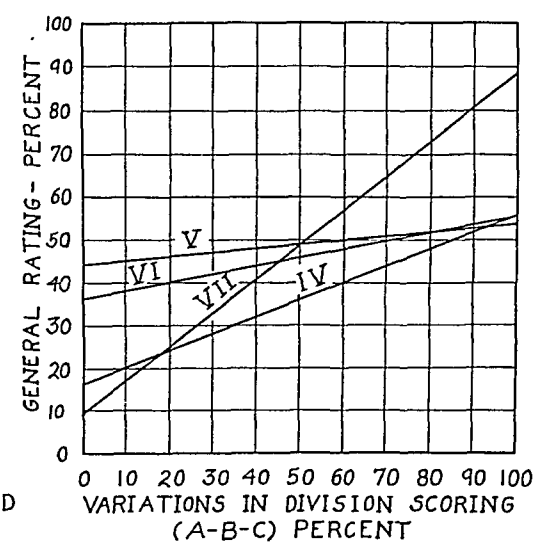


CHART II

I. Variation in per cent raw with constant A–B–C Score
I. Variation in per cent pasteurized with constant A–B–C Score
II. Variation in per cent pasteurized with A varying in the A–B–C Score
III. Variation in per cent pasteurized with B varying in the A–B–C Score
IV. Constant per cent pasteurized with A varying in the A–B–C Score
V. Constant per cent pasteurized with B varying in the A–B–C Score
VI. Constant per cent pasteurized (20 per cent) with B and C varying in the A–B–C Score
VII. Constant per cent pasteurized (80 per cent) with B and C varying in the A–B–C Score

Curve I (pasteurized), Chart I, shows the straight-line graph of increase in the G. R. when the percentage of milk pasteurized is regularly increased up to 100 per cent, and when the three division scores are 90–80–80. Hereafter the three division scores will be referred to as the A–B–C score. This curve shows an increase in the G. R. of 35 per cent. Curve I (raw) shows the opposite effect gained by increasing the percentage of raw milk in the community. It will be noticed that the G. R. regularly decreases as the percentage of raw milk increases up to 100 per cent.

In referring to the A–B–C score:

A = Retail raw milk score.
B = Raw to plant score.
C = Plant process score.

In all curves referred to hereafter the letters A, B and C are used as representing the A–B–C score apart from any system of notation used by the U. S. Public Health Service. An A–B–C score of 90–80–80 is used as representative of a very good score.

TABLE I

A–B–C Scoring	Per cent Pasteurized	Per cent Raw	General Rating
90–80–80	0.1	99.9	45.0
90–80–80	10.0	90.0	48.5
90–80–80	20.0	80.0	52.0
90–80–80	30.0	70.0	55.5
90–80–80	40.0	60.0	59.0
90–80–80	50.0	50.0	62.5
90–80–80	60.0	40.0	66.0
90–80–80	70.0	30.0	69.5
90–80–80	80.0	20.0	73.0
90–80–80	90.0	10.0	76.5
90–80–80	99.9	0.1	80.0

The general rating when the per cent of milk pasteurized is varied, the A–B–C score remaining constant.

Curves II through VII are of interest as showing something of the properties of the different quantities used in the U. S. Public Health Service formula for determining the G. R. They show that values of A are relatively unimportant compared to values of B and C, as far as their effect in increasing the G. R. is concerned, and that the chief factor in increasing the G. R. is the actual percentage of milk pasteurized in the community.

One can take an A–B–C score of 40–20–80 with the percentage of milk pasteurized as 20 per cent, and receive a G. R. of 26 per cent. Then simply by reducing the values of A and B one-half, giving an A–B–C score of 20–10–80, one can, by increasing the percentage of milk pasteurized 60 per cent, receive a G. R. of 38 per cent. In other words, it is possible in this instance to produce the community's milk supply only half as properly and yet receive a G. R. 12 per cent

TABLE II

A–B–C Scoring	Per cent Pasteurized	Per cent Raw	General Rating
40–20–80	20	80	26.0
20–10–80	80	20	38.0
80–60–80	20	80	46.0
40–30–80	80	20	48.0

This table shows that a milk supply having a production score (A–B) 50 per cent lower than another may receive a higher general rating simply by increasing the per cent of the milk supply pasteurized.

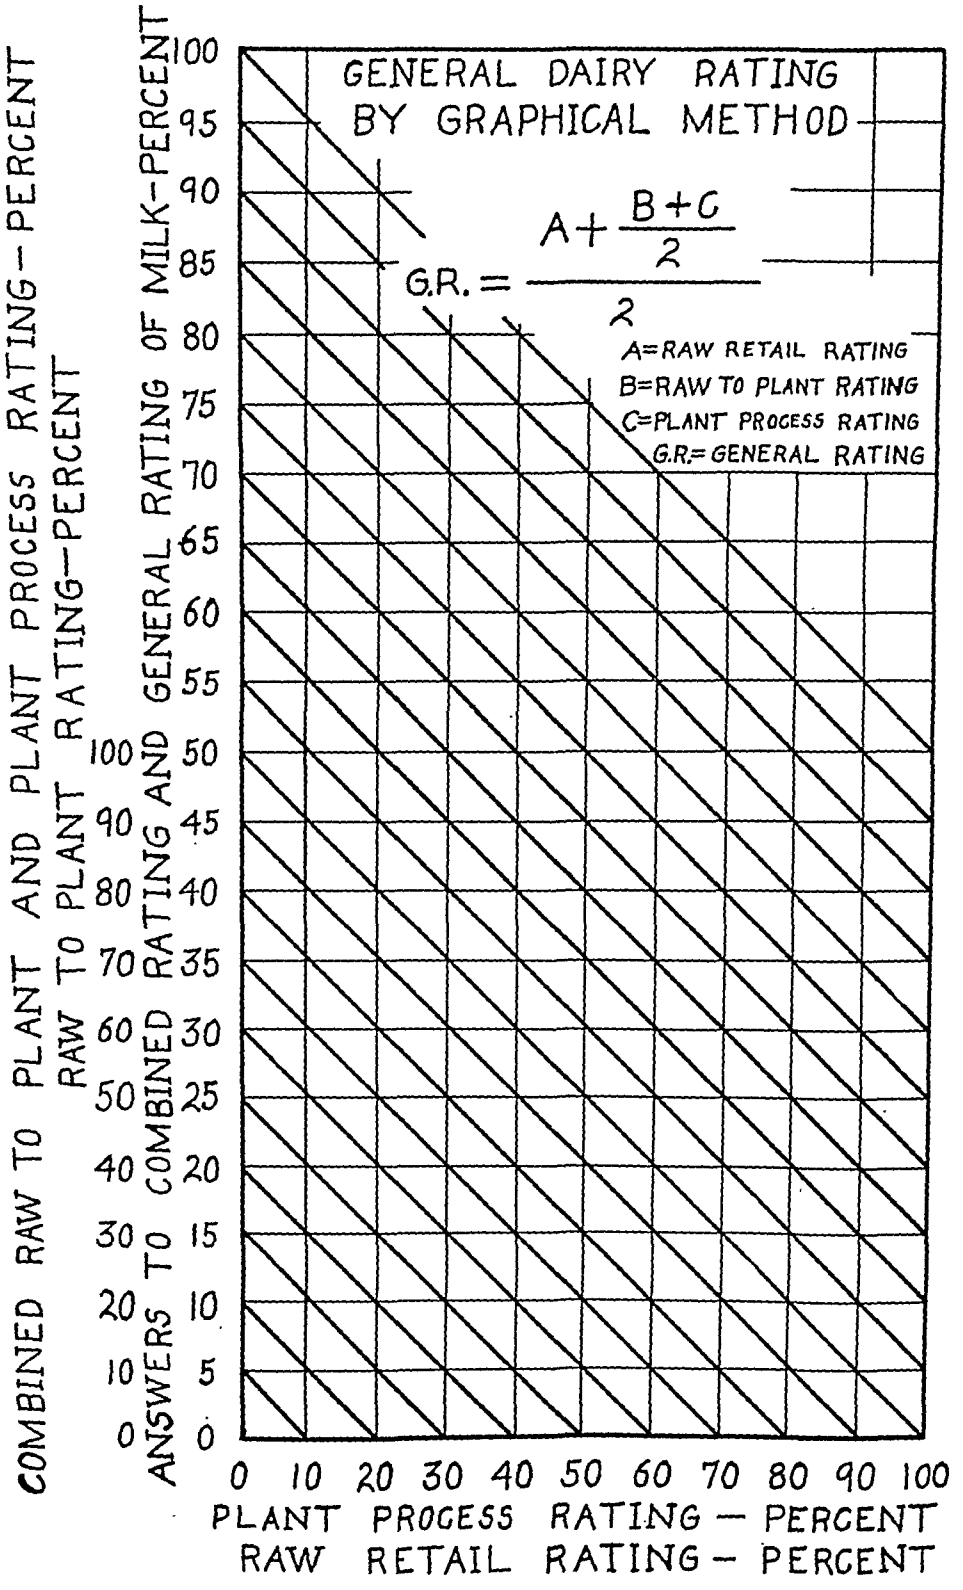
higher than before. Obviously a formula that will give such misleading values for G. R. is useless.

The second reason for this article is the suggestion of the use of another formula for determining the G. R.

Since the three A–B–C division scores were not affected by the amount of milk being pasteurized in the community, why is it necessary or logical to permit the G. R., which is a resultant of all three, to be affected by the percentage of milk pasteurized? If some other relationship were desired, it would be all right to consider the amount of milk being pasteurized, or any other value, for that matter; but we are interested in a general rating.

The G. R. is based on the A–B–C score. A 100 per cent G. R. should mean that all of the community's milk supply has been properly produced and that, if any of the milk is pasteurized, the process has been correct.

The objection might be raised at this time, and legitimately, to the use of the term " General Rating " in describing the result obtained by applying the U. S. Public Health Service formula to the community's milk supply. If the term is used, it should be qualified by some word showing it is really not a general rating but a " special rating," wherein pasteurization is stressed.



Two things are wanted by the dairy executive—the degree of compliance with the regulations as stated in the Standard Milk Ordinance, and the numerical figure showing how much of the community's milk is pasteurized. The G. R. should show the degree of compliance with the dairy regulations and only that. G. R. of 100 per cent should mean that 100 per cent of the regulations had been complied with.

TABLE III

City	Federal General Rating	General Rating New Method
A	53.1	70.7
B	50.5	72.5
C	45.7	73.7

This table shows that three cities, scored in 1928 by the U. S. Public Health Service rating formula, can be reversed in order of highest score by applying the new formula. This gives a truer picture of compliance with dairy regulations.

CHART III

GENERAL DAIRY RATING
BY GRAPHICAL METHOD
G.R. = A + (B+C)/2 / 2
A=RAW RETAIL RATING
B=RAW TO PLANT RATING
C=PLANT PROCESS RATING
G.R.=GENERAL RATING
COMBINED RAW TO PLANT AND PLANT PROCESS RATING—PERCENT
RAW TO PLANT RATING—PERCENT
ANSWERS TO COMBINED RATING AND GENERAL RATING OF MILK—PERCENT
0 10 20 30 40 50 60 70 80 90 100
PLANT PROCESS RATING — PERCENT
RAW RETAIL RATING — PERCENT

The following formula is suggested as one which will show the degree of compliance, one which will give a true, and not misleading, G. R.

$$GR = \frac{A + \frac{B + C}{2}}{2}$$

where: A = Raw to retail rating.
B = Raw to plant rating.
C = Plant process rating.
$\frac{B + C}{2}$ = Combined rating.
GR = General rating.

Three cities received a G. R. following an inspection by a federal officer. By applying the new formula, in which the percentage of milk being pasteurized has no effect, it was found necessary to reverse completely the order of cities (Table III) according to their G. R.

The third reason for this article is the suggestion of the use of a graphical chart for the solution of problems, given the A–B–C scores, to determine the G. R. The use of the chart will, where much statistical or comparative work is done, eliminate the tiresome arithmetical work. The directions for using Chart III are as follows:

TO DETERMINE COMBINED (RAW TO PLANT AND PLANT PROCESS) RATING

A. Read up left hand edge of chart and find line corresponding to raw to plant rating, which is outside line of figures.

B. Read across bottom edge of chart and find line corresponding to plant process rating.

C. Put a pinpoint where these two lines meet.

D. If it is on a diagonal line, the figure at the end of the line will indicate the combined rating, namely one-half of B plus C.

E. If the pinpoint is between diagonals, its distance from the diagonal line will indicate the fraction.

Example: Raw to plant rating ..... 61 per cent
Plant process rating ..... 53 per cent

The pinpoint comes between diagonal lines 55 per cent and 60 per cent. Answer is 57 per cent combined rating.

TO DETERMINE GENERAL RATING

A. Read up left hand edge of chart and find line corresponding to combined rating, which is outside line of figures.

B. Read across bottom edge of chart and find line corresponding to raw retail rating.

C. Put a pinpoint where these two lines meet.

D. If it is on a diagonal line, the figure at the end of the line will indicate the

general rating, namely one-half of the sum of the combined rating added to the retail raw rating.

E. If the pinpoint is between diagonals, its distance from the diagonal line will indicate the fraction.

Example: Combined rating ..... 57 per cent
Raw retail rating ..... 83 per cent

The pinpoint comes on diagonal line 70 per cent. Answer, general dairy rating is 70 per cent.

CONCLUSIONS

1. The federal general rating formula is too inaccurate and misleading to justify a continuance of its use.

2. A general rating should be based on the following only, without regard to the percentage of milk pasteurized:

Retail raw score
Raw to plant score
Plant process score

3. A general rating should show the degree with which the community complies with the regulations in the Standard Milk Ordinance.

RECOMMENDATIONS

1. That the use of the federal formula be discontinued.

2. That if the federal formula is retained, the resulting general rating shall be labelled something other than general rating, in order that it may be distinguished from a true general rating.

3. That a formula be used for determining the general rating which shall not involve the use of the percentage of milk being pasteurized.

4. That a formula shall be used that will show the degree to which the community complies with the regulations of the Standard Milk Ordinance.

NOTE: The writer wishes it distinctly understood that this article is in no sense an attack, personal or otherwise, on the U. S. Public Health Service.

Antituberculosis Vaccination in Italy

THE National Children's Bureau of Italy plans to introduce in 10 large cities optional antituberculosis vaccination of new-born infants.

According to the plan, the registrar of vital statistics in each city will report the births every day to the pediatric clinic of that city. The clinic will then send to the family a circular, with a reply card attached, explaining in simple language the reasons in favor of antituberculosis vaccination in cases where the child was exposed to contagion. If the parents agree, the child is given the vaccine. From that time on the child will be under the supervision of the clinic as long as this is considered necessary for its health.

The purpose of the work is to reduce the incidence of tuberculosis among infants and to ascertain more about the nature of the vaccine.

Sterilization of Milk Bottles in Soaker Type Washers*

LEWIS SHERE AND GERALD L. HOEFT

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

THE proper cleansing and sterilization † of milk bottles is receiving increased consideration by health authorities and is important in building up public confidence in the safety and healthfulness of milk as a food. Cleanliness and a reasonable degree of sterility of all equipment with which milk comes in contact is a prime requisite.

A tabulation of published reports of diseases traced to milk and milk products, by Armstrong and Parran,[1] shows 45 instances where infection of milk bottles has been reported as the factor causing the outbreak.

The Department of Health of Chicago in its supervision and control of milk bottle washing follows essentially the recommendations of the laboratory advisory board. These recommendations were formulated in 1926, after a preliminary field study made by the Bureau of Laboratories and Research.

In laying down basic principles for adapting mechanical and bactericidal methods to milk bottle washing, the board took the position that milk bottles, because of their extensive and constant contact with the general population, must be regarded as one of the most important potential factors in the spread of disease through milk supplies.

The primary objective, therefore, of regulations for the cleansing and sterilizing of milk bottles is the prevention of the spread of disease through milk.

The board was of the opinion that the destruction of the common pathogens which may be present in milk can be best assured by applying heat in excess of the known thermal death points of these organisms in milk at some time during the washing process. Recognizing that practical difficulties are encountered in applying this degree of heat consistently under all conditions, the board also ap-

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

† "Sterilization" as used in this article refers to disinfection rather than sterilization in the exact scientific sense.

proved the use of chlorine in the free or available state as an alternative in disinfection.

The board made the following recommendations:

1. That milk bottles be washed by soaking or agitation in a solution of free alkali, or other effective cleansing agent, in such a manner as to remove all visible foreign matter

2. That a dual temperature standard be set for washing milk bottles:

a. *Soaker method*—Exposure during the soaking, washing or rinsing process to a temperature of not less than 165° F. for 5 minutes

b. *Steam jet method*—Exposure during the process to a temperature of not less than 195° F. momentarily

3. That milk bottles washed at temperatures below those specified be subjected to a rinse of a chlorine disinfectant solution in a concentration of not less than 35 p.p.m. of available chlorine

4. That a bacterial count standard of not to exceed 1 per 2 c.c. of capacity be applied to milk bottles when the washing process is completed

In 1924, Whittaker, Archibald and Shere reported on the relative efficiency of sterilizing milk bottles by hand operated and hydraulic type bottle washers. It seemed desirable to make similar studies of the soaker type of washers now in use in Chicago and being installed in milk bottling plants, in order to test out the practicability of the advisory board's recommendations.

PROCEDURE

In these studies sample bottles were collected where possible at various stages during the cleansing and sterilizing processes, such as after soaking in caustic solution, after the brushing or pressure rinses, after plain rinsing and after sterilizing. The plating was done in the field within 5 minutes after the bottles were taken from the machine. As soon as a series of bottles was collected, the interior of each was rinsed with 20 c.c. of sterile water and the bacterial content was determined by the agar plate method as prescribed in the *Standard Methods of Milk Analysis,* American Public Health Association, 1927. From these results, the bacterial content per bottle was calculated by multiplying by 20.

In several tests, unwashed bottles were distinctively marked and contaminated heavily with a suspension of *B. coli;* these were placed in the bottle washer at the feed end and removed after passing through the soaker compartment. Marked, washed bottles were also contaminated in this manner and placed in the carriers just after emerging from the soaker solution and removed at the discharge end of the washer. Other marked bottles containing *B. coli* were inserted just before the bottles entered the final chlorine rinse. These bottles

immediately after removal were rinsed with 20 c.c. of sterile water and 1 c.c. planted in standard broth tubes and the presence of *B. coli* determined in accordance with *Standard Methods for the Examination of Water and Sewage,* American Public Health Association, 1925.

Nine different machines were tested at intervals over a period of 15 months. Bacterial counts were made on 1,885 bottles. Seven hundred and three additional bottles were tested also for the destruction of *B. coli.* During each test, determinations were made on the soaker solutions for carbonate and caustic alkalinity, also for residual chlorine in the sterilizing rinses. Temperature readings were made on soaker solutions and hot water rinses where used. The speed of operating each machine was determined. A study of the manufacturer's blue prints or cuts was made to determine the exact time of each stage of the process.

TABLE I

TREATMENTS TO WHICH BOTTLES WERE SUBJECT IN THE WASHERS TESTED

Machine	Pre-Rinse Seconds	Caustic Soak Min.	Caustic Rinses Tot. No.	Caustic Rinses Tot. Sec.	Brush and Plain Rinses Tot. No.	Brush and Plain Rinses Tot. Sec.	Steam Jets Tot. No.	Steam Jets Tot. Sec.	Tri-Sodium Phosphate Rinses No.	Tri-Sodium Phosphate Rinses Sec.	City Water Rinses No.	City Water Rinses Sec.	Chlorine Rinse Drain Tot. No.	Chlorine Rinse Drain Period Sec.	Chlorine Rinse Drain Tot. I	0	8.3	0	—	2	15	0	—	0	—	4	30	2	15	57	1.81	1.80	117	16.9
II	100	8.3	0	—	2	15	0	—	0	—	3	22	2	15	90	3.34	4.37	129	15
III	8	7.7	0	—	0	—	2	16	4	32	2	16	0	—	80	2.18	3.27	139	None used
IV	0	11.8	0	—	0	—	0	—	0	—	0	—	2	14	21	3.44	4.33	152	3.0
V	0	8.3	4	36	0	—	0	—	6	216	2	18	1	9	36	0.85	2.10	140	126.0
VI	105	6.0	6	90	0	—	0	—	0	—	3	45	2	30	135	0.80	1.80	140	40
VII	9	6.0	2	18	2	18	2	18	0	—	2	18	0	—	135	0.90	1.75	140	None used
VIII	0	20.0	0	—	0	—	0	—	0	—	5	40	0	—	88	1.60	2.10	153	None used
IX	0	10.6	3	33	0	—	0	—	0	—	3	33	1	11	99	0.89	1.40	119	17.4

The different treatments provided by the machines and length of time of each are given in Table I. The principal differences are in number of soaker compartments, whether soaking is followed by a pressure rinse of caustic solution or by brushing, whether final sterilization is provided by heat or chlorine, and in the length of time provided for the various operations. Variation will be noted also in the strength and average temperatures of the soaker solutions and the strength of chlorine solution.

RESULTS

The results of the bacteriological examination of the bottles collected at various stages in the machines are given in Table II under the headings " Average Counts," and " Per cent under 500."

Considering first the bottles collected as they emerged from the *soaker solution,* it will be noted that in one of the nine series, all of the bottles had counts under 500. The percentages on the other runs were: 99 (2), 96, 94 (2), 82, and 76.

TABLE II

* Where no samples are shown the construction of machine rendered it impractical to collect bottles at these points.

† *B. coli* contaminated bottles placed in machine to receive chlorine rinses only.

‡ *B. coli* contaminated bottles placed in machine to receive all treatments except soaking.

Considering the bottles as delivered by the machine after soaking, rinsing and sterilizing, in six of the nine series all of the bottles had counts under 500; two, 99 per cent; and one, 97 per cent. These results were considered as satisfactory compliance with the bacterial count standard recommended by the advisory board.

All bottles contaminated with *B. coli* gave negative results after being subjected to soaking or rinsing and sterilizing.

CONCLUSIONS

Field tests and observations revealed that all of the types of soaker bottle washers now in use have either provided, or can readily provide, for sterilization in a manner meeting the recommended standards, namely: exposure to 165° F. for 5 minutes, or 195° F. momentarily; or rinsing in a solution of chlorine disinfectant in a concentration of not less than 35 p.p.m. of available chlorine.

In certain instances, these observations further showed the necessity of improved plant control to make sure that the standards would be properly met. Therefore, on machines providing heat sterilization the installation of temperature control apparatus was recommended and secured; on machines providing chlorine sterilization, the plants were required to provide orthotoluidine testing kits, and the bottle washer operators were instructed to check the available chlorine at frequent intervals to assure proper dosage at all times.

Detergent Properties of Alkaline Dairy Washing Compounds*

MILTON E. PARKER

Formerly Dairy Technologist, Philadelphia Dairy Products Co., Inc., Philadelphia, Pa.

TO quote that modern classic *Fundamentals of Dairy Science:*[5] "While dairy utensils are in no sense a natural habitat of bacteria, a great many organisms grow on the surfaces of such equipment so that the utensils form an important source of bacteria in milk. As a general rule, in fact, under ordinary farm conditions where steam is not available for sterilizing purposes, more bacteria gain access to milk through utensils than from any other sources." These conclusions can truthfully be supplemented with the observation that the farmer is not the only offender in this matter.

Some of the present methods of dairy sanitation fail to give cleanliness consistent with quality standards. Cleanliness is the exception and not the rule. The presence of oily films in pipe lines, utensils, pasteurizers, holding and mixing tanks, valves and the like, can readily be detected by the finger. Wherever intense heat (particularly steam) is applied to any surface in contact with milk for an appreciable period of time, a calcareous deposit known as "milk stone" forms, which continued applications of some washing compounds fail to remove. Such surfaces are not clean and can be the sources of trouble because they provide culture medium for bacteria which may gain access between the washing and sterilizing and the passage of fresh milk.

When such conditions become troublesome, it is sometimes the practice to apply copious amounts of some chlorine disinfectant, which may be antiseptic for short periods but never germicidal, since their disinfecting properties are destroyed through chemical combination with the adhering milk solids, and the condition remains to cause future trouble. These statements, however, must not be interpreted as a condemnation of the use of chlorine disinfectants, but rather as a warning for their intelligent application.

These failures to obtain cleanliness certainly are not due to dairy

engineering, for on every hand there are appliances that should insure clean equipment and utensils. One of the most striking examples is the soaker type of bottle washer, a heritage of the brewery, yet efficient. Apparently the advances in dairy sanitation made during the past few years have been due to the contributions of engineers. On the other hand, the washing compounds so necessary to obtain cleanliness are practically the same as they were ten or even twenty years ago. Why? Possibly their inadequacy is due to failure to determine the fundamentals and to select chemicals that can meet the demands made upon them.

THE GERMICIDAL PROPERTIES OF ALKALIES

A dairy detergent must be an efficient germicide and also an effective cleansing agent. During recent years considerable attention has been given to the germicidal efficiencies of the alkaline washing compounds. Research has indicated that hydroxyl ion concentration is an important factor in the germicidal action of such compounds. This was first indicated in the work of Myers[1] and later substantiated in studies on the effect of alkali solutions on bacteria found in unwashed milk bottles by Mudge and Lawler.[2] On the other hand, work by Levine, Buchanan and coworkers has indicated that germicidal efficiency, while a direct function of the hydroxyl ion concentration, does not depend upon the degree of alkalinity alone. As the result of a study upon the germicidal efficiency of sodium hydroxide, and of sodium hydroxide-carbonate mixtures at the same hydroxyl ion concentration, these investigators suggest that the undissociated sodium hydroxide rather than the hydroxyl ion concentration might be the controlling factor in germicidal efficiency.[3] Considerable support was given this theory in their later study wherein the addition of various salts to sodium hydroxide markedly increased its disinfecting properties.[4] Their results, however, are more particularly applicable to problems where considerable concentrations of caustic can be utilized—a practice that must be avoided in a majority of dairy cleansing operations due to its corrosive action upon metals and danger of injury to individuals who may come in contact with it.

It will be found in practice that where the relatively non-corrosive alkalies are used their concentrations generally are doubtful factors in germicidal activity. It is therefore possible that more attention to the hydroxyl ion concentrations of such solutions might prove of considerable value as a public health measure. Yet, while this research has been fundamental, it has not solved the problem. The bactericidal effect of a dairy detergent is of paramount importance; yet its cleansing

properties are equally as vital, for unless the contact surfaces are free from all traces of adhering milk particles, a source of future contamination remains. Aside from the colin-aerogenes types, the alkali formers, miscellaneous non-spore-forming rods, and several species of micrococci which have been found associated with dairy utensils and equipment, there are instances where spore-forming bacteria have been added to milk in significant numbers from pasteurizing equipment because inadequate cleansing permitted their growth in the milk solids which had cooled on the exposed surfaces.[6]

DAIRY CLEANSING PROBLEMS

In dairy cleansing problems, there are normally three classes of "dirt" that a detergent has to remove: (1) particles of dirt or milk solids held to the surfaces by an oily or greasy binder of milk fat; (2) the dirt or milk solids held by adsorption to the surfaces; (3) the "milk stone" deposits accumulated on surfaces subjected to intense and intermittent heat applications.

THE ELIMINATION OF FATTY FILMS

The emulsification of the milk fat will break the binder holding the entrapped particles and render their removal (as well as that of the dispersed fat) by rinsing an easy matter. Soap solution possesses cleansing properties of this character but is inadequate because of precipitation and other chemical reactions. Of the alkalies commonly used in dairy washing compounds, sodium hydroxide, tri-sodium phosphate, sodium carbonate and bicarbonate constitute the bulk of the supply. Caustic soda because of its corrosive nature is objectionable and its applications are limited.

When melted milk fat is added to tepid water and shaken vigorously, droplets of fat form, which quickly join together as a layer of fat on the surface. If a 1 per cent aqueous solution of tri-sodium phosphate is used, a more or less opaque mixture results, and not until several minutes have elapsed will a film form at the surface. When chemically pure sodium carbonate or bicarbonate is used, almost immediately droplets of milk fat larger than those discernible in the phosphate solution will rise to form a film. A mixture of c.p. sodium carbonate and tri-sodium phosphate, as well as commercial products containing these two, will dissipate the emulsifying property of the phosphate at the expense of the carbonate.

By adding equal quantities of melted milk fat to given aliquots of 1 per cent aqueous solutions of the alkalies to be tested, at a constant temperature, it is possible to evaluate relative emulsifying properties

by measuring the size of the droplets rising to the surface, and determining the time consumed in forming fat layers of uniform thickness. In the author's experience 45° C. is the most practical temperature for these tests. It is suggested that the water supply used in the washing operations be used as the solvent in order to approximate practical conditions.

The author's experience is that crystalline tri-sodium phosphate is the most efficient of the alkalies studied. Mixing this with sodium carbonate or bicarbonate, or using mixtures containing them invariably dissipated the emulsifying properties of the phosphate. Sodium hydroxide gave the same results.

THE SUSPENSION OF DIRT PARTICLES

The removal of adherent dirt particles and milk solids can best be accomplished by their suspension in the detergent solution. While soap solutions owe their cleansing power in part to this property of colloidal suspension (i.e., adsorption), their use is limited because of the difficulties mentioned above.

If finely divided charcoal (freed from oil or grease by washing with ether) is added to water and shaken, it settles. If a 1 per cent aqueous solution of c.p. tri-sodium phosphate or sodium hydroxide is used, the charcoal will remain in suspension and the liquid will resemble ink. The particles of carbon are so fine that instead of forming a precipitate, they attach themselves to the alkalies and remain suspended. This action looks like disintegration but is not. If a suspension of carbon black in water is filtered several times through paper, the water will finally run through clear, while the carbon black will be held back. If a solution of sodium phosphate or hydrate is then poured on the filter, a black filtrate is obtained and the paper becomes clean. The cellulose adsorbs the carbon black and clogs the filter so that the pores are not large enough to let the remaining particles through. The alkali solutions remove the carbon black because it is more strongly adsorbed by them, and, therefore, goes through the paper. That this is the explanation can be shown in three ways: (1) The experiment does not succeed if the carbon black is too coarse; (2) if the black filter paper is reversed and washed with water, it will remove only the carbon black that is not in immediate contact with the paper; (3) microscopic examination of the black filtrate will reveal the presence of charcoal particles.

The adsorption of carbon black by filter paper offers a means of determining the relative dirt suspending powers of alkaline washing compounds. If a strip of filter paper is dipped into an aqueous sus-

pension of carbon black, the charcoal will not spread appreciably although the water will rise over a considerable area. If, however, a strip of filter paper is dipped into suspension of carbon black adsorbed by an alkali, the charcoal will spread nearly as far as the liquid, because it is more strongly adsorbed by the alkali than by the filter paper. By dipping uniform strips of filter paper into comparable test suspensions of carbon black for a given period of time, we have a means of evaluating the relative dirt suspending powers of the different detergents being studied. No particular attention need be given the temperature except that it is constant in all the tests. The filter paper should just touch the surface of the test suspension. A detergent solution which gives an area of blackness on the filter paper equal to that of adsorbed liquid is more efficient than one which gives a fainter color or a smaller black area.

It has been found that c.p. tri-sodium phosphate crystals proved superior as a suspensory agent. Sodium hydroxide was practically as efficient as tri-sodium phosphate. Sodium carbonate and bicarbonate were markedly inferior to these two alkalies. Mixing the chemically pure phosphate or hydrate with either the carbonate or bicarbonate decreased the adsorption properties of the former. Commercial products containing mixtures of the phosphate or hydrate with the carbonates produce suspensions inferior to those of the c.p. phosphate or hydrate but superior to those of the c.p. carbonate or bicarbonate.

THE PREVENTION OF " MILK-STONE " DEPOSITS

While the calcareous deposit of so-called " milk stone " has been considered as a third class of dirt encountered in dairy cleaning problems, it is more properly the product resulting from the reaction of certain constituents of commercial washing compounds with the calcium salts found in " hard " water, but involving the protein of milk, which apparently hastens its formation.

The first explanation for the formation of this shell-like incrustation is found in the well known treatment of " hard " water whereby calcium carbonate is precipitated by the addition of sodium carbonate. This, however, does not account fully for this formation, as casein is precipitated by calcium salts such as are found in " hard " water. Slightly sour milk coagulates upon boiling, which explains the formation of the original coagulum found on pasteurizer coils. Apparently a localized acidification aided by the intense heat is the contributing factor. Casein, not unlike charcoal, is peptized by alkalies. The peptizing action of the alkaline earths is less marked than that of the alkalies because the adsorption of the bivalent cations cuts down the

peptizing action of the hydroxyl. When peptized by hydroxyl, casein is precipitated by calcium salts.

In view of these facts and their relation to the problem of dairy detergency, involving as it does the use of " hard " water containing calcium salts varying with the locality, a few experiments with casein were undertaken. Since in practice the milk coagulated on the surfaces of pasteurizers, coils, etc., represents a relatively high concentration of casein, tests were conducted using as high as 1 gm. of purified casein with only 50 c.c. aliquots of 1 per cent aqueous solutions of the various alkalies and commercial products studied. In all of these experiments large test tubes with their contents were heated to 180° F. and agitated gently before any observations were noted. In this way it was assumed that the soaking of equipment to be cleansed would be approximated.

It was found under the conditions of these experiments that c.p. caustic soda formed an apparent solution with casein while crystalline tri-sodium phosphate peptized most of the casein with the formation of a flocculent precipitate that settled only as the temperature was lowered. The carbonate and bicarbonate produced a less marked peptization with the formation of a sandy precipitate. These experiments were then repeated with the addition of very small and uniform amounts of calcium sulphate (approximately 0.03 per cent) in order to establish an exaggerated and artificial " hard " water condition. While similar results were obtained as regarded the peptization of the casein, the tubes containing the hydrate, carbonate and bicarbonate had turbidities that were not detected in those containing the phosphate. Upon the completion of these tests, it was noticeable that the tubes containing the bicarbonate and carbonate solutions were coated on the inside with a rough calcareous deposit resembling " milk stone." Vigorous rubbing failed to dislodge this incrustation but it was readily dissolved by hydrochloric acid. Furthermore, soaking these tubes with hot solutions of phosphate after first removing all superficial material by thorough rinsing soon made it possible to remove such deposits with a little brushing.

While the adsorption of hydroxyl ion accounts for the degree of peptization of casein by the alkalies studied, it is difficult to explain its apparent protective colloidal action in the presence of phosphate and its precipitation by the calcium sulphate in the carbonate and bicarbonate solutions. It is possible that in the phosphate tests, a colloidal solution of calcium phosphate was formed through its adsorption by the casein. Carbon black is similarly adsorbed by casein and more strongly so than any of the alkalies studied.

It was found in these experiments on " milk stone " that only crystalline tri-sodium phosphate would prevent its formation. Mixing this with any of the other alkalies, as well as using commercial products containing mixtures of these alkalies, would invariably result in the formation of " milk stone."

DISCUSSION AND SUMMARY

While the few experiments outlined are concerned primarily with detergency from the standpoint of the elimination of " dirt," there is another phase which has not yet been properly investigated. It is conceivable that the phenomena of emulsion and adsorption increase the penetration of the germicidal substances to the bacteria entrapped in greasy films or adhering to " dirt " particles and the equipment. In addition, spore-formers or other resistant microörganisms might possibly be eliminated if adsorbed either by the detergent solution or by " dirt." Some indications of this were seen in the results of an investigation of a colloidal alkali mixture used in cleaning milk bottles.[6] It was demonstrated in field experiments with an automatic bottle washer, that a colloidal-alkali mixture containing caustic soda was more effective germicidally than caustic soda used alone. Thus it appears that the " availability " or " penetration " of the lethal agent increases germicidal efficiency.

From the reported observations upon the detergency of the alkalies and commercial products, it has been indicated that crystalline tri-sodium phosphate has chemical and cleansing properties which particularly recommend it for use in dairy detergency. Mixing the phosphate with carbonate or bicarbonate is objectionable as such admixtures will diminish its emulsifying properties; reduce its power of adsorption; and induce the formation of " milk stone."

It appears from the results obtained that chemical purity is vital if consistent cleansing action is to be assured. Apparently the satisfactory method for preparing a dependable dairy detergent involves the synthesis of chemicals possessing a degree of chemical purity formerly regarded as unnecessary. If dairy cleansing processes are to acquire a stability now lacking in most instances, it is essential that the same discrimination be exercised in the selection of the detergent as in choosing the alkalies used in baking powder in contrast to those used in an agricultural fertilizer.

Results Obtained in Phenolic Wastes Disposal under the Ohio River Basin Interstate Stream Conservation Agreement*

F. HOLMAN WARING

Chief Engineer, State Department of Health, Columbus, O.

PHENOL and other tarry acids, the sources of great annoyance in water supplies, originate in the coking of coal. This enterprise is as old as the manufacture of steel; and coking follows steel manufacture in the growth of its importance.

Twenty-five years ago practically all coke was made by the beehive process. No effort was made to recover by-products; hence there were no problems incident to recovery and refinement of coal gas and coal tar products. A few years prior to the outbreak of the World War the situation began to change. Steel companies began installing ovens of the by-product type, and many millions of dollars worth of by-products formerly consumed and wasted were salvaged, chiefly ammonia, tar, benzol, naphthalene and toluol solvents.

Following 1914, a great impetus was given the industry, through the loss of shipments from Germany, and the manufacture of war materials demanding many ingredients derived from coal tar products. All coke ovens built in the last 10 years are of the by-product type; and fully 75 per cent of coke manufactured is from the by-product oven.

LOCATION OF BY-PRODUCT COKE WORKS

Because coke is utilized largely for supplying carbon in the manufacture of steel, coke plants are largely located near iron and steel centers. The steel industry selects its location for the minimum transportation expense of both raw and finished materials. Coal is a most important raw material. The most notable of these centers is the Pittsburgh district, embracing the upper Ohio River valley, western Pennsylvania, and northeastern West Virginia. The Youngstown district, also on the Ohio River drainage area, is an important location for this industry. Two other large centers are the Cleveland district in northeastern Ohio on Lake Erie, and the Chicago district at the southern shore of Lake Michigan. Proximity by way of easy transportation to the iron ore, and easy reach to the markets for the finished steel product, have made for the rapid and extensive development of these two centers of the steel industry.

A number of factors have influenced the locations of the newer by-product coke plants that are not associated strictly with the manufacture of steel. Manufacture of domestic coke, favorable sale of fuel and illuminating gas, and cheap transportation of high-grade coal are the more important influences. A center of such char-

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

acter is located on the Ohio River in the vicinity of the junction of West Virginia, Ohio, and Kentucky. It is also probable that with the decline in the supply of natural gas in this region a more intensive development of the by-product coke industry will take place.

SOURCE OF PHENOLIC WASTES

Liquid wastes result from the coking of coal and the recovery of by-products in the following manner: The hot gases driven from the coal during coking must be cooled before the product may be utilized for fuel or illuminating purposes. In the coking process a condensate of water, ammonia, oil and tar is produced.

The most common type of by-product coke plant employs the indirect method whereby the cooling water is circulated in pipes around which the hot gases pass to form a condensate which is then removed for refining of valuable constituents. Further cooling and refining follows when the gas is bubbled through sulphuric acid where the free ammonia is transformed into ammonium sulphate. Final cooling and refining of the gas is afforded by a direct scrubbing with cool water followed by a direct scrubbing with cool oil, whereby the benzol, naphthalene and light oils are removed from the gas. The condensate from the preliminary cooling of the gas is treated with lime and distilled for the additional production of ammonia. This type of plant is usually designated a sulphate plant, owing to the manner in which the ammonia is recovered and marketed. It is the residues from the ammonia stills that contain the phenolic substances which must be disposed of.

The other type of by-product coke plant, less common than the above, differs in process by the employment of direct scrubbing with water for gas cooling and refining and for production of ammonia. After separation of tars and oils by gravity, the entire volume of cooling water thus becomes weak ammonia liquor and must be distilled for concentration of the liquid ammonia. The tars separated from the scrubbing of the gases are treated with lime; and, combined with the residue from the free ammonia still, are further distilled to procure the fixed ammonia. This type of plant is ordinarily designated a liquid ammonia plant, because all the ammonia is recovered and marketed as aqua ammonia. Again, the residues from the ammonia stills, which contain the phenolic substances, must be disposed of. An important item of note is that the volume of still wastes to be disposed of in this process is greater, perhaps 3 to 4 times that of the sulphate plant.

Until comparatively recent years it was the general practice to discharge these still wastes untreated, directly into the rivers, streams, and lakes adjacent to the by-product coke plants. In numerous instances these bodies of water were the sources of public water supplies, in such close proximity as to be affected thereby and become the objects of serious complaint.

EFFECT OF PHENOLIC WASTES UPON PUBLIC WATER SUPPLIES

Phenolic substances, even when present in minute amounts, impart to water a taste and odor that may be decidedly objectionable. When unaffected by other chemical agents these phenolic substances give to the water a " carbolic " or medicinal flavor. In contact with chlorine, used extensively in water purification practice, the chloro-phenol gives to the water a sort of iodoform taste and odor even more objectionable and far reaching. Observers are generally agreed that these tastes and odors are developed with the phenolic wastes in contact with ordinary filtered and chlorinated water in dilutions as great as 1 part of phenol to 50 million parts of water.

From a public health standpoint these phenolic wastes may possibly have the following ill effects: (1) The presence of phenol in drinking water may exert directly a deleterious effect upon the health of persons using such water (Elyria and East Liverpool, O.). (2) The existence of an offensive taste and odor discourages the use of water for drinking in the amounts necessary to promote health. (3) The existence of such tastes and odors likewise encourages the use of other sources of water supply which, while of pleasing physical quality, may be contaminated and unsafe (Ironton, O.). (4) The fact that chlorine treatment of a public water supply intensifies the tastes and odors, may result in a reduction of the amount of chlorine used or the total suspension of the chlorine treatment and consequent failure to secure sufficient disinfection.

Early experiences with phenolic tastes and odors in drinking water supplies resulted of course in much embarrassment to water works officials charged with the duty of furnishing pure and potable water to the public. Every effort was made to find some method adapted to water purification practice whereby the phenolic substances could be successfully modified or removed. Very little or no success has attended the years of constant research along these lines. A certain degree of relief from the intermittent occurrences of phenolic tastes has been attained at those places where the most elaborate and double treatment devices permitted temporary cessation of chlorination in the water purification process; or where lime softening could be substituted for chlorination to bring about the disinfection of the water supply. However, if the concentration of the phenolic wastes became great enough, the tastes and odors again were the source of complaint. The margin between the amount that would only cause trouble in contact with chlorine and that which would alone be objectionable was not enough to make dispensing with the use of chlorine in water treatment practice a satisfactory solution to the problem.

EXPERIENCES WITH PHENOLIC WASTES AND EARLY EFFORTS OF INDUSTRY TO ERADICATE THEM

From the foregoing remarks concerning the history and location of the by-product coke industry, it is not surprising that the first difficulties incident to disposal of wastes from this class of industry originated in the upper Ohio valley. One of the earlier cases on record was at Newcastle, Pa.[1] In December, 1912, the city experienced a severe occurrence of phenolic tastes and odors in the public water supply lasting six or seven weeks. Legal proceedings were instituted by the Newcastle Water Company against the Carnegie Steel Company of Farrel, Pa., which resulted in a financial settlement and an agreement on the part of the steel company to prevent further disturbance. The objectionable wastes were eliminated by the installation of a coke quenching system completely utilizing these wastes.

At Johnstown, Pa., the Cambria Plant of the Bethlehem Steel Company, at the instance of the Pennsylvania Department of Health, installed, early in 1916, a quench system to dispose of the phenolic wastes in order to protect the Conemaugh River, a tributary of the upper Ohio, from which stream the city took its public water supply.

Likewise at Clairton, Pa., the Carnegie Steel Company installed, in 1918, a quench system for eliminating the phenolic wastes from the Monongahela River, also in the upper Ohio River valley, from which McKeesport, Pa., takes its water supply a few miles downstream from Clairton. The installation at Clairton serves the largest by-product coke plant in the world, the coal coking capacity at this

works being 30,000 tons per day, or about 6 times that of a plant ordinarily considered a large one.

Other cities in the country experienced periods of marked phenolic tastes in public water supplies in early years. As early as 1917 Cincinnati complained of this trouble and in 1918 and 1919, Morgantown, W. Va., Youngstown, O., Louisville, Ky., and other Ohio River cities also began to complain. Outside of the Ohio River drainage area bad reports were heard—Milwaukee, Cleveland, Rochester, Buffalo, and more recently Chicago and the other cities in the southern Lake Michigan district.

The Cleveland experiences of 1922 and 1923 were particularly aggravating, and culminated in the installation of quench systems for the elimination of phenolic wastes by three companies, the American Steel & Wire Company, the McKinney Steel Company and the Otis Steel Company. All three formerly discharged untreated wastes into Cuyahoga River, which entered Lake Erie a few miles from Cleveland's water intakes.

APPLICATION OF INDUSTRIAL SCIENCE TO THE PROBLEM

The so-called quench system, while seemingly quite simple, and satisfactory from the standpoint of protecting water supplies, is far from satisfactory to industry. The initial expense of installing the quench system for a new by-product coke plant is negligible, merely that of arranging the sewer system on the separate plan whereby all phenolic waste waters flow to a central sump or storage basin from which they are pumped to the coke quenching tower. For a by-product coke plant already established it may mean a very considerable expense to rearrange the sewer system, often involving the pumping of the flows two or more times. At one plant of the Youngstown Sheet and Tube Company this initial expense of rearrangement cost in the vicinity of $250,000 for a coke plant of 5,000-ton daily capacity.

The maintenance of a quench system is costly. The phenolic wastes are corrosive, and attack the metal piping and pumping equipment, also the quench tower metal parts, quench cars, tracks, and draining platforms. The life of the equipment, variously estimated at 7 to 10 years when using clean water for quenching, is cut to 2 to 4 years when using phenolic wastes. At the largest by-product coke plant in the world, Clairton, Pa., with a 30,000-ton daily coking capacity, the maintenance expense averages $60,000 annually.[2]

The quenching system is chiefly objectionable to industry because of the bad effects of the phenolic wastes upon the coke produced. In spite of a considerable volume of clean make-up water being required daily, an objectionable phenolic odor is imparted to the coke thus quenched, making it unfit for the domestic trade; that is, the customers simply will not stand the odoriferous material in their cellars. In the case of the liquid ammonia type of plant, where the total volume and amount of phenolic materials are from three to four times that of the sulphate of ammonia type, it becomes difficult to use up all of the liquid by the quench operation; with the result that the coke receives a stronger odor and is made soggy with moisture. The excess of moisture impairs the quality of the coke for the furnace trade and the manufacturer suffers accordingly.

The foregoing unsatisfactory experiences with the quench method of eliminating phenolic wastes have compelled industry to devote intensive study and research to this problem. American practice following the World War has developed means of refining further valuable constituents from the coal tar residues, including the

commercial extraction of phenol. The first attempt on a plant scale to be demonstrated in this country was the so-called benzol extraction process of phenol recovery installed by the Lorain, O., plant of the National Tube Works in 1924.[3] This by-product coke plant has a daily coking capacity of about 4,200 tons. Briefly, this type of recovery process comprises means for scrubbing with benzol the ammonia liquor from which the free ammonia has been distilled, but before the addition of lime for distilling off the fixed ammonia. The benzol absorbs or carries the phenol constituent of the liquor; subsequent separation of the phenol from the benzol carrier is accomplished by scrubbing the benzol with caustic soda, which converts the phenol to sodium phenolate, permitting gravity separation from the benzol. The benzol thus freed from the phenol is returned for additional carrier duty and the sodium phenolate neutralized with acid to free the phenol, or otherwise refined.

Following the experiences of the Lorain plant, similar works were installed at Buffalo and Troy, N. Y., in 1925 and 1926 respectively; and at Fairmont, W. Va., in 1927. Certain refinements in mechanical detail were perfected and different capacities in the absorbers and scrubbers employed; otherwise the Lorain experience was followed. As a result of the refinements, the percentage of phenol recovery was increased from 70 to 75 per cent, attained originally at Lorain, to 95 to 98 per cent at Fairmont. An estimate of the expense of installation and operation for the Fairmont plant was given to the Third Annual West Virginia Conference on Water Purification (1927) by Hugh E. Jones, chemical engineer of the Domestic Coke Corporation.[4] The daily coking capacity of the Fairmont Works is about 1,000 tons. The initial cost of the phenol recovery plant was about $25,000, and the cost of maintenance and operation is said to about equal the sale value of the phenol recovered. The success of the Fairmont plant is attested by the experience of the Morgantown, W. Va., water works, 20 miles downstream on the Monongahela River, as reported by Prof. W. W. Hodge of West Virginia University;[4] namely, the public water supply no longer contains objectionable phenolic tastes and odors.

Three other types of phenol recovery plants have been installed in the Ohio River valley. In April, 1928, the Midland, Pa., plant of the Pittsburgh Crucible Steel Company, with a coking capacity of 1,800 tons daily, placed in operation the Heffner-Tiddy process. In this method a preliminary scrubbing with benzol of the ammonia liquors containing the phenol is proposed to recover perhaps 60 per cent of the phenol, as already described for the Lorain and Fairmont plants. However, this preliminary treatment with benzol and subsequent recovery of phenol as sodium phenolate has not as yet been provided at the Midland plant. The ammonia liquor simply passes to a specially constructed ammonia still wherein the ammonia concentrations, and temperatures between 98° and 103° C., are controlled so as to cause the phenol to go over as ammonium phenolat . What becomes of the ammonium phenolate has not yet been definitely established. It may pass on through with the gas and be consumed; it may escape to the atmosphere in the cooling of the final cooler water; it may remain behind in the saturator; or it may contaminate the light oils. Data on the cost of installation and operation have not yet come to the attention of the writer. Also it is perhap soon to state what success has attended this installation. The patent owners expect to obtain from 95 to 98 per cent removal efficiency.

In May, 1928, the Ironton, O., plant of the Ironton By-product Coke Company, with a daily coking capacity of 1,300 tons, put into service a phenol recovery proc-

ess somewhat similar to the benzol type already described, except that light oil is used for the carrier instead of benzol. Since the Ironton plant does not manufacture benzol, the "light oil" type seems particularly adapted. Because the Ironton plant is also a liquid ammonia type of by-product coke plant, handling several times the volume of phenol bearing liquid handled by the sulphate type, the capacities of the scrubbers and absorbers are correspondingly larger; and furthermore because light oil is used in place of benzol these capacities have been specially worked out and may differ somewhat from those where benzol would be used. The phenol recovery plant at Ironton cost about $65,000 to install. Operation costs have not yet been released. Results for the first two months of operation have shown 90 to 95 per cent efficiency of phenol recovery; and expectations are for 95 to 97 per cent efficiency.

In September, 1928, the Hamilton, O., plant of the Hamilton Coke & Iron Works, coking capacity 1,200 tons daily, installed a phenol recovery process of the Koppers type. This process will probably be described more fully in another paper. Briefly, the process involves ordinary ammonia stills with careful heat control between 98° and 102° C. The liquor, from which the free ammonia has been driven, is pumped to the top of a scrubber through which steam and gas in large volume are passed. The phenol is volatilized and thus separated in a gaseous state from the liquor, which proceeds to the fixed ammonia still. The volatilized phenol is then absorbed in caustic soda scrubbers. The cost of this particular installation is understood to be in the vicinity of $40,000. Efficiency of phenol removal is claimed for this process of 95 to 98 per cent. Residues from the process will be evaporated upon the hot slag dump having an interior sump with no outlet to the river.

REACTION OF THE PUBLIC TO THE PROBLEM

It is not a difficult matter to determine what the public's attitude is toward a situation of this kind. Past experiences have been too numerous to recite where the public water supplies have been injured with phenolic tastes and odors. In a survey of such conditions in the Ohio River valley, H. R. Crohurst, of the U. S. Public Health Service, found in 1924[5] that 25 public water supplies were already badly affected and at least 25 more were likely to be, as a result of the operation of some 19 by-product plants within the area. Outside of the Ohio River valley important disturbances at various times have occurred at Cleveland, Buffalo, Milwaukee and Chicago in the Great Lakes area; and at Rochester, Troy and other places in New York.

Summing up the situation from a popular standpoint, there appears to be an immediate demand for complete relief. This demand usually is insistent and compelling, and more than likely may result in hasty and ill-advised actions. Most certainly, if the disturbances are frequently recurring, and if steps are not taken to alleviate the conditions, the public demands result in drastic action either embarrassing to industry, to public officials, or to both. As far as the public is concerned the end result is what counts and must be obtained; namely, a water that is not rendered unpalatable for drinking nor offensive for culinary and other domestic purposes.

The public ire is first directed toward the local water works officials, who are blamed for "doping" the water unnecessarily with the chemicals used in ordinary water purification practice. Frequently hasty removal of water works officials results, or attempts are made in this direction. Eventually the public learns that

these officials are not to blame and ire is next directed toward administrative officers having jurisdiction over the supervision and protection of public water supplies; thus local health officials and state health department officers are drawn in. The usual cry is for the industry causing the trouble to be forced to stop all operations forthwith; if legal powers are not deemed sufficient, make them so; or obtain injunctions to restrain the industrial operations causing the objectionable contamination. Failure to act thus and immediately seems to inspire in the average mind a contempt for the local or state official. Too often the public cannot understand why the problem cannot easily be solved, and solved permanently, by such simple expedients as passing new laws or local ordinances or asking the federal government to enact and enforce prohibitory legislation.

It takes courage on the part of administrative officials to embark upon any sensible plan of coöperation with industry in the study and formulation of a logical means of eliminating the stream pollution evil and at the same time be fair to all parties concerned. Much energy must be spent in educating the public and explaining the wisdom of concerted and coöperative action with industry. Recently the Ohio and Kentucky Health Departments have experienced particularly trying situations at Cincinnati and Louisville respectively. Federal legislation proposed by Cincinnati representatives was openly contested by the health authorities as not being the adequate or sensible way of eliminating the phenol, or any other pollution problem, especially in view of results being attained by other means.

ATTITUDE OF ADMINISTRATIVE OFFICERS CHARGED WITH WATER SUPPLY SUPERVISION AND PROTECTION

The present coöperative attitude of the health department officials of the states in the Ohio River basin is the result of a progressive development beginning in 1923. The earlier experiences of Pennsylvania Health Department officials in dealing with the situation at the Cambria plant of the Bethlehem Steel Company at Johnstown, Pa., and later at the Clairton plant of the Carnegie Steel Company were studied by the Ohio Health Department officials and found to be productive of the desired results without recourse to legal proceedings or other possible antagonistic methods. It was decided to try out the coöperative method with industry in the case of the Cleveland disturbances of late 1922 and early 1923. At about the same time the Surgeon General of the U. S. Public Health Service was asked to call into conference the officers of all states in which the phenolic wastes problem existed, in order to learn the extent of the problem and to consider ways and means to care for the same. Such a conference was held at Washington, D. C., May 18, 1923, and again January 29, 1924.

In the meanwhile the Ohio Health Department officials were putting into practice in the Cleveland district the idea of coöperation with industry. The late Judge E. H. Gary, chairman of the Board of Directors of the U. S. Steel Corporation, assured Dr. John E. Monger, Director of Health of Ohio, that he might expect 100 per cent coöperation and prompt application of remedial actions not only in the Cleveland district but at any other locality where the U. S. Steel or subsidiaries were operating.

Based upon such a splendid response from industry and as a result of previous conferences with the U. S. Surgeon General, an interstate conference was called at Pittsburgh, Pa., on April 14, 1924, attended by health department officials and all of the by-product coke plant officials located in the Ohio River basin. The importance of the problem was thoroughly discussed; also practical ways and means for

eliminating the objectionable wastes. The industrial officials agreed that immediate action on their part was required and pledged complete coöperation to rid the Ohio River and its tributaries of phenolic wastes as promptly as possible. The health department officials in turn pledged their coöperation through uniform policies and reasonable requirements.

Pursuant to these earlier conferences and understandings the State Health Commissioners of Ohio, Pennsylvania and West Virginia met at Pittsburgh, Pa., November 17, 1924, and entered into formal agreement for a uniform policy of conservation affecting the interstate streams of the three states named.

OHIO RIVER INTERSTATE STREAM CONSERVATION AGREEMENT

By the terms of this original compact it was agreed—

> That the Departments of Health of Pennsylvania, Ohio, and West Virginia, represented respectively by the Secretary of Health of the Department of Health of Pennsylvania, the Director of Health of Ohio, and the Health Commissioner of West Virginia, hereby agree to coöperate in carrying out a policy for the conservation of the interstate streams in these states, including the correction and prevention of the undue pollution thereof, to the end that the said streams may be rendered and maintained as suitable sources of public water supplies as aforesaid.

By way of a supplement Kentucky was made a party to the agreement at a conference held in Pittsburgh, February 18, 1926. Also by supplement the states of New York, Maryland, Illinois, Indiana, and Tennessee were made parties to the agreement at a conference held in Pittsburgh, September 27, 1926, and in 1928 by supplement the states of North Carolina and Virginia were also made parties to the agreement.

Although the agreement had its inception on account of the phenolic wastes problems its terms were purposely made much broader. A gradual expansion of the workings of the agreement led to the adoption of a resolution on the part of the several health commissioners, signators to the Ohio River Interstate Stream Conservation Agreement, at a conference in Cincinnati, October 18, 1927. This resolution constitutes an important explanation of the working of the agreement and is therefore quoted:

> WHEREAS it is necessary to adopt certain policies and procedures in order effectively and efficiently to carry out the letter and the spirit of coöperation and conscience upon which the Ohio River Interstate Stream Conservation Agreement is founded, therefore be it
>
> RESOLVED that the following policies and procedures be adopted as part of the said agreement.
>
> 1. The Chief Engineers of the Departments of Health, signators to the Ohio River Interstate Stream Conservation Agreement, shall constitute the "Board of Public Health Engineers of Ohio River Basin" hereinafter referred to as the Board.
>
> 2. The Board shall meet at least annually during the first week of December and shall recommend, from time to time as may be deemed necessary, to the Health Commissioners, signators to the Agreement, ways and means for effectively and efficiently carrying out the letter and the spirit of the Agreement.
>
> 3. As adequate protection of public water supplies from damage caused by phenol and other tarry acids discharged into the source of such supplies requires substantially complete and continuous elimination of the discharge of wastes containing such constituents, or substantially complete and continuous removal of such constituents prior to discharge; therefore the signators of the Agreement should promptly institute action to require such elimination or removal by suitable treatment prior to discharge.
>
> 4. The signators to the Agreement will notify promptly downstream or adjacent signators of unusual events affecting the Ohio River or its tributaries, such as phenol

spills, typhoid fever epidemics, etc., in order that suitable measures may be taken by such downstream or adjacent signators to the Agreement as are needful to protect the public health.

5. The signators to the Agreement, in matters relevant thereto, will coördinate present and proposed research, exchange data derived therefrom, and exchange ideas on administrative policies for mutual benefit.

6. The signators to the Agreement will furnish to downstream or adjacent signators data concerning discharge of sewage or industrial wastes or the treatment thereof in cases where such matters might prejudicially affect such signators in order to obtain thereby the views and judgment of such downstream or adjacent signators.

7. Any signator to the Agreement invoking the provisions thereof for abatement of alleged harmful pollution shall first establish the fact that the cause of the alleged harmful pollution does not exist within its own jurisdiction but does exist within the jurisdiction of the upstream or adjacent state.

8. The signators to the Agreement in matters involving mutual concern will arrange for joint inspections of water works, alleged pollution of interstate streams, the alleged effects thereof, the stream involved therein, proposed remedies, and reports thereon whenever deemed necessary.

ACCOMPLISHMENTS UNDER THE OHIO RIVER INTERSTATE STREAM CONSERVATION AGREEMENT

As stated previously, elimination of phenolic wastes was the dominant factor in the creation of the Ohio River Agreement. It is pertinent therefore to call attention to accomplishments in this direction, although space will not permit me in this paper to recite in detail certain other accomplishments. Appended will be found a chronological tabulation of data relating to the establishment of by-product coke plants and phenolic wastes elimination devices for all such plants on the Ohio River watershed grouped by states. The chief engineer of the health department of each state is the authority for such data.

It will be noted that Pennsylvania first installed phenolic wastes elimination devices utilizing the quench system. Five plants are located in Pennsylvania in the Ohio River basin, 4 of which installed the quench system prior to the signing of the formal agreement in November, 1924. The fifth plant, that of the Pittsburgh Crucible Steel Company at Midland, installed the Heffner-Tiddy process of phenol recovery April 25, 1928. This action was pursuant to an order of the Sanitary Water Board of Pennsylvania as part of the execution of the Interstate Agreement. The plant is located almost at the Pennsylvania-Ohio state line and affects no Pennsylvania water supply interests. Thus it will be seen that as far as the Ohio River basin is concerned Pennsylvania is taking care of phenolic wastes 100 per cent.

In Ohio none of the 9 by-product coke plants in Ohio River basin had provided for treatment or proper disposal of phenolic wastes prior to 1924; today all have complied with the requirements. Seven are quenching and 2 are recovering phenol. Phenol recovery by the "light oil" method is being practiced by the Ironton By-product Coke Company, Ironton, and by the "Koppers" method at the Hamilton plant of the Hamilton Coke & Iron Works. One or two of those plants now maintaining quench systems are experimenting and studying phenol recovery processes with a view to installing the same at an early date. Thus it will be noted that Ohio has reached 100 per cent in installing phenolic wastes treatment and disposal plants in the Ohio River basin.

Kentucky has but 1 by-product coke plant, located on the Ohio River at Ashland. Pursuant to the terms of the Agreement this company was ordered by the

Kentucky State Board of Health to provide proper disposal of the phenolic wastes, and in compliance therewith has practically completed a phenol recovery works of the " light oil " method. The date for beginning operation is October 31, 1928.

West Virginia has 4 by-product coke plants in the Ohio River basin. One discontinued operation late in 1926. One installed the quench system in order to comply with notifications of the State Health Department; although recent advices are that this plant, of the Weirton Steel Company, has discontinued the quenching operations. Another, the Domestic Coke Corporation of Fairmont, installed, in January, 1927, the " benzol " method of phenol recovery. The remaining one, the Wheeling Steel Corporation at Follansbee, as yet has made no proper disposition of the wastes. It is fair to state, however, that following recent representations on the part of the West Virginia Health Department, the Wheeling Steel Corporation has agreed to install a suitable phenol recovery process, probably following either the " Koppers " or the " benzol " method.

Summing up the Ohio River basin situation, it will be noted that of the 18 plants having phenolic wastes for disposal only 2 have not complied with the requirements regarding the installation of phenol elimination devices.

In addition, the companies operating the phenolic wastes elimination devices who have thus far been approached upon the subject have agreed to report regularly to the several health departments concerning the operation of the plants. In particular, data will be furnished on efficiencies of phenol recovery, tests for phenol in the receiving streams, and prompt information about accidental phenol spills.

NEED FOR SIMILAR REMEDIAL MEASURES ELSEWHERE

Outside of the Ohio River basin there exists need for similar remedial measures. In Ohio there are 6 by-product coke plants on Lake Erie drainage area, 5 of which are operating satisfactory quench or recovery devices; the one at Toledo apparently does not now deleteriously affect any water supply interests, but is investigating a possible recovery installation or other means for the treatment of its phenolic wastes.

New York and Pennsylvania have by-product coke plants, not on the Ohio River watershed, some of which have given concern. Relief measures have been instituted or are under way in most of these cases.

In the southern Lake Michigan district the need for relief has been felt keenly during the past year. Following the precedent of the Ohio River Interstate Stream Conservation Agreement a similar one has recently been effected known as the Great Lakes Drainage Basin Sanitation Agreement.

SUMMARY AND CONCLUSIONS

The results obtained in phenolic wastes disposal under the Ohio River Basin Interstate Stream Conservation Agreement have demonstrated the usefulness and wisdom of this plan. Uniformity in policies, close coöperation of personnel, exchange of information and data, joint actions where the occasion warrants, all make for an effective instrument. Although state laws in many instances grant full authority within their own borders, nevertheless the above mentioned agreement sets forth mainly a program of coöperation between states and with the industrial interests of these states, without detracting from legal means for compelling action that may be warranted in certain cases.

Industry appreciates and demands utmost frankness and fair dealing. It understands that the public interests are paramount and knows that it cannot

affront public opinion, or ignore its righteous demands for relief such as result from offensive pollution of public water supplies.

In setting forth to the by-product coke industry the requirements of the situation in the Ohio River valley, the states, through their health department officials, have tried to be reasonable both as to results to be obtained and in the time allowed for perfecting individual arrangements. As far as phenolic wastes are concerned the criterion of removal has been declared to be substantially complete; that is, the wastes must be modified so as not to render public water supplies objectionable for full domestic uses.

Justice to the industry as a whole also demands fairness in dealing with a few corporations which may be loath to incur the expense of, or hesitate to undertake the task of eliminating the phenolic and other objectionable waste products of industrial operations discharged into our rivers and streams.

The results in the Ohio River basin, which have been obtained by agreement and coöperation, bespeak the merit of the plan. These results have been obtained much better and more quickly than if the matter had been left, as some of our constituents would have had us do, to the enactment of federal laws and the operations of a federal enforcement agency.

We have been criticised for drawing up an instrument without legal force. Our answer is that there are enough laws already. What is needed is a "conscience" between ourselves as state agencies and between us and the industrial corporations involved. This, then, is just what we have endeavored to put into practice.

Some Aspects of Intestinal Bacteriology in Relation to Health*

LEO F. RETTGER, PH. D.

Professor of Bacteriology, Yale University, New Haven, Conn.

THE human intestine, particularly the colon, is a veritable culture tube. It is in a sense extra-corporeal, and, therefore, suffers constant invasion of an almost endless variety of microscopic organisms, bacteria, moulds and yeasts being ordinarily the most common. Yet, the environmental conditions of the intestine are such that only certain restricted groups or types are able to adapt themselves and carry on a continued existence.

It is still a moot question as to what the various influences are which operate to control the development and activities of the so-called intestinal organisms. It seems to be an established fact, however, that food and the chemical nature of the intestinal detritus play a very important part.

The contents of the intestine of the normal new-born infant are sterile. Very soon after birth microörganisms make their entrance, particularly through the mouth. According to Moro, Tissier and others there is established, in the course of relatively few hours, a heterogenous flora which is in no sense characteristic, and which is succeeded soon by one that assumes a more or less definite relationship, depending upon the nourishment of the child. When the infant is put on mother's milk the intestinal contents soon acquire the biological characteristics associated with breast feeding, the flora assuming a more or less definite picture in which Gram-positive organisms of the bifidus, acidophilus and enterococcus types play a very prominent rôle.

It was long a matter of debate between Tissier and Moro as to which of the two organisms, *B. bifidus* and *B. acidophilus*, is the more prominent. Our own researches have shown that both are present in the intestine during high lactose or dextrine feeding.[1] For example, it was repeatedly demonstrated that the administration of from 3 to 4 gm. of lactose daily to white rats results in the proliferation of the bifidus type to the almost complete exclusion of all other forms, in-

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

cluding *B. acidophilus*. On reducing the amounts of lactose fed daily from 2 to 3 gm., the bifidus type gives way to *B. acidophilus*, which can be maintained at a high percentage level by continued lactose feeding. Analogous results were obtained in human subjects.

With the gradual substitution of other foods in place of milk (lactose) there is a corresponding change in the flora, in which organisms of the bifidus and acidophilus types become relatively fewer and may be almost completely displaced by other forms, namely, those which characterize the flora of the ordinary adult living on a mixed diet which includes very little or no milk or lactose. Among these non-aciduric forms *B. coli* and *B. welchii* have a conspicuous rôle.

That the character of the intestinal flora can be altered almost at will by the regulation of the diet has been shown by us in our extensive experiments on rats and on human subjects, and by various other investigators. Lactose or dextrine, when administered in sufficient amounts, encourages the rapid development of the aciduric types of organisms in the intestine, particularly *B. acidophilus*. Other carbohydrates seem to lack this property, or possess it in only a limited degree.

For some individuals, as small amounts as from 5 to 10 gm. of lactose will suffice. Others will require 100 gm. or more daily, and occasionally a subject may not respond to less than from 350 to 400 gm. of the sugar. The range of susceptibility is indeed very wide.

Lactose is not inverted rapidly in the intestine, and thus a goodly portion of the amount taken reaches the colon where it serves as a favorable medium for the development of *B. acidophilus*. We have held, largely, on the strength of our own observations, that the stimulating effect of lactose is due to the highly favorable environment which it furnishes in the intestine for the development of *B. acidophilus*. More recently Cannon and McNease[2] claim to have shown that the change in flora is due to increased acidity alone. While increased acidity, in certain cases where the amount of lactose feeding has been at least reasonably large (as in Cannon's experiments with rats), may play a decided rôle, we still have reason to believe, from Kopeloff's[3] and our own work, that this is not the sole cause.

B. acidophilus, a characteristic organism of milk-fed infants, can be implanted in the human intestine, and by the use of proper diet made to develop and displace in a large measure the types which are so prominent in persons subsisting on the usual mixed diet, particularly *B. coli* and *B. welchii*.

Years of observations have convinced us that the most effective system of establishing the aciduric type is one in which an appropriate

strain of *B. acidophilus* is administered in large numbers along with appreciable amounts of lactose. These two important agents are combined best in a well ripened milk culture of *B. acidophilus,* now generally known throughout the country as acidophilus milk.

No one can deny certain limitations which acidophilus milk possesses for persons who have a dislike for acidified milk, or milk in any form, and particularly for those who (though rare) have no tolerance for milk proteins. A study of the situation will reveal that the permanent objectors to acidophilus milk are after all relatively few; many of those who have an initial dislike for the product can and do cultivate a taste for it. An acidophilus concentrate which combines the salient features of acidophilus milk would be a welcome substitute. From our own repeated experience with attempts to furnish such a substitute product, we are convinced that the task is extremely difficult, if not insurmountable, despite the almost innumerable efforts made in this direction, owing to the peculiarly delicate nature of *B. acidophilus,* and the exacting requirements of a genuine product.

Acidophilus milk holds a unique position here. It possesses essentially the same food value as plain milk. As a sour milk it should take a prominent place in the rapidly growing practice of supplying acid milk both as a beverage and health drink. It combines in the most satisfactory way the two chief factors upon which a successful treatment depends, namely, massive quantities of viable *B. acidophilus,* and from 4 to 5 per cent lactose, which is so essential in the stimulation and development of this organism in the intestine.

Fortunately, the casein and lactalbumin serve as pronounced buffering agents against the relatively high acidity (hydrogen ion concentration) which is produced by the organism, and which without such buffer influence would rapidly tend to destroy the viability of *B. acidophilus* and thus defeat its chief purpose. The importance of this protective action cannot be overestimated.

An endless amount of harm has been done by so-called acidophilus milk which is impure and contains relatively few organisms of the desired type. Recently manufacturers have been made to realize that this product is a major specialty and that to produce it requires unusual facilities, including a bacteriological laboratory and a trained bacteriologist, and, above all, constant scientific supervision.

From time to time we hear of renewed efforts to produce acidophilus milk in the home. The latest attempt to convince the general public of the practicability of home production is that of Rice.[4] That he does not appreciate the difficulties involved, as any trained bacteriologist would, is revealed when he states that by observing a little

care acidophilus milk may be prepared in the home; and that it is now possible to obtain a pure culture as starter at or through all drug stores. His entire method of production and of purity control rests on unsound principles of asepsis and disinfection, and if followed will lead to untold injury and disappointment. That the problem of acidophilus milk production is essentially one for the bacteriologist, and not the chemist, is again clearly shown in this instance.

It would be presumptuous for me to take advantage of this occasion to extol the virtues of acidophilus therapy. Nor do I wish to enter at this time into the subject of when and how the acidophilus principle should be applied. Such information may be had by consulting publications from our laboratory and from various other sources. Let me state briefly, however, that experiences of the past three or four years lend further support to the principle, and that our confidence in its permanent establishment has not been shaken.

It is to be regretted that often so little intelligence is exercised in applying the acidophilus treatment. In many instances it has been set up as a cure-all, and the user has been led at the outset to believe that ailments which have taken years to develop will be alleviated by one or two days' administration of this biologic agent. There has been a notion also that all ailments will respond to it.

It should be borne in mind that this treatment is indicated only in cases of intestinal disturbances and ailments associated with them, particularly constipation and diarrhea, and their concomitant systemic effects, which are not the result of anatomical or structural derangement. In all instances large quantities of the living organisms must be administered.

Prolonged treatment is necessary in some instances, particularly in cases of chronic constipation. Furthermore, even where relief has become quite apparent, continued or intermittent use of the product is highly desirable over a reasonable period of time. No well authenticated evidence has yet been brought to our knowledge that acidophilus milk has done any harm as such. To persons suffering from diabetes or who do not tolerate milk in any form, it should, of course, not be administered. In all cases of doubt, the family physician is to be consulted.

Perhaps the greatest obstacle to the full realization of acidophilus therapy lies in the multitudinous products which are parading under the name of "acidophilus," but which resemble it only in name. The market has been flooded with preparations ranging in form from tablets, water and oil suspensions, broth and tomato broth cultures and chocolate coated candies, to whey and milk cultures.

Aside from a fairly limited number of commercial milk cultures or brands of so-called acidophilus milk, very few market preparations possess any merit whatsoever as acidophilus products. This has been shown recently by James[6] in his survey of commercial *B. acidophilus* and *B. bulgaricus* cultures and preparations, and by various other scientific observers.

In relatively few instances do so-called acidophilus products contain living bacilli which resemble in any way the organism the package purports to contain. Further than this, some well known preparations contain an organism which bears a general resemblance to *B. acidophilus* but is not identical with it, and according to our observations belongs to an entirely different, but related, group of bacteria. This type of bacillus is employed, we may presume, because it is peculiarly resistant to unfavorable conditions (acidity, drying, and storage) to which *B. acidophilus* is known to have much less resistance.

California has passed a regulation which confers authority upon legally constituted agents to determine and deal with those acidophilus products dispensed within the state which are not genuine. It is hoped that other states will do likewise, and that the federal authorities will soon undertake to control the purity and genuineness of all "acidophilus" preparations sold in interstate commerce, as we have reason to believe they may do.

Finally, there is another subject that bears closely on acidophilus therapy which has recently been brought to the front; namely, the alleged etiological relation between *B. acidophilus* and dental caries. In 1922, Rodriguez[6] and McIntosh, James and Lazarus[7] reported the presence of an organism in dental decay which exhibited some of the properties of *B. acidophilus;* this they named *B. acidophilus-odontolyticus*. More recently other investigators have encountered a similar type of organism in carious teeth, and because it was regarded by them as resembling the Moro bacillus, named it *B. acidophilus*.

Bunting and Palmell[8] unequivocally announced the organism to which they ascribed a definite and direct etiological relationship in dental caries as *B. acidophilus*. Since then Bunting and his associates have made similar statements. We believe that their classification was not based on sufficient scientific evidence, and that they, therefore, violated a very important principle of taxonomy. That the biological position of their organism was of relatively little concern to them, although they expressed such certainty as to its identity, cannot but impress itself on the minds of those who have followed their work and printed statements.

The extensive researches conducted in our laboratory by Mori-

shita,[9] on more than 100 different strains of acid-forming and aciduric organisms isolated from dental caries, together with some of Bunting's strains, have conclusively shown that the aciduric organisms commonly associated with abnormal, decaying teeth are not *B. acidophilus*, but rather distantly related types. Among other things, he states, in his preliminary publication, that "the occurrence of *B. acidophilus* of the intestinal type in dental caries is relatively rare compared with the other aciduric organisms found, and may be regarded as merely adventitious"; and, "the present comparative study seems to the writer to warrant the conclusion that the tooth organisms discussed (by him) constitute a type entirely separate from *B. acidophilus* of the intestinal tract."

Space does not permit me to go into the various points of difference upon which Dr. Morishita based his conclusions.

Cuba's First National Congress of the Child

THE first National Congress of the Child in Cuba was held in Habana in December, 1928, under the auspices of the government.

The resolutions enacted called for, among other things, the establishment of juvenile courts, courses in dietetics for teachers of primary schools, legislation for prenuptial certificates of health, the appointment of a committee of experts for the study of infant and child feeding, medical supervision over school children, and a number of other child welfare measures.

The congress has also adopted a statement of principles on the rights of the child, called the Declaration of Habana. This is somewhat similar to the Declaration of Geneva on the same subject.

Evaporated Milk and Its Relation to Public Health*

FRANK E. RICE, PH. D.

Executive Secretary, Evaporated Milk Association, Chicago, Ill.

THE use of concentrated and preserved milks has grown tremendously in the past 20 years. In 1908 the amount of milk evaporated, condensed and dried, and consumed in the United States was less than a billion pounds. Now 4⅓ billion pounds per annum is used.

Evaporated milk is prepared by removing a little over half the water, sealing in cans, and sterilizing. It has a creamy consistence and differs from ordinary milk in containing slightly more than twice the amount of solids. The United States Government sets a minimum standard of 7.8 per cent fat and 25.5 per cent total milk solids.

Condensed milk, sometimes called " sweetened condensed milk," is concentrated to about the same degree as evaporated milk, and sufficient sugar added to preserve it.

Dry milk is a powder, and contains not more than 1 or 2 per cent of moisture. It contains no added substance, but often a part or all of the cream is removed. If skimmed, or part skimmed, the label so states.

Evaporated milk, in this country, is not skimmed. Sweetened condensed skimmed milk in cans has appeared from time to time, but most of that now sold in the United States is whole milk, though sweetened condensed skimmed milk in barrels is a common commodity, used in candy and ice cream making.

There are two other forms of concentrated milk of less importance to us here—one sold in bulk, not sterilized, which goes mostly to ice cream manufacturers, and *malted milk,* which contains predominantly products resulting from the malting of grain, only about a third of the total being milk solids.

EVAPORATED MILK

On the basis of milk solids, more unsweetened evaporated milk is consumed in the United States than condensed and dry together

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

—nearly twice as much. As many pounds are used as ice cream, twice as many as candy. The industry takes the production of 600,000 cows. Thirty-eight thousand freight cars were required to carry last year's pack.

This would seem to be a commodity that deserves attention from the public health point of view. First, as a milk supply, is it pure, clean and wholesome? Second, is it a nutritious, economical and practical food, one that can be recommended for greater use as a means of promoting the health of a family, a community, and a nation?

Evaporated milk plants are located near the source of supply. In a few hours after the raw milk is produced it has been hauled to the plant and transformed into evaporated milk. It usually takes longer to transport raw milk to the large city and deliver it. For this reason it has been said that evaporated milk reaches the consumer in fresher condition. If " freshness " in foods means that they have not undergone changes brought about by bacteria or enzymes, then canned foods in general can be considered to be the freshest.

Water is removed by heating *in vacuo,* and the concentrated milk is homogenized by forcing it under high pressure through a minute aperture. This reduces the fat globules to a small fraction of their original size. In fact colloidal proportions are attained, since the particles remain distributed throughout the milk, uninfluenced by gravity. Cream does not separate in evaporated milk.

The cans are filled, sealed and sterilized under a steam pressure of about 11 pounds.

SAFETY

Good evaporated milk cannot be prepared from dirty or sour milk. Every packer exercises supervision over the dairies which produce the milk, and its quality is observed when brought to the plant. The farmer must employ sanitary methods, and keep the milk cold until delivered.

The milk within the plant passes rapidly from one stage to the next through an arterial system of sanitary piping, " not touched by human hands."

Sterilization in the can frees the milk of any organisms that could impair its quality or endanger health. As far as the transmission of disease is concerned, evaporated milk gives even more protection than certified milk because the hazard of human error is eliminated.

The answer to the first question is in the affirmative—evaporated milk is safe and dependable.

The transportation of food from the place of production to the

place of consumption, and its storage from the season of plenty to the season of scarcity, are problems of major importance. Economy and safety, chiefly, are involved in the former and the prevention of waste in the latter.

Some maintain that the milk supply of the future will be preserved in cans. This will probably never be wholly true, but it will be a more important factor than at present. The milk shed of the city is constantly widening. There must be a limit, a distance beyond which it is neither economical nor safe to ship raw milk to the consumer. The cost of shipping 7 parts of water with 1 part of food, and of handling such an extremely perishable food, cannot but take its toll in limited consumption.

There are plenty of data to prove that the evaporated milk industry is fulfilling the requirements of an economical milk supply. Evaporated milk produced within 100 miles of Chicago is being delivered in that city for 20 per cent less than the milk delivered in bottles. Indeed, Wisconsin milk is delivered in Florida for much less than the cost of market milk in that state. By 43 years of scientific effort, the industry has learned how to evaporate milk efficiently and economically; refrigeration of the product in transit is not necessary; there is less water to transport; no bottles to break; no high wages to pay to union milk wagon drivers.

Evaporated milk production acts as a stabilizer of the whole dairy industry. It continues throughout the year, but the peak comes at the height of the milk flow. At this time, when there is a raw milk surplus, waste would occur, and it is likely that the farmer would receive a ruinous price were it not possible to transform the surplus into such less perishable products as evaporated milk, butter and cheese.

HOME ECONOMICS

If we agree that it would be for the betterment of the public health to increase milk consumption, it would seem to be wise, as one part of our educational program, to find new ways of putting milk into the diet, rather than to expend all our efforts in urging the drinking of more milk. There is a limit to the amount of milk people will drink; a quart per person per day probably can never be reached.

Many cooked foods require milk, and many could be made more appetizing as well as more nourishing by the inclusion of milk. Evaporated milk is particularly well adapted for this.

Nutritional workers have long maintained that ice cream would be a better food if it contained more of all the solids of whole milk and less fat than the government requires. Ice cream is consumed

more largely in summer and in warm climates where foods of high caloric value are undesirable. It is frequently taken as a dessert after an entirely adequate meal. A low fat ice cream with fine texture can be made from evaporated milk. Due to the physical character of the fat and protein only small ice crystals are permitted to form in freezing. Ice cream and candy manufacturers have long recognized the influence of evaporated milk on texture.

For artificial feeding of infants it is necessary to have milk that is safe, digestible, uniform, and nutritious. Evaporated milk fulfils these qualifications. The curd is soft, resembling that of human milk, because of the physical changes in the casein due to homogenizing and sterilizing.

NUTRITIVE VALUE

The statement has often been made that when milk is heated there is some loss of mineral. A slight precipitation on the sides of the container has been noted where large quantities of milk are heated. From the point of view of colloid chemistry, there is some evidence of a rearrangement of mineral combinations in milk when heated. There is no evidence that the new combination of calcium, phosphorus and other elements is not just as soluble in the gastric juice and just as assimilable as the original combination. It has been demonstrated that the calcium and phosphorus of evaporated milk are fully assimilable.

With the exception of C, the vitamins are present in apparently the same amounts as in raw milk. Not only does the casein of evaporated milk form a more fluid curd, but it is more readily hydrolyzed by the digestive enzymes, and assimilated.

The fat is more highly emulsified in consequence of the homogenization. Since emulsification is the first step in fat digestion, evaporated milk should prove particularly acceptable to infants or those with deranged digestive functions.

There is evidence that an individual who reacts anaphylactically to raw milk may take foods containing evaporated milk with impunity. The heat of sterilization apparently renders the sensitizing constituents of the milk inactive.

A dietetic experiment of magnitude proving the value of the concentrated milks in public health was the work of the American Relief Administration in Europe during the World War. Herbert Hoover in an address before the World's Dairy Congress made the following statement:

> It is perhaps interesting to note that this organization and its allied organizations exported from the United States, for the use of those children, upwards of

500 millions of pounds of condensed (evaporated and condensed) milk during the period of the war and reconstruction. It could be very well said that the saving of millions of children was accomplished only by virtue of the strength, the resilience, of the American Dairy Industry.

SUMMARY AND CONCLUSIONS

The marked increase in the use of the concentrated milks indicates their importance from the public health point of view. One and one-quarter billion pounds per year of unsweetened evaporated milk is consumed in our country.

Canned foods of all kinds have received a clean bill of health. The methods of production are above reproach, and any loss in nutritive value in canning is negligible.

The preparation of evaporated milk from good, clean milk near the source of production, and the promptness with which it is evaporated, are among the factors that make it the safest supply. From the economic point of view, evaporated milk is the most efficient, and this industry assists in stabilizing the whole dairy industry.

The average consumption of whole milk cannot be brought to the optimum by alone urging the drinking of milk. The use of milk in prepared foods can be made a more important factor than it is now. Evaporated milk is the logical whole milk supply. Its concentration, smoothness and flavor admirably adapt it to this purpose. Its convenience makes for increased usage.

Infants require a safe, digestible, uniform and nutritious milk—qualities found in evaporated milk.

There is no important loss in nutritive value when raw milk is evaporated. The protein and fat are made more digestible.

The public health value of evaporated, and other concentrated milks, was fully demonstrated during the World War.

Evaporated milk is no longer to be recommended only when raw milk is not to be had. It has a definite place in the nutritional economy of the family and the nation.

NOTE: The references presented with this paper may be obtained by corresponding with Dr. Rice.

DISCUSSION

McKIM MARRIOTT, M. D.

Dean, Washington University Medical School, St. Louis, Mo.

FROM the theoretical standpoint, evaporated milk would appear to possess distinct advantages for infant feeding. Chief among these are absolute sterility, easy digestibility on account of the heat alteration of protein, constant and known composition, and availability, and the ease with which feeding formulas

may be prepared. It is difficult to see why it has not had a more extensive use for this purpose. The prejudice against canned foods, and confusion with sweetened, condensed milk, seem to have been the important factors in limiting its use. It has been recommended by some pediatricians for use in the treatment of infants with special conditions, but has not been generally advocated as a routine food for normal infants. Fresh milk has apparently been considered superior, but no good reasons for this have been brought forward.

Evaporated milk possesses so many advantages that it seemed desirable to determine, by a practical test, whether it possesses any disadvantages, and whether it can safely and advantageously be substituted for fresh milk in the routine feeding of infants.

During the past 15 months we have fed 668 infants on formulas prepared from evaporated milk, the composition of the final product being, in each instance, approximately the same as the individual would have been receiving had fresh milk been used. The length of time the formulas were fed varied from 2 weeks to 1 year, the average being 3½ months. In the majority of normal infants, feeding with evaporated milk was started during the first week of life. In addition, there were included 75 sick infants in a hospital service and out-patient department. These were suffering from a variety of conditions, including undernutrition, diarrhea, pyloric stenosis and various infections. Seven premature infants weighing from 1 to 5 pounds received evaporated milk as the exclusive food. The 668 infants were compared with 658 observed at the same time who received fresh cow's milk mixtures, or were exclusively breast fed, who came within approximately the same age limits, and included approximately the same distribution between normal infants and those suffering from various diseases.

Of the newly-born, 80 per cent regained the birth weight by the end of 14 day, as compared with 66 per cent in the control series. Of the normal infants followed for a period of months, the average gain in weight was 23.4 grams per day, as compared with 25.5 grams in the control series. The weight of those fed on evaporated milk at the end of the period of observation averaged 100.4 per cent of the theoretical normal weight for the respective ages, although the average weight at the time the feeding was begun was but 96.3 per cent of the theoretical, these figures being based upon the average weight of breast fed babies.

Of the hospital cases, which included all of the more seriously ill and difficult feeding problems, the average gain in weight was 18.5 grams per day as compared with 17.4 in the controls. There was no evidence that the development of those fed on evaporated milk was retarded. Dentition, sitting and walking occurred at the average normal time. There was no evidence of lack of resistance to infection. Although the observations extended over two summers, it was noteworthy that the infants fed on evaporated milk were, as a group, not subject to fermentative diarrheas. One of these developed eczema and two in the control series. Infants fed on evaporated milk for long periods were examined clinically and radiologically for evidence of rickets and none was found, nor was there any clinical evidence of scurvy. It should be noted that all received daily doses of cod liver oil and orange juice.

In addition to our own observations, a questionnaire was sent to a group of physicians who had been graduate students in our clinic, most of whom were practicing in rural districts, inquiring as to their experiences with the use of evaporated milk in the feeding of infants. To date no unfavorable replies have been received. A number of them have used evaporated milk almost exclusively.

Some stated that they considered it superior to fresh milk in most cases for well babies, and in all cases for the sick. Others commented on its superiority for use in rural districts, and among the poor who could not obtain suitable fresh milk, or did not have proper refrigeration. Some stated that they rarely saw the patients again after putting them on evaporated milk, as they did not thereafter suffer from feeding difficulties.

From this study it may be concluded that evaporated milk not only has no disadvantages but has considerable advantages over fresh milk for the feeding of both normal and sick infants.

Housing Betterment

THE Pennsylvania Legislature, which has just closed its session, worked for and against housing betterment, says the Philadelphia Housing Association.

Its contribution to housing progress is the Woodward Zoning Bill, introduced by Senator George S. Woodward, which, after a rather disheartening experience, passed the House and was signed by Governor John S. Fisher.

The Woodward Bill, which gives Philadelphia permission to adopt a zoning ordinance, will stand comparison with the zoning enabling acts on the statute books of over 30 states. It is modeled after and is practically a duplicate of the Standard State Zoning Enabling Act of the U. S. Department of Commerce. In addition, it authorizes a bureau of zoning, establishes penalties, and contains a validity section to care for adverse court decisions, if such should be rendered against any of its provisions. In signing this bill Governor Fisher has given Philadelphia the most far-reaching legislation of beneficial character which has passed the General Assembly in many years.

Prior to this action of the Governor, the City Council of Philadelphia, at the request of the Mayor, passed a resolution endorsing the Woodward Bill, and three Councilmen appeared at the hearing in Harrisburg and requested the enactment of the bill into law. Moreover, while this authority was being granted by the State Legislature, the councilmanic body enacted a companion piece of legislation creating a city planning commission. The agitation for this commission was begun some months ago by local organizations which persuaded the Mayor to call together 300 citizens to advise on the plans and scope of a planning commission. Following the enthusiastic reception of the proposal, Mayor Mackey prepared and sent to City Council an ordinance creating a committee of 15 members, which the Council passed in record time.

The outlook for the passage of a zoning ordinance and the appointment of a city planning commission for Philadelphia is most gratifying today. To all appearances, the efforts of the Housing Association for many years to further these two projects are about to reach fruition.

ANOTHER ARGUMENT FOR PASTEURIZATION

SEPTIC sore throat was introduced to us in America, so to speak, by Boston, Brookline and Cambridge, in the spring of 1911, and since that time, recurring epidemics have taken a heavy toll of raw milk users. In spite of the various publications on the subject and the teaching of milk experts and sanitarians generally, we cannot escape the conclusion that the disease is too little considered, and that even health officers are not as much awake to the necessities of the case as they should be, though we express this opinion with full sympathy for the legal and technical difficulties which confront many of them in their official work.

The latest epidemic to attract wide attention occurred in Lee, Mass., in June and July, 1928. Lee is a town of 4,000 inhabitants. Within approximately 2 weeks, 950 people suffered from septic sore throat, and 48 died as a result. The outbreak was carefully studied epidemiologically and bacteriologically, so that we have an exact and clear account of it. A recent number of the *New England Journal of Medicine*[1] devotes considerable space to the matter, and gives as well an admirable historical review of the disease, going back as far as authentic accounts can be found. More than 60 epidemics have been recorded, involving more than 30,000 cases. From 1911 to 1928, inclusive, there have been in Massachusetts alone, 1,468 cases of typhoid fever, 74 of diphtheria, 1,147 of scarlet fever, and 3,986 of septic sore throat, attributed to milk as the carrier. During the same period, there have been only 369 cases of water-borne typhoid fever.

We cannot do better than to emphasize the points made by Bigelow and White,[1] who point out that in spite of our knowledge and insistence on protection of water supplies, our attempts at enforcing sanitary laws in regard to milk often meet with discouragement and

lack of sympathy on the part of consumers, and with distinct opposition on the part of producers and distributors.

Septic sore throat is due to a hemolytic streptococcus, usually of the *epidemicus* type, and is practically exclusively a milk-borne disease. Fortunately the streptococcus is comparatively easily killed by heat, so that even ordinary pasteurization will render a milk supply safe.

Among other important features brought out in the investigation of the Lee epidemic, two are of especially practical value—the apparent responsibility of a single cow, and the fact that an infected quarter may not show gross lesions, and produce milk of apparently normal character. One cow in an otherwise healthy herd showed distinct disease in the left front quarter, the milk from which had been excluded. However, the hind quarter on the same side, though apparently healthy, and giving milk of apparently good quality, was found to contain great numbers of the *S. epidemicus*. The animal was kept under observation for 2 months, during which time samples of milk were frequently examined. The two right quarters remained normal in appearance and negative for *S. epidemicus*. We must recognize that dairymen not infrequently use the milk from one or more quarters of a diseased udder.

Our only protection at present against this, as well as against other milk-borne diseases, is proper pasteurization. Once again, we wish to insist that with the exception of certified milk, all market milk should be pasteurized. In this lies our only safety against milk-borne diseases.

A PUBLIC HEALTH AWARD AT TULANE UNIVERSITY

THERE has been established at Tulane University, New Orleans, La., an award to be known as the " Geiger Medal," to be granted yearly to that student of the university, either senior or graduate, who prepares the best thesis on some phase of public health of particular interest to the southern states or countries contiguous to them.

The medal has been accepted by the Board of Administrators through President Dinwiddie. For the present session, the award will be made by a committee consisting of the head of the Department of English in the College of Arts and Sciences as chairman, the Dean of the School of Medicine, Professors Musser and Faust of the School of

Medicine, and Professor E. S. Hathaway of the College of Arts and Sciences.

We cannot but rejoice at this recognition of public health by our leading southern university.

The medal is named in honor of Dr. J. C. Geiger, at present Associate Professor of Epidemiology in the Medical School of the University of California. Dr. Geiger is well known for his epidemiological studies in connection with the work on botulism done by the U. S. Public Health Service with the Departments of Hygiene of the University of Chicago and the University of California. He was Assistant Health Commissioner of the City of Chicago, and was one of those who, to all intents and purposes, was dropped by Mayor Thompson.

THE THIRD CONFERENCE ON PUBLIC HEALTH

THE Third Annual Conference on Public Health, called by the American Medical Association, met in Chicago, Ill., March 29 and 30. The first day was devoted to a discussion of coöperation between official and voluntary health agencies and the medical profession, in the promotion of public health. This program was outlined by the committee appointed by the 1928 Conference.

The second day the work of the Hygienic Laboratory, especially research, was described, followed by a review of our knowledge of undulant fever and its relation to public health.

It will be remembered that much of the 1928 meeting was devoted to a somewhat heated discussion of the differences which had arisen over the conduct of a demonstration, some physicians believing themselves to be adversely affected. The meeting ended, however, with a sincere attempt on the part of all to reach an understanding, and to establish friendly relations. The 1929 meeting was largely devoted to furthering this same object.

There can be little doubt that some voluntary agencies have in the past blundered. They have invaded fields which have for many years been in the hands of physicians, and have not always been tactful, nor have they always brought to their aid the best medical advice. The resident physicians, and to some extent the medical profession in general, have resented these invasions. Irritation and opposition have developed which could almost certainly have been avoided by the exercise of tact and judgment—in other words, application of ethics.

The medical profession has for years recognized and welcomed public health work in the control of water and milk supplies, sewage

disposal, and even vaccination against smallpox. With the increasing number of diseases which can be prevented by immunization, a new factor has entered, in which the treatment of the individual, which has been a medical function, has been invaded. During these campaigns by voluntary agencies, much of the propaganda work has been done by nurses and others, perhaps physicians, brought in from the outside. There can be no doubt that the opposition of local physicians is based largely upon what they consider outside interference, though in some cases there is fear of having their means of living taken away from them by the prevention of disease.

Some foundations have recognized that their demonstrations have led the public to expect immunization free or at a minimum cost. When the campaign is over, the public is left high and dry, as far as the foundation is concerned, and must pay for further work, unless, as is sometimes the case, official health agencies take it over.

We believe that the more education there is along the lines of public health and preventive medicine, the more work the physician of the community will have to do, though there may be a period of readjustment, during which the private physician suffers.

A similar controversy arose over the establishment of official public health laboratories, those conducting private laboratories feeling that their work would be taken away from them. We do not pretend to have made an exhaustive survey of this matter, but many observations have convinced us that private laboratories are more numerous and doing a greater amount of work than ever before, and cannot escape the conviction that the official laboratories have trained the public to demand such service.

Essentially the same factors are involved in the relation between voluntary agencies and private physicians. If a voluntary or even an official agency sends bumptious men and women into the field, trouble will inevitably result. On the other hand, it has been abundantly proved that where tact is shown, physicians, with the exception of a few unfortunate characters always to be found, are willing and eager to coöperate and to acquire the newer knowledge. In this connection, we wish we could give the experiences of a certain foundation which has avoided the errors discussed.

The voluntary agency and the foundation are here to stay, whether we like it or not. Many of them are in the hands of non-medical executives, some of whom have judgment and tact, while some are devoid of these necessary qualities. Some are capable of learning, some apparently are not. We are strong in our belief that a working basis will be found, and that cordial relations will be established, not

only between voluntary and official health agencies, but between them and the medical profession. As well put, in one of the papers at the conference:

> The voluntary agency can best meet its responsibility by stimulating the individual citizen to insist upon a modern health service from his physician, by helping the physician to enlarge his scope of service and render a better service, and by helping the official agency to a stronger and more secure place in the governmental scheme.

It was finally agreed, on motion, that the chairman be requested to appoint a committee to consider the papers presented, and to draft such suggestions as might seem desirable for consideration at the next conference, all carrying the general idea of coöperation.

A NEW ASSOCIATION

ONE is always inclined to groan over the formation of a new society. Already the professional man is burdened with the number to which he belongs or should belong. It is impossible to attend all of the meetings, and difficult to keep up with the literature put out by the various societies; yet now and then there seems to be a real need for a new one, and this has been recognized by the foundation of the American Mouth Health Association, incorporated in Minnesota.

The avowed purposes of the association are to inform the public of the importance of mouth hygiene; to establish a central bureau of mouth health education with local branches throughout the country; to promote the teaching of healthful living, with especial reference to the mouth and teeth; and to give support to other health and welfare agencies.

An advisory board has been appointed, the first meeting of which was held in Rochester, Minn., May 17 and 18, where the prospectus of the association was discussed, stock taken, and outlines for the future tentatively determined. Some extremely interesting studies made at the Mayo Clinic were presented, illustrated with photographs, and the members were given the opportunity of seeing the experimental animals.

The importance of oral hygiene is being more and more recognized. It was regarded for a long time as a specialty in which only the dentist was interested, and his work was considered to lie largely in the correction of defects and repair of damage already done. The influence of the teeth and the mouth on the general health has not been recognized until comparatively recently, and even now its significance is not fully understood, though an imposing number of organic as well as functional derangements are known to have their

origin in, or to be adversely influenced by, infections of the gums, teeth or tonsils. With the study of focal infections there came a veritable orgy of tooth pulling, against which there is now a revulsion of feeling, though physicians are still referring cases to dentists more than formerly, and remarkable restorations to health follow the correction of defects and the removal of focuses of infection.

It was to be expected that the teeth would not escape attention in the intensive study of vitamins which has been going on. This in turn has brought a renewal of our interest in foods and diets in general.

We cannot but feel that there is an open field for this new association, and wish it great success. There is certainly something wrong with our habits when the vast majority of people—young and old—suffer from defective teeth and a train of disorders resulting therefrom. Our teeth have not kept pace with our changes in occupation and methods of living. We have perhaps become too much civilized. We live in an age of prepared and packaged foods, pre-chewed and often pre-digested. Will not a return to nature improve matters? The Sybarites disappeared from the world.

SAMUEL H. GILLILAND, V. M. D., M. D.

THE death of Dr. Samuel H. Gilliland on May 27, at the age of 51, removes a notable figure from the biological manufacturing world.

For many years he was associated with the late Dr. Leonard Pearson in the work of the State Live Stock Sanitary Board of Pennsylvania, and held a number of offices requiring expert knowledge as well as great executive ability, all of which he filled with credit to himself and advantage to those whom he served. He held the degrees of Doctor of Veterinary Medicine and Doctor of Medicine, both obtained from the University of Pennsylvania while he was carrying on his work in the laboratory of the State Live Stock Sanitary Board. He had made several trips to Europe for the purpose of study.

In Pennsylvania he held successively the offices of Director of the Laboratory of the State Live Stock Sanitary Board, Director of the Laboratories of the State Board of Health, and State Veterinarian. During the World War he was Director of the Laboratory for the training of veterinarians situated at the University of Pennsylvania, holding the commission of Major in the Medical Corps of the U. S. Army. Here veterinarians studied not only the contagious diseases of animals, but also serology and laboratory diagnostic work.

Dr. Gilliland was one of the pioneers in the study of immunity against tuberculosis, and, with the late Dr. Leonard Pearson, published, in 1902, " Some Experiments upon the Immunization of Cattle

against Tuberculosis." While similar work had been done before, we believe this was the first in the world which was carefully controlled by post-mortem observation and microscopical examination of the tissues. Subsequently Dr. Gilliland published several articles under his own name on the same subject. He also carried out extensive immunization experiments on some farms breeding only the highest class of cattle for the production of certified milk.

Dr. Gilliland was a member of our Association, and a Fellow; a member of the American Medical Association; Philadelphia Pathological Society; Philadelphia County Medical Society; University Club; Medical Club; National Tuberculosis Association; American Veterinary Medical Association; and the United States Live Stock Sanitary Association.

PROPOSED ENTERTAINMENTS AND TRIPS IN MINNEAPOLIS

Drive through Lake district to Glen Lake Sanatorium. Inspection. Buffet luncheon at Sanatorium (2¼ hours)

Dedication Exercises
University Public Health Pavilion
Luncheon (5 hours)

Drive to University Main Campus and Agricultural Campus (2½ hours)

Trip to Hospitals and Institutions for care and rehabilitation of the handicapped (4 hours)
- a. Michael Dowling School
- b. Minnesota Hospital for Crippled Children
- c. Shrine Hospital for Crippled Children
- d. Arthur J. Gillette State Hospital for Crippled Children

Visit through Social Service and Health Agencies (2 hours)
- a. Citizens' Aid Building
- b. Minneapolis Division of Health
- c. Lymanhurst School and Clinic
- d. Minneapolis General Hospital

Visit to the University Medical School, University Hospitals (2 hours)
- a. Cancer Institute
- b. Todd Memorial Clinic
- c. Institute of Child Welfare

Trip to the Water Purification Plants at Fridley Park and Columbia Heights (3 hours)

Trip to the Milk Producing, Pasteurizing, and Distributing Plants (3 hours)
- a. Franklin Co-Operative Creameries
- b. Hockney Dairy Farm, etc.

Trip to the Minneapolis Flour Mills (2 hours)
- a. Inspection of Food Products
- b. Luncheon

For visiting ladies
(Two alternative drives, 2 and 3 hours respectively)
Drive around the lakes and boulevards surrounding the city (a. or b.)
- a. Tea at Minneapolis Art Institute
- b. Tea at Woman's Club

Special Trip to the Mayo Clinic and the Mayo Foundation, Rochester, Minn., fast Railway service
- a. Research Health Clinic
- b. Luncheon

Opening Session—Monday, September 30, 8:00 P.M.—Nicollet Hotel
- a. Program
- b. General Reception
- c. Dance

Banquet—Thursday, October 3, 7:00 P.M.—Nicollet Hotel
- a. After dinner program
- b. Dance

A possible trip to the St. Paul Hospitals and Institutions (3 hours)

PRELIMINARY PROGRAM OF THE FIFTY-EIGHTH ANNUAL MEETING

AMERICAN PUBLIC HEALTH ASSOCIATION

Minneapolis, Minn., September 30–October 5, 1929

DELEGATES are urged to consult the Final Program, at the meeting, for information as to the exact time and place of sessions. The General Sessions will be held at the Hotel Nicollet. Section and other meetings will be held in the Municipal Auditorium. Morning sessions will be at 9:30; luncheon sessions at 12:30; afternoon sessions at 2:30; dinner sessions at 6:30; and evening sessions at 8:00.

General Sessions

First Session—Monday Evening

Addresses of Welcome

Address of the President of the American Public Health Association. George W. Fuller, Fuller & McClintock, New York, N. Y.

Address of the President or a Representative of the American Child Health Association.

Reception and Dancing

Banquet—Thursday Evening

No Title. George E. Vincent, Ph.D., President, The Rockefeller Foundation, New York, N. Y.

Dancing

Joint Sessions

CHILD HYGIENE SECTION AND AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

First Session—Monday Afternoon

The Rôle of the School Physician in a School Health Program. Charles H. Keene, M.D., Professor of Hygiene, University of Buffalo, Buffalo, N. Y.

Report of the Committee on Sickness Absence Records. *Chairman*, Don W. Gudakunst, M.D., Director, School Health Service, Health Department, Detroit, Mich.

The Value of a Survey of Senior Grades in Primary Schools in an Attempt to Evaluate the Present School Health Service. J. E. Davey, M.D., Chief School Medical Officer, Hamilton, Ont.

Training for School Health Workers. Sven R. Lokrantz, M.D., Medical Director, Los Angeles City Schools, Los Angeles, Calif.

Second Session—Tuesday Afternoon

School Health Work. How It May Be Improved. JOHN L. C. COFFIN, M.D., School Physician, Los Angeles City Schools, Los Angeles, Calif.

A Practicable Program of School Health Supervision in Secondary Schools. CHARLES H. KEENE, M.D., Professor of Hygiene, University of Buffalo, Buffalo, N. Y.

Suggested Measures for Increasing the Coöperation between the Family Physician, the Parent and School Health Staff. MARY E. CRAWFORD, M.D., Chief School Medical Officer, Winnipeg, Man.

Recording of Medical Examinations of School Children Leading to Credits. FRANCIS E. HARRINGTON, M.D., Commissioner of Health, Minneapolis, Minn.

CHILD HYGIENE AND PUBLIC HEALTH EDUCATION SECTIONS

First Session—Thursday Afternoon

Health Teaching in the Elementary Schools. IDA M. HASKINS, Director of Health Education, Public Schools, Mansfield, O.

The Rôle of the Classroom Teacher in a School Health Education Program. ANNE L. WHITNEY, Director of Health Education, American Child Health Association, New York, N. Y.

Training of Teachers for Health Education Work. ELMA ROOD, Director of Nursing, Peabody College for Teachers, Nashville, Tenn.

Second Session—Friday Afternoon

The Rôle of a School Superintendent in a School Health Program. R. G. JONES, Superintendent of Schools, Cleveland, O.

Discussion

Procedures for Inter-relating Health Teaching and Health Administration. WILLIAM DEKLEINE, M.D., American Red Cross, Washington, D. C.

Discussion

CHILD HYGIENE AND PUBLIC HEALTH NURSING SECTIONS

Friday Morning

Community-Wide Child Hygiene Program Including Official and Non-Official Health Agencies and the Medical Profession. MARY RIGGS NOBLE, M.D., Chief Preschool Division, Bureau of Child Health, State Department of Health, Harrisburg, Pa.

The Nurse's Message of Child Health to the Family and How She Can Get It Across under Varying Conditions. HELEN C. PECK, R.N., Executive Secretary, Infant Welfare Society, Minneapolis, Minn.

Discussion

How Can the Nurse Help the Health Officer to Get His Message Across?

From the Standpoint of the City—HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich.

From the Standpoint of the County—H. S. MUSTARD, M.D., Assistant to the Commissioner, State Department of Health, Nashville, Tenn.

Elements in the Home Controlling Infant Welfare Activity. AMELIA GRANT, R.N., Director, Bureau of Nursing, Department of Health, New York, N. Y.

FOOD, DRUGS AND NUTRITION AND PUBLIC HEALTH ENGINEERING SECTIONS

Thursday Afternoon

Low Per Capita Milk Consumption—A National Nutritional Problem. R. S. CRAIG, Director, Bureau of Chemistry and Food, City Health Department, Baltimore, Md.

The Significance of Thermophilic Bacteria in Market Milk. L. A. ROGERS, D.Sc., In Charge, Research Laboratories, Bureau of Dairy Industry, U. S. Department of Agriculture, Washington, D. C.

Discussion. HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich.

Results Achieved by a State-Wide Milk Sanitation Program. E. L. BISHOP, M.D., State Health Commissioner, and W. H. HASKELL, In Charge, Milk Sanitation, State Department of Health, Nashville, Tenn.

Discussion

A Practical Definition of Pasteurization. LESLIE C. FRANK, Sanitary Engineer in Charge, Milk Investigations, U. S. Public Health Service, Montgomery, Ala.

Discussion. GEORGE W. GRIM, V.M.D., Milk Control Officer, Ardmore, Pa.

LABORATORY AND EPIDEMIOLOGY SECTIONS

Friday Afternoon

The Common Cold, and How It Is Being Studied Epidemiologically. W. H. FROST, M.D., Johns Hopkins University, Baltimore, Md.

Field Studies in Respiratory Infections. WILSON G. SMILLIE, M.D., School of Public Health, Harvard University, Boston, Mass.

Bacteriological Findings in Pneumonia and Their Bearing on Epidemiology. WILLIAM H. PARK, M.D., Director of Laboratories, Department of Health, New York, N. Y.

HEALTH OFFICERS AND EPIDEMIOLOGY SECTIONS

Wednesday Afternoon

Opportunity and Status of Epidemiological Service in State and City Health Departments. JOHN A. FERRELL, M.D., International Health Board, New York, N. Y.

Practice and Results of the Epidemiological Work of the State Department of Health of California. W. H. KELLOGG, M.D., or JOHN N. FORCE, M.D., University of California, Berkeley, Calif.

Milk-Borne Septic Sore Throat and Scarlet Fever. CLARENCE L. SCAMMAN, M.D., Assistant State Commissioner of Health, Newtonville, Mass.

PUBLIC HEALTH ENGINEERING AND LABORATORY SECTIONS

Thursday Morning

The Use of Synthetic Dilution Waters for Bacteriological and Oxygen Demand Determinations. E. J. THERIAULT and C. T. BUTTERFIELD, Stream Pollution Investigations Station, U. S. Public Health Service, Cincinnati, O.

The Treatment of Creamery Wastes. L. F. WARRICK, State Sanitary Engineer, State Board of Health, Madison, Wis. (*Stereopticon Illustration.*)

Administrative Control of Waterways Pollution. W. L. STEVENSON, Chief Engineer, State Department of Health, Harrisburg, Pa.

The Administrative Significance of Proposed Changes in Standard Methods of Water Analyses. JOHN F. NORTON, PH.D., Director of Laboratories, Department of Health, Detroit, Mich.

Discussion. J. J. HINMAN, JR., University of Iowa, Iowa City, Ia., and ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md.

PUBLIC HEALTH ENGINEERING AND CONFERENCE OF STATE SANITARY ENGINEERS

Dinner Session—Tuesday Evening

SECTION SESSIONS

LABORATORY

First Session—Tuesday Morning

The Streptococcus of Septic Sore Throat. WILLIAM D. FROST, M.D., R. C. THOMAS, MILDRED GUMM and MYRTLE SHAW, University of Wisconsin, Madison, Wis.

The Opsonic Method for Identification of Scarlet Fever Streptococci—Its Applicability for the Detection of Carriers. RUTH TUNNICLIFF, M.D., Chicago, Ill.

Anti-Streptococcus Serum in Scarlet Fever. A. B. WADSWORTH, M.D., State Department of Health Laboratory, Albany, N. Y.

The Relationships of the Hemolytic Streptococci Causing Erysipelas. ANNA W. WILLIAMS, M.D., Research Laboratory, Department of Health, New York, N. Y.

Meningitis. JOHN F. NORTON, PH.D., Director of Laboratories, Department of Health, Detroit, Mich.

Second Session—Wednesday Morning

Report of the Committee on Training and Personnel. THOMAS G. HULL, PH.D., State Department of Health, Springfield, Ill.

Standardization of the Wassermann Test. RUTH GILBERT, M.D., Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Report of the Committee on Standard Methods. *Chairman,* EDWIN O. JORDAN, PH.D., University of Chicago, Chicago, Ill.

Report of the Committee on Abstracts in the Journal. *Chairman,* C. C. YOUNG, D.P.H., Department of Health Laboratory, Lansing, Mich.

Report of the Committee to Confer with the Association Committee on Dairy Products. *Chairman,* ROBERT S. BREED, PH.D., New York Agricultural Experiment Station, Geneva, N. Y.

Mediterranean Fever as Observed in the Mediterranean Countries. I. FOREST HUDDLESON, D.V.M., Michigan State College, East Lansing, Mich.

Tularemia. R. G. GREEN, M.D., and E. M. WADE, State Board of Health, Minneapolis, Minn.

The Study of Cultures of Monilia Isolated from Sputum. RUTH GILBERT, M.D., and W. M. GROESBECK, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

The Sanitary Significance of Thermophilic Bacteria in Milk. ROBERT S. BREED, PH.D., New York Agricultural Experiment Station, Geneva, N. Y.

The Applicability of the Direct B. Coli Aerogenes Count Obtained with Cyanide Citrate Agar to the Scoring of Shell Fish. FRED O. TONNEY, M.D., City Hall, and RALPH E. NOBLE, Chicago, Ill.

HEALTH OFFICERS

First Session—Tuesday Afternoon (*Closed Session*)

Health Department Administrative Problems, such as Salaries, Hours of Work, Vacations, Sickness Leave, Pensions, and Other Rules and Regulations. GEORGE C. RUHLAND, M.D., Health Commissioner, Syracuse, N. Y.

Discussion

National Health Contest of the U. S. Chamber of Commerce. JOHN L. RICE, M.D., Health Officer, New Haven, Conn.

Discussion. Representative of the U. S. Chamber of Commerce.

The Appraisal Form. W. F. WALKER, D.P.H., Field Director, Committee on Administrative Practice, American Public Health Association, New York, N. Y.

Discussion

Discussion of the Report of the Committee on Coöperation, Development and Finance. LOUIS I. HARRIS, M.D., General Director, Public

Health Service, National Dairy Products Corporation, New York, N. Y.

Dinner Session—Tuesday Evening (*Closed Session*)

The Place of the American Public Health Association in Public Health and the Part the Health Officer Can Play. GEORGE W. FULLER, Fuller & McClintock, New York, N. Y.

Second Session—Thursday Morning

PROGRESS REPORTS FROM THE COMMITTEE ON ADMINISTRATIVE PRACTICE:

a. The Care of Communicable Diseases in General Hospitals. D. L. RICHARDSON, M.D., Superintendent, Providence City Hospital, Providence, R. I.

b. Health Department Record Forms. GEORGE C. RUHLAND, M.D., Health Commissioner, Syracuse, N. Y.

c. High Points in County Health Work. C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn., and E. L. BISHOP, M.D., State Health Commissioner, Nashville, Tenn.

Reporting of County Health Work. H. S. MUSTARD, M.D., Assistant to the Commissioner, State Department of Health, Nashville, Tenn.

Discussion. DOUGLAS L. CANNON, M.D., State Health Commissioner, Montgomery, Ala.

Training of Health Officers. JOSEPH W. MOUNTIN, M.D., State Department of Health, Nashville, Tenn.

Discussion. M. E. BARNES, M.D., Commissioner of Health, Greenville, O.

VITAL STATISTICS

First Session—Tuesday Afternoon

SPECIAL SESSION ON CANCER

Announcement of the Purpose of the Session. *Chairman*, GEORGE H. VAN BUREN, Metropolitan Life Insurance Company, New York, N. Y.

The Need for Cancer Morbidity Statistics. FRANCIS C. WOOD, M.D., Professor and Director of the Institute of Cancer Research, Columbia University, New York, N. Y.

Problems of Cancer Mortality Statistics. H. E. ROBERTSON, M.D., Professor of Pathology, The Mayo Foundation, University of Minnesota, Rochester, Minn.

Economic Aspect of the Cancer Problem. RAYMOND PEARL, PH.D., Director, Institute of Biological Research, Johns Hopkins University, Baltimore, Md.

What Can Be Done to Give Cancer Statistics a Greater Popular Appeal?

Second Session—Wednesday Morning

Section Business.

Report of the Committee on Accuracy of Certified Causes of Death and Its Relation to Mortality Statistics and the International List.

Chairman, HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

Report of the Committee on Public Health Climatology. *Chairman,* E. W. KOPF, Metropolitan Life Insurance Company, New York, N. Y.

Report of the Committee to Coöperate with the National Safety Council in Preparing Forms for Additional Information Regarding Accidents. *Chairman,* W. THURBER FALES, Sc.D., State Registrar, State Board of Health, Montgomery, Ala.

Report of the Committee on Registration Affairs. *Acting Chairman,* T. F. MURPHY, M.D., U. S. Bureau of the Census, Washington, D. C.

Some Difficulties in the Collection of Records. STEWART G. THOMPSON, D.P.H., Director, Bureau of Vital Statistics, State Board of Health, Jacksonville, Fla.

Discussion. W. A. DAVIS, M.D., Registrar, Bureau of Vital Statistics, State Department of Health, Austin, Tex.

The Preparation and Publication of Basic Statistical Tables. L. W. HUTCHCROFT, Statistician, State Board of Health, Madison, Wis.

Discussion. F. M. REGISTER, M.D., Director, Bureau of Vital Statistics, State Board of Health, Raleigh, N. C.

No Title. SHIRLEY W. WYNNE, M.D., Commissioner of Health, New York, N. Y.

Third Session—Wednesday Afternoon

Report of the Committee to Aid Completion of the Registration Area. *Chairman,* LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Report of the Committee on Proper Allocation of Records. *Chairman,* J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

The Need of Better Occupation Returns on Death Certificates. T. F. MURPHY, M.D., U. S. Bureau of the Census, Washington, D. C.

Are the Indians Dying Out? FREDERICK L. HOFFMAN, LL.D., Consulting Statistician, Prudential Life Insurance Company, Newark, N. J.

The Variability Exhibited by Different States in the Seasonal Incidence of Typhoid Fever. GAIUS E. HARMON, M.D., Department of Hygiene and Bacteriology, School of Medicine, Western Reserve University, Cleveland, O.

The Rise and Fall of Measles Susceptibles with Epidemic Cycles over a Thirty-Year Period in Baltimore. A. W. HEDRICH, Sc.D., Instructor in Vital Statistics and Epidemiology, Johns Hopkins University, Baltimore, Md. (*Stereopticon Illustration.*)

Fourth Session—Thursday Afternoon

Report of Visits to Local Registrars of Vital Statistics in Maryland. JOHN COLLINSON, M.D., Chief, Bureau of Vital Statistics, State Department of Health, Baltimore, Md.

Tabulation of Causes of Stillbirths, Deaths of Very Young Infants, and Maternal Deaths. HENRY B. HEMENWAY, M.D., State Department of Health, Springfield, Ill.

A Setback in Mid-Life Mortality. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

The Occurrence of Influenza in a Group of Cities since 1918. SELWYN D. COLLINS, Associate Statistician, U. S. Public Health Service, Washington, D. C.

The Organization of Local Health Area Statistics in Two Hundred and Seventy Districts throughout New York City. GODIAS J. DROLET, Statistician, New York Tuberculosis and Health Association, and WILLIAM H. GUILFOY, M.D., Registrar of Records, Department of Health, New York, N. Y.

PUBLIC HEALTH ENGINEERING

First Session—Tuesday Morning

Sanitary Aspects of Collection and Disposal of Refuse (Report of the Committee on Refuse Collection and Disposal). *Chairman,* KENNETH ALLEN, City Sanitary Engineer, New York, N. Y.

The Disposal of Sewage Sludge (Report of the Committee on Sewage Disposal). *Chairman,* C. K. CALVERT, Sanitary Engineer, Indianapolis, Ind.

Sewage Disposal in Minneapolis and St. Paul. J. A. CHILDS, Chief Engineer, Metropolitan Drainage Commission, St. Paul, Minn.

Discussion. C. F. KEYES, Chairman, Metropolitan Drainage Commission, Minneapolis, Minn.

A Model Plumbing Ordinance vs. a Statewide Code. H. F. FERGUSON, Chief Sanitary Engineer, State Department of Health, Springfield, Ill.

Essential Features in the Design of Sanitary Drinking Fountains (Report of the Committee on Plumbing). *Chairman,* C. A. HOLMQUIST, Director, Division of Sanitation, State Department of Health, Albany, N. Y.

Second Session—Wednesday Morning

Bacterial Aftergrowths in Water Distribution Systems (Report of the Committee on Water Supply). *Chairman,* JOHN R. BAYLIS, Chemist, Experimental Filtration Plant, Chicago, Ill.

Water Treatment with Chlorinated Copperas. A. CLINTON DECKER, Sanitary Engineer, Tennessee Coal, Iron and Railroad Company, Birmingham, Ala., and H. G. MENKE, Assistant Sanitary Engineer, State Board of Health, Montgomery, Ala.

New Standards for Public Bathing Beaches and Wading Pools (Report of the Committee on Bathing Places). *Chairman,* STEPHEN DEM. GAGE, Sanitary Engineer, State Board of Health, Providence, R. I.

New Aspects of Shellfish Sanitation (Report of the Committee on Shellfish Supply). *Chairman,* H. D. PEASE, M.D., New York, N. Y.

Section Business and Election of Officers.

Third Session—Wednesday Afternoon

Preparedness for Disasters (Report of the Committee on Disaster Relief). *Chairman,* E. L. FILBY, Chief Engineer, State Board of Health, Jacksonville, Fla.

Lost Ultra-Violet Light Value in Urban Sunshine Due to Air Pollution. FRED O. TONNEY, M.D., and PAUL F. SOMERS, Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

Some Special Problems in Atmospheric Pollution. ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md.

Appraisal of Public Health Engineering Activities in City Health Work (Report of the Committee on Record Forms). *Chairman,* A. F. ALLEN, Health Officer, Coral Gables, Fla.

Essential Public Health and Economic Values of Mosquito Control (Report of the Committee on Mosquito Control). *Chairman,* LEWIS E. JACKSON, Hudson County Mosquito Extermination Commission, Jersey City, N. J.

INDUSTRIAL HYGIENE

First Session—Thursday Morning

What O'clock Is It in Industrial Hygiene? *Chairman's Address.* FRANK L. RECTOR, M.D., Executive Director, Chicago Medical Association, Chicago, Ill.

Section Business.

The Present Status of the Benzol Hazard in Industry. P. W. GUMAER, PH.D., The Barrett Company, New York, N. Y.

Discussion

Report of the Committee on Volatile Solvents. *Chairman,* ALICE HAMILTON, M.D., Harvard School of Public Health, Boston, Mass.

Discussion

Medical Services on an Ocean Liner. L. J. MILLAN, M.D., Medical Examiner, Bureau of Operations, U. S. Shipping Board, Baltimore, Md.

Discussion

Physical Impairment among Office Workers (A Report on One Thousand Physical Examinations of Sedentary Workers). WILLIAM A. MUHLBERG, M.D., Medical Director, The Union Central Life Insurance Company, and CAREY P. MCCORD, M.D., Medical Director, The Industrial Health Conservancy Laboratories, Cincinnati, O.

No Title. FLOYD P. ALLEN, M.D., Public Health Federation, Cincinnati, O.

Discussion. CHARLES A. NEAL, M.D., State Health Commissioner, Columbus, O., and I. C. RIGGIN, M.D., Director, American Heart Association, New York, N. Y.

Compensation for Occupational Diseases (Report of the Committee on Standard Practices in the Problem of Compensation of Occupational Diseases). *Chairman,* A. J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

Discussion

Luncheon Session—Thursday

The Worker and His Health. L. J. ZOELLER, Director of Personnel, Manufacturing Division, The Procter and Gamble Company, Cincinnati, O.

ROUND TABLE DISCUSSION OF THE OBJECTIVES OF INDUSTRIAL HYGIENE, TO INCLUDE:

Report of the Committee on Tuberculosis in Industry. *Chairman,* T. LYLE HAZLETT, M.D., Western Electric and Manufacturing Company, East Pittsburgh, Pa.

and

Report of the Committee on Industrial Morbidity Statistics. *Chairman,* WADE WRIGHT, M.D., Metropolitan Life Insurance Company, New York, N. Y.

Second Session—Friday Morning

Medical Services in Department Stores. W. JACOBSOHN, M.D., Department of Health, New York, N. Y.

Discussion. A. J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

Dusty Lung Diseases (Report of the Committee on Silicosis). *Chairman,* R. R. SAYERS, M.D., Chief of Health and Safety Section, U. S. Bureau of Mines, Washington, D. C.

Discussion

Toxicity of High Temperature Coal Tar Distillates (Report of the Committee on High Temperature Coal Tar Distillates). *Chairman,* G. H. GEHRMANN, E. I. DuPont de Nemours Company, Wilmington, Del.

Discussion

The Promotion of Health in the Manufacture of Wheat Products. No Author.

Discussion

New Skin Irritants (Report of the Committee on Skin Irritants). *Chairman,* HENRY F. SMYTH, M.D., Laboratory of Hygiene, University of Pennsylvania, Philadelphia, Pa.

Third Session—Friday Afternoon

Section Business and Election of Officers.

Occurrence, Effect and Treatment of Hydrogen Sulphide Poisoning in Industry. W. P. YANT, Supervising Chemist, Health and Laboratory Section, Bureau of Mines, Pittsburgh, Pa.

Discussion

Report of the Committee on Industrial Fatigue. *Chairman,* EUGENE L. FISK, M.D., Medical Director, Life Extension Institute, New York, N. Y.

Discussion

Lead Poisoning in the Brass and Bronze Industries. FRANK D. PEDLEY, M.D., and R. V. WARD, M.D., The Industrial Clinic of Montreal General Hospital, Montreal, Que.

Standard Procedures in Lead Poisoning (Report of the Committee on Lead Poisoning). *Chairman,* EMERY R. HAYHURST, M.D., College of Medicine, Ohio State University, Columbus, O.

Discussion

Anthrax as an Occupational Disease (Report of the Committee on Industrial Anthrax). *Chairman,* HENRY F. SMYTH, M.D., Laboratory of Hygiene, University of Pennsylvania, Philadelphia, Pa.

Discussion

Industrial Hygiene in Soviet Russia. PROFESSOR E. KAGAN, Institute for Pathology and Hygiene of Labor, Charkow, Russia.

Meeting of Section Council.

FOOD, DRUGS AND NUTRITION

First Session—Friday Morning

Report of the Committee on Dairy Products and Eggs. *Chairman,* J. H. SHRADER, PH.D., National Dairy Products Corporation, Baltimore, Md.

The Health of Anabolic Nutrition. FRANCIS L. BURNETT, M.D., Boston, Mass.

The Arsenic Content of Tobacco. E. G. LEMAY, State Department of Health, Austin, Tex.

The Vitamin Content of Ethylene-Treated and Untreated Tomatoes at Various Stages of Development. D. BREESE JONES, PH.D., and E. M. NELSON, PH.D., U. S. Department of Agriculture, Washington, D. C.

The Problem of Sweets for Children (Report of the Committee on Nutritional Problems). *Chairman,* HENRY C. SHERMAN, PH.D., Professor of Chemistry, Columbia University, New York, N. Y.

Luncheon Session—Friday

Election of Officers.

Second Session—Friday Afternoon

Protein in the Diet (Report of the Committee on Meats, Fish and Shellfish). *Chairman,* W. H. LIPMAN, M.D., Swift and Company, Chicago, Ill.

The Vitamin Content of Food in Relation to Health. HAZEL E. MUNSELL, PH.D., Bureau of Home Economics, U. S. Department of Agriculture, Washington, D. C.

Bacteriological Control in Commercial Canning. E. J. CAMERON, PH.D., and H. M. LOOMIS, National Canners' Association, Washington, D. C.

No Title. WALTER H. EDDY, PH.D., Professor of Physiological Chemistry, Teachers' College, Columbia University, New York, N. Y.

Report of the Committee on Cereals and Their Products. *Chair-*

man, F. C. BLANCK, PH.D., Bureau of Chemistry and Soils, U. S. Department of Agriculture, Washington, D. C.

Report of the Committee on Medicinal Products. *Chairman,* A. J. CRAMP, M.D., Chicago, Ill.

CHILD HYGIENE

First Session—Wednesday Morning

Morbidity and Mortality of Mothers and Newly-Born Infants. JOHN O. POLAK, M.D., Brooklyn, N. Y.

Effect of Antepartum Care of the Mother. BLANCHE M. HAINES, M.D., Children's Bureau, U. S. Department of Labor, Washington, D. C.

Effect of Prenatal Care on the Infant. HENRY F. HELMHOLZ, M.D., Mayo Clinic, Rochester, Minn.

Effect of Intrapartum Care on the Mother. J. P. GREENHILL, M.D., Chicago, Ill.

Effect of Intranatal Care on the Infant. ISAAC A. ABT, M.D., Professor of Pediatrics, Northwestern University Medical School, Chicago, Ill.

Effect of Postnatal Care on the Infant. FREDERIC W. SCHULTZ, M.D., University of Minnesota, Minneapolis, Minn.

Effect of Postpartum Care on the Mother. J. C. LITZENBERG, M.D., Minneapolis, Minn.

The Development of Maternal and Early Infant Care in Its Relation to a Public Health Program. F. J. UNDERWOOD, M.D., State Board of Health, Jackson, Miss.

Discussion. WILLIAM F. KING, M.D., *State Health Commissioner, Indianapolis, Ind.*

Second Session—Wednesday Afternoon

Report of the Committee on the Status of Maternal and Infant Mortality. *Chairman,* JULIUS LEVY, M.D., Director of Child Hygiene, Department of Health, Newark, N. J.

Coöperation of the Rank and File of the Medical Profession in a Study of Maternal and Infant Mortality. C. F. WILINSKY, M.D., Director, Beth Israel Hospital, Boston, Mass.

The Well Baby Clinic and the Office of the Family Physician and Pediatrician. E. J. HUENKENS, M.D., Director of Infant and Preschool Work, Infant Welfare Society, Minneapolis, Minn.

Third Session—Thursday Morning

What Constitutes Mental Health in the Preschool Child? HERBERT E. CHAMBERLAIN, M.D., Director, Child Guidance Clinic, Minneapolis, Minn.

The Relation of Teeth to the Health of the Preschool Child. PERCY R. HOWE, D.D.S., Chief of Research Laboratory, Forsyth Dental Infirmary, Boston, Mass.

The Significance of Proper Posture in the Preschool Child. No Author.

or

The Extent to Which Health Departments Are Justified in Maintaining Free Mental, Dental, Postural and Nutritional Clinics for the Preschool Child. No Author.

PUBLIC HEALTH EDUCATION

First Session—Tuesday Afternoon

ESTABLISHED POINTS IN A COMMUNITY PROGRAM OF HEALTH EDUCATION:

a. The Health Department's Program. HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich.

b. The Voluntary Health Agency's Field. BLEECKER MARQUETTE, Public Health Federation, Cincinnati, O.

c. The School's Health Program. WILLIS A. SUTTON, Superintendent of Schools, Atlanta, Ga.

Dinner Session—Tuesday Evening

Section Business. Closed Session for members and Fellows of Section.

Luncheon Session—Wednesday

Chairman, RAY H. EVERETT, LL.B., American Social Hygiene Association, New York, N. Y.

Health Education Questions and Answers. A. T. MCCORMACK, M.D., State Health Officer, Louisville, Ky.

Second Session—Wednesday Afternoon

Health Education as a Community Asset (*A Summary of the First Session*). IRA V. HISCOCK, Yale University, New Haven, Conn.

Discussion. MARY S. ROUTZAHN, Russell Sage Foundation, New York, N. Y.

Luncheon Session—Thursday

Chairman, PHILIP S. PLATT, New York Tuberculosis and Health Association, New York, N. Y.

Develop Health Education in Your Clinics!

Third Session—Friday Morning

What to Tell (*A Clinic Session on the Scientific Content of Health Educational Pamphlets, Posters, Exhibits, et al.*).

Chief Clinician—IAGO GALDSTON, M.D., Bureau of Health Education, New York Tuberculosis and Health Association, New York, N. Y.

Associate Clinician—EVART G. ROUTZAHN, Russell Sage Foundation, New York, N. Y.

PUBLIC HEALTH NURSING

Luncheon Session—Thursday (*Closed Session*)

Where Should the Nursing Division Stand in State Departments of Health? A. T. McCORMACK, M.D., State Health Officer, Louisville, Ky.

Discussion

Salary Schedules and Their Effect on Quality of Service. GRACE Ross, R.N., Superintendent of Nurses, Department of Health, Detroit, Mich.

First Session—Thursday Afternoon

(Continuation of Luncheon Session)

Civil Service and the Best Possible Medium That Can Be Developed in Standardizing the Appointments of Qualified Public Health Nurses. AMELIA GRANT, R.N., Director, Bureau of Nursing, Department of Health, New York, N. Y.

Discussion

Public Health Nursing Legislation. What It Should Include. MATHILDE S. KUHLMAN, R.N., Director, Division of Public Health Nursing, State Department of Health, Albany, N. Y.

What the Duties of a Communicable Disease Nursing Staff in the Health Department Should Be. AGNES J. MARTIN, R.N., Director, Bureau of Nursing, Department of Health, Syracuse, N. Y.

Discussion

Second Session—Friday Afternoon

What Should Be Included in the First-Aid Cabinet of a School Nurse? and What Should Her Standing Orders Be for First-Aid and Her School Nursing Procedure? CHARLES C. WILSON, M.D., Director of Health, Department of Health Education, Public Schools, Evansville, Ind.

What Is an Adequate Program of Supervision in Rural Communities Where the Problem Is Complicated by the Area to Be Covered —Equipment of the Staff, Nature of the Service, etc.? PEARL McIVER, R.N., Director, Public Health Nursing, Division of Child Hygiene, State Board of Health, Jefferson City, Mo.

Discussion

What, If Any, Is the Difference in the Need for Morbidity Care by a Public Health Nursing Staff in a Rural Community as Compared with an Urban Community? Is Less Service Required? If So, Why? ELIZABETH L. SMELLIE, R.N., Chief Superintendent, Victorian Order of Nurses for Canada, Ottawa, Ont.

Discussion

How Far Can a Public Health Nurse Assume Responsibility for the Social Phase of Her Health Work without Jeopardizing Her Primary Objective? KATHERINE FAVILLE, R.N., Department of Nursing Education, Teachers College, Columbia University, New York, N. Y.

What Preparation Should the Public Health Nurse Have for Rural Work? I. MALINDE HAVEY, Assistant Director, Public Health Nursing Service, American Red Cross, Washington, D. C.

EPIDEMIOLOGY

First Session—Tuesday Afternoon

Section Business and Election of Officers.

The Influenza Epidemic of 1928–1929 in the United States. SELWYN D. COLLINS, PH.D., Statistical Office, U. S. Public Health Service, Washington, D. C.

What We Know of Influenza and How We May Add to Our Knowledge. EDWIN O. JORDAN, PH.D., University of Chicago, Chicago, Ill.

Second Session—Thursday Afternoon

Practical Points in Technic of Field Epidemiology. FRANK W. LAIDLAW, M.D., District State Health Officer, Middletown, N. Y.

Relation between Collection and Use of Epidemiological Data. V. L. ELLICOTT, Epidemiologist, Health Department, Baltimore, Md.

Seasonal and Age Studies of Poliomyelitis and What They Suggest. W. LLOYD AYCOCK, M.D., Harvard Medical School, Boston, Mass.

MEETINGS OF OTHER ORGANIZATIONS

AMERICAN CHILD HEALTH ASSOCIATION

This organization will participate in the sessions of the Child Hygiene Section of the American Public Health Association. It will also hold an all-day meeting as follows:

First Session—Friday Morning

PRINCIPLES OF SOCIAL RESEARCH

Scientific Progress in Education. By an Educator.

Biometrics Applied to Public Health. RAYMOND H. FRANZEN, PH.D., Research Director, School Health Study, American Child Health Association, New York, N. Y.

Second Session—Friday Afternoon

WEIGHT, GROWTH AND NUTRITION

Chairman, THOMAS D. WOOD, M.D., Columbia University, New York, N. Y.

Introductory Remarks by the Chairman.

Results of the School Health Study. RAYMOND H. FRANZEN, PH.D., Research Director, School Health Study, American Child Health Association, New York, N. Y.

Clinical Diagnosis of Nutrition. LOUIS C. SCHROEDER, M.D., Chief, Pediatric Clinic, New York Nursery and Child's Hospital, New York, N. Y.

Contributions of Anthropometry to an Understanding of Growth and Nutrition. By an Anthropologist.

Discussion

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

First Session—Monday Morning

Address of Welcome. A. J. CHESLEY, M.D., Secretary and Executive Officer, State Department of Health, St. Paul, Minn.

President's Address. JOHN A. CECONI, M.D., Director, Department of School Hygiene, Public Schools, Boston, Mass.

The Importance of Standardizing Light in Testing Vision of School Children. B. FRANKLIN ROYER, M.D., Medical Director, National Society for the Prevention of Blindness, New York, N. Y.

Modern Methods of Testing Hearing with Special Reference to the Audiometer. A. M. KERR, M.D., Medical Supervisor, Public Schools, Pittsburgh, Pa.

Mental Safety for School Children. HERBERT E. CHAMBERLAIN, M.D., Director, Child Guidance Clinic, Minneapolis, Minn.

Physical Safety for School Children. MARION TELFORD, National Safety Council, Chicago, Ill.

Discussion

Question Box

Second Session—Monday Evening

Association Business and Election of Officers.

When Should Tonsils Be Removed? Standard Recommendations for School Physicians. J. L. BOWMAN, M.D., Health Officer, Montgomery, Ala.

The Relation of the Nutritionist to a School Health Program. CLYDE B. SCHUMAN, Director, Nutrition Service, American Red Cross, Washington, D. C.

Discussion

Question Box

Third Session—Tuesday Morning

No Title. HARRY B. BURNS, M.D., Director, Department of Hygiene, Pittsburgh, Pa.

Health Education in the Houston Public Schools. H. K. READ, M.D., Supervisor of Hygiene, Houston, Tex.

New Jersey's Continuous Child Health Program. JULIUS LEVY, M.D., Director of Child Hygiene, Department of Health, Newark, N. J.

The Selection of School Physicians. LYMAN W. CHILDS, M.D., Supervisor of Health Service, Board of Education, Cleveland, O.

Discussion

Question Box

Dinner Session—Tuesday Evening

Presiding Officer, JOHN A. CECONI, M.D., Director, Department of School Hygiene, Public Schools, Boston, Mass.

Presentation of New Officers.

Greetings from the American Public Health Association. J. H. MASON KNOX, JR., M.D., Department of Health, Baltimore, Md.

Presentation of Ling Foundation Medal to William A. Howe, M.D. By SVEN LOKRANTZ, M.D., Medical Director, Los Angeles City Schools, Los Angeles, Calif.

Health Value in Education. JAMES M. MCCONNELL, State Commissioner of Education, St. Paul, Minn.

Health a Prerequisite for Education. MATTHIAS NICOLL, JR., M.D., State Commissioner of Health, Albany, N. Y.

Coöperation by Health Education and Health Service. HUGH S. CUMMING, M.D., Surgeon General, U. S. Public Health Service, Washington, D. C.

INTERNATIONAL SOCIETY OF MEDICAL HEALTH OFFICERS

Sunday, September 29—2:30 P.M.

Meeting of the Organization Committee.

Monday, September 30—9:00 A.M.

Meeting of the Organization Committee.

Monday, September 30—2:30 P.M.

Organization Meeting of Members.

a. Adoption of Constitution and By-laws.

b. The Purpose of Our Organization. ARNOLD H. KEGEL, M.D., Commissioner of Health, Chicago, Ill.

c. Election of Officers.

Monday, September 30—4:30 P.M.

Meeting of the Executive Committee.

AMERICAN SOCIAL HYGIENE ASSOCIATION AND MINNESOTA SOCIAL HYGIENE COMMITTEE

Dinner Session—Friday

Chairman, WILLIAM F. SNOW, M.D., General Director, American Social Hygiene Association, New York, N. Y.

Evening Session—Friday

Chairman, MRS. DAVID F. SIMPSON, Minneapolis, Minn.

Social Hygiene and Social Progress. VALERIA H. PARKER, M.D., President, National Council of Women, New York, N. Y.

Social Hygiene and Public Health. C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

CONFERENCE OF STATE LABORATORY DIRECTORS

The Conference of State Laboratory Directors will be held in Minneapolis on Monday, September 30, at 3 P.M., with dinner at 6. As in previous years, the meeting will be very informal, with particular attention paid to those problems which are peculiar to the administration of state laboratories.

NORTHWEST CONFERENCE OF CHILD HEALTH AND PARENT EDUCATION

This conference plans to hold a morning session followed by luncheons on Wednesday, and an evening session on the same day; also a morning session on Thursday.

MINNESOTA STATE SANITARY CONFERENCE

There will be no formal program.

MINNESOTA STATE PUBLIC HEALTH ASSOCIATION

MINNESOTA STATE ORGANIZATION FOR PUBLIC HEALTH NURSING

HOTELS

Make your hotel reservation well in advance. For a list of hotels see the May JOURNAL, page 543.

ASSOCIATION NEWS

SEDGWICK MEDAL AWARD

The American Public Health Association announces that the first award of the Sedgwick Memorial Medal will be considered in 1929. This award was established in honor of the late Professor William Thompson Sedgwick, a former President of the American Public Health Association. The fund which provides the medal was raised by popular subscription from Professor Sedgwick's former students and friends. It is to be awarded for distinguished service in public health.

Except for the fact that it is limited to the recognition of service in the field of public health, there is no restriction as to the special line of service that will be considered. Administration, research, education, technical service, and all other specialties in the public health field will receive consideration. No limitations as to age, sex or residence have been fixed, though only those who are nationals of the countries in the American Public Health Association—at present, United States, Canada, Cuba and Mexico—are eligible.

The committee of the Association which has this matter in charge is composed of:

Homer N. Calver
Charles V. Chapin, M.D.
Lee K. Frankel, Ph.D.
Professor E. O. Jordan
George W. McCoy, M.D.
M. P. Ravenel, M.D.
M. J. Rosenau, M.D.
Robert Spurr Weston

The committee will not consider direct applications from candidates, but asks for nominations, giving the information suggested in the accompanying form. Nominations should be addressed to the Secretary, Homer N. Calver, 370 Seventh Avenue, New York, N. Y., and should include the following:

Name of the proposed candidate
Residence address
Business address
Age
Country of which the candidate is a citizen
Degrees held, date received and institutions from which received
Principal public health positions held
A brief description of the service performed because of which the candidate is recommended for consideration. This should include information as to when and where the work was done, the name of the organization or institution, if any, under whose auspices or in whose service the candidate worked, an estimation of the direct or indirect effect of the work measured in terms of life-saving or benefit to humanity. Publications, or similar data, published or unpublished, will be helpful to the committee. To be considered, the service must have been actually performed and not be merely a plan or suggestion.

Anonymous recommendations will not be considered; and the committee reserves the right to refrain from making awards in any year.

PENNSYLVANIA PUBLIC HEALTH ASSOCIATION

At the Annual Meeting of the Pennsylvania Public Health Association, held at Altoona, Pa., the following officers were elected: *President,* J. T. Butz, M.D.; *Vice President,* C. B. Maits, M.D.; *Secretary-Treasurer,* W. C. Miller, M.D.; *Assistant Treasurer,* Edgar S. Everhart, M.D. The Executive Committee consists of T. B. Appel, M.D., T. W. Henderson, A. M. Dewels, T. M. McMillan, M.D., Mrs. Lois Owen and H. C. Froutz, M.D.

MISSOURI PUBLIC HEALTH ASSOCIATION

At the Fifth Annual Meeting of the Missouri Public Health Association, held in Jefferson City, May 22–24, 1929,

the following officers were elected for the year 1929: *President,* Dr. L. Mason Lyons; *1st Vice President,* Ora Ann Carl, R.N.; *2d Vice President,* A. J. Drake, M.D.; *Secretary,* R. L. Laybourn; *Treasurer,* J. Frank Field.

NEW MEMBERS

Florence Bahn, Brooklyn, N. Y., Supervisor of Health Education, New York City Schools

Mary B. Baird, M.D., Evanston, Ill., School Physician

Eleanor Barnes, A.B., Worcester, Mass., Financial Agent, The Central New England Sanatorium and Industrial Colony, Rutland, Mass. (Assoc.)

Charles R. Blunt, Trenton, N. J., Commissioner of Labor, Department of Labor

Ethel G. Brooks, R.N., Wheeling, W. Va., Supervisor, Red Cross Public Health Nursing Service

Edwin Cameron, M.D., C.M., Beattyville, Ky., County Health Officer

A. J. Cohen, M.D., Philadelphia, Pa., Chief, Tuberculosis Division of the Department of Health

Calvin L. Cooper, M.D., Kansas City, Mo., Director of Public Health

J. W. Costello, Los Angeles, Calif. (Assoc.)

Joseph P. Kane, M.D., C.P.H., New York, N. Y., Field Director, Chautauqua Health Program

William T. Knoop, M.D., Edgewood, R. I., School Physician, Cranston, R. I.

William B. Kohn, V.M.D., Atlantic City, N. J. (Assoc.)

Edna Lewis, R.N., Tulsa, Okla., Director, Health Education, Jackson County, Mo.

William J. Lewis, Oil City, Pa., Health Officer and Milk Inspector

L. Mason Lyons, M.D., Kansas City, Mo., City Epidemiologist

Max J. Mackler, Ph.C., Ph.D., Tampa, Fla., Assistant City Health Officer

James S. McLester, M.D., Birmingham, Ala., Medical Director in Public Schools

Percy F. Murray, Peabody, Mass., Agent of Board of Health

Lillian I. Nichols, R.N., Saginaw, Mich., in charge of tuberculosis work

Terigi R. Paganelli, M.D., New York, N. Y., Eye Surgeon, Board of Education

George F. Pardee, C.E., Saugatuck, Mich., Sanitary Engineer

Ella M. Reynolds, R.N., St. Joseph, Mo., Buchanan County Health Nurse

William H. Robin, M.D., New Orleans, La., Superintendent of Public Health

Charles M. Sprague, A.B., Stanford University, Calif. (Assoc.)

John A. Stevens, M.D., Aliquippa, Pa., Beaver County Medical Director

Olga O. Teincuff, R.N., University City, Mo., Chief Nurse, St. Louis County Health Department

Robert B. Van Horn, C.E., Seattle, Wash., Assistant Professor of Civil Engineering, University of Washington

John H. Watkins, New Haven, Conn., Assistant Health Officer

DECEASED MEMBERS

R. S. Cooley, M.D., Cleveland, O., Elected Member 1924

M. R. Donovan, M.D., Lynn, Mass., Elected Member 1919

John B. Mitchell, Chevy Chase, Md., Elected Member 1923

Samuel H. Gilliland, M.D., Marietta, Pa., Elected Member 1900, Fellow 1922

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Relationship with Private Physician—The ever present question of the need of closer coöperation between the practitioner of medicine and the organized health agency is strikingly referred to in a letter by Ernst P. Boas, M.D., recently published in the *Bulletin of the Bronx County Medical Society* and reproduced in the *Weekly Bulletin* of the New York City Health Department for April 13, 1929:

> Modern trends in medical practice will continue, for although they may work harm to the physician's pocketbook, by and large they benefit the public. The physician has no proprietary rights in his patients. In his capacity as a private practitioner he has no vested monopoly in all that pertains to the health and well-being of society. Just so long as his attitude is disinterested and guided by the needs of the many rather than of himself alone; just so long as he cultivates the acquisition, increase, and practice of medical knowledge, and regards his financial reward as a by-product rather than an end in itself; he will be honored in the community, and his counsel will be respected and followed. When he becomes primarily a tradesman, he properly loses caste and influence.
>
> It is true that the increasing socialism of medicine has led to and has perpetuated a number of injustices. The physician is still expected to give a large part of his time and services to the public welfare without compensation, or with inadequate compensation. It would, to my mind, be perfectly proper for physicians to demand payment for their work in hospitals and clinics. Such work is an assumption by one class—the physicians—of obligations that properly rest upon the whole community. Propaganda and action to achieve this end may be dignified and legitimate. It will certainly be more fruitful than these blind and furious onslaughts against measures for public health or public relief that are of proven value.
>
> But in every approach to these intricate problems that involve the relationship of the physician to the community, let us remember that we are members of the profession with a noble tradition, and that in dealing with human lives there is no place for the customs and practices of unscrupulous tradesmen.
>
> And it is our county societies, the building stones of our state and national societies, pledged to an honorable code of ethics, who should primarily keep alive the idealism, integrity and selflessness of the profession of medicine.

Does Vaccination Protect Dogs against Rabies?—There has been so much controversy as to whether or not the single injection method of vaccination protects dogs against rabies that it seems wise to publish each bit of information that may help in deciding the question. Detroit has been carrying on the single injection method of vaccinating against rabies since 1924, but 1928 is the only year in which records have been sufficiently accurate to permit of a comprehensive study. The detailed results of this study have been published in the May number of *City Health* (the monthly publication of the Detroit Department of Health).

During 1928 there were 5,799 persons reported bitten by animals in the City of Detroit. It was possible to obtain accurate information by personal investigation on 2,783 dogs which had bitten people. Of this number, 581 dogs were vaccinated and 2,202 were not vaccinated. Among the 581 vaccinated dogs, there were 3 with rabies, which gives a rabies incidence of 0.52 per cent. Among the 2,202 dogs which were not vaccinated, there were 131 rabid dogs, a rabies incidence of 5.94 per cent. According to these figures, which, it must be remembered, are based on the selected

group investigated by this department, the chances of developing rabies from a dog bite are 11.4 times as great if the dog has never been vaccinated as they would be if the dog had been vaccinated.

To test the accuracy of these figures, the problem was approached from a different angle. In 1928 there were 52,263 licensed dogs. Among the dogs of which we have definite knowledge, 41.4 per cent were vaccinated. Applying this percentage to the city as a whole we find that Detroit's dog population in 1928 was 126,239. This is obviously an estimate, and too much reliance cannot be placed in it. It is believed, however, that it is a reasonable approximation. There were, in 1928, 28,000 dogs vaccinated against rabies; the remaining 98,239 were not vaccinated. Among the vaccinated dogs, there were 10 cases of rabies, an incidence of 0.36 cases per 1,000 vaccinated dogs. In the 98,239 unvaccinated dogs, there were 441 cases of rabies, an incidence of 4.49 cases per 1,000 unvaccinated dogs. From these figures, we may conclude that an unvaccinated dog is 12.5 times more likely to contract rabies than a vaccinated animal. This figure is quite comparable with that of 11.4 which prevailed among those dogs for which definite information was obtained.

While the contention that the single injection method does not protect against certain types of street virus is very likely justified, the contention that it is worthless is not true. We must admit that, as is the case with most prophylactic measures, the protection afforded is relative rather than absolute, but the fact that a vaccinated dog is approximately 12 times less likely to contract rabies than a dog which is not vaccinated seems sufficient evidence to commend its use.

If we figure the rabies death rate among dogs as if it were a human rate, we find that it is 358 per 100,000 dogs. For the unvaccinated dogs, the rate is 449, while for the vaccinated dogs it is only 35.7. It is of interest to compare these with the human death rates from certain specific causes for the same year. In 1928 the diphtheria rate per 100,000 population was 16.3; the scarlet fever rate was 4.7; the tuberculosis rate was 94.8; the typhoid fever rate was 1.0; the measles rate was 11.8 and the whooping cough rate was 6.2. The combined death rate of all these causes was 134.8.

To those interested in the conservation of dog life alone, these figures should have a dramatic appeal. The comparison with the rates for human diseases shows in a startling manner the seriousness of the situation from the canine point of view. The death rate from rabies among dogs is nearly 3 times that for all the common communicable diseases for humans put together. The lesson to be learned from a comparison of the vaccinated with the unvaccinated is obvious.—George B. Darling, Jr., Assistant Epidemiologist, Detroit Dept. of Health.

Rural Health Administration in Iowa—Word has been received from Henry Albert, M.D., State Commissioner of Health, to the effect that the Legislature has transferred the State Epidemiological Service from the University of Iowa to the State Department of Health. The tuberculosis appropriation has been transferred from the State Board of Control to the State Department of Health. The Legislature has also made provision in the State Health Department for a law enforcement division, and has added another full-time and 2 part-time engineers for special service in connection with cities, tourists' camps, highway water supplies, etc.

The most outstanding act of the Legislature, however, in the field of public health was the passage of a county health bill which permits county supervisors to organize county health units

under the direction of a board of health, to consist of not more than 11 members, 3 of whom shall be members of the local county medical society, and others, who may include representatives of local boards of health of incorporated cities or towns situated within the county, to be appointed by the county supervisors.

LABORATORY

C. C. YOUNG

SIMPLE TEST FOR DELAYED ALUM FLOC IN FILTERED WATER

FRANK E. HALE, PH. D.

Department of Water Supply, New York, N. Y.

WATERS high in color, particularly when the color lacks age, frequently show incomplete flocculation of alum previous to filtration. Aggravation of this difficulty is caused by lack of sufficiently long storage after addition of the chemicals and also by the cold temperatures of winter. This condition is sometimes indicated by alum floc gathering in the bottom of a bottle of filtered water which has been allowed to stand for 24 hours in the warm laboratory; but even when no floc appears in this case, flocculation is frequently induced by passage through the fine sand (60–120 mesh) used for concentrating a sample for microscopic examination. It then appears as amorphous matter in the Sedgwick-Rafter cell and may be so roughly estimated quantitatively. To facilitate its recognition it is best to leave a fair sized air-bubble and rotate this around the cell several times. This gathers the floc into large masses of rather characteristic appearance. To distinguish the floc further from ordinary amorphous matter just sufficient " Alizarin S " (the reagent is a 0.1 per cent filtered solution of commercial alizarin S, the sodium salt of alizarin monosulphonic acid) is added to give a slight color to the liquid. The air-bubble is then rotated when the floc will gather all the dye and leave the liquid colorless. Ordinary amorphous matter will not take up the dye in this fashion. The method also serves to distinguish delayed alum floc from aluminum in clay which is included in any chemical quantitative method. It would thus be useful in examination of distribution system samples for delayed alum floc.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Maternal Mortality—During the year 1928 there were 5,001 patients in the obstetrical service of the New York Lying-In Hospital. Of these, 3,825 were in the wards, and 1,176 were in the outdoor department. In 1927, there were 4,871 patients, 3,648 of whom were in the wards, and 1,223 in the outdoor department. During 1928 there were 25 deaths, 1 of which occurred in the outdoor service. Eighteen patients were regular applicants who had been under hospital observation, and 7 were emergency cases first seen at the time of their entrance into the hospital. Four of the fatal cases had Caesarean operations performed. There were 3 low forceps cases, all regular applicants. The causes of death among these were: pneumonia, postpartum hemorrhage and peritonitis. There were 2 emergency breech cases and 10 spontaneous deliveries. In 3 of the spontaneous deliveries the cause of death was pneumonia, in 2 peritonitis, and in 2 endocarditis.—Meyer Rosensohn. Maternal Mortality for the Year 1928 at the New York Lying-In Hospital. *M. J. & Record,* 129: 517–518 (May 1), 1929.

The Incidence of Heart Disease in School Children—A survey was made of 10,333 children in 10 public schools of Philadelphia in order to determine the incidence of organic heart disease. The average percentage of heart disease in the children of all ages was 0.91. Of 5,052 children examined in the elementary schools 0.69 per cent had heart disease, as compared with 1.11 per cent of 5,281 examined in the high schools. Of the 76 cases found in the elementary and junior high schools, 0.78 per cent were among boys, as against 1.0 per cent among girls. Thirty-nine of 94 cardiac patients had chronic valvular disease with mitral stenosis, 14 had chronic valvular disease, mitral stenosis and mitral insufficiency, and 21 had hypertrophy of the heart, chronic valvular disease and probably mitral insufficiency. The physiologic diagnosis in 85 of the cases was regular sinus rhythm. Eight cases showed mild or marked sinus arrhythmia. Thirty of the 94 cardiac cases were able to carry on ordinary physical activity without discomfort; 63 cases were unable to carry on ordinary physical activity without discomfort; and 1 case showed aggravation of symptoms even when at rest.

It is suggested that periodic school health examinations would diminish the morbidity of heart disease, by revealing cases for treatment which would otherwise be unrecognized.—Jacob M. Cahan. *J. A. M. A.,* 92: 1576–1579 (May 11), 1929.

The Poliomyelitis Outbreak in Glasgow in 1928—The first recorded outbreak of poliomyelitis in Glasgow occurred in 1928. One hundred and twelve acute cases were reported. The outbreak was confined to the 4 months from July to October, during which period 91 cases occurred. Seventy-three per cent of the 112 cases occurred among children under 5 years. The disease fell most heavily on children between the ages of 1 and 2 years, 28 of the total 112 cases having occurred in this group. Infants under 1 year and children in the age group 4 to 5 were affected to a much lesser extent. The incidence among males was 58 per cent as compared with 42 per cent among females. The dis-

ease apparently showed no predilection for any social class. Fifty-six per cent of the cases showed symptoms of feverishness and malaise. In 6 per cent paralysis was apparently the first indication of illness. In 79 per cent of the cases paralysis appeared within 7 days of onset.

Paralysis was of the spinal type in 86 of the cases, and the lower limbs were principally affected. There were 8 deaths which occurred during the peak of the outbreak. In 4 cases death occurred on the third day from the onset of illness; in 3 cases on the fourth day; and in 1 case on the fifth day. At the end of January, 1929, an inquiry was made into the 86 cases of the spinal type. Four of these cases had moved from the city and 2 had died of intercurrent affections. Of the remaining 80 cases, 10 were still in the hospital, 41 were attending as out-patients, and 29 were home under medical supervision. Thirty of the 80 cases were still wearing splints or plaster, and the remaining were receiving massage, ultra-violet ray treatment, or no treatment. Forty-three per cent of the 80 cases were considered more or less completely recovered.—*Med. Off.*, 41: 155–160 (April 13), 1929.

Capetown Health Report, 1927—There is a population of over 200,000 inhabitants in Capetown, nearly half of whom are non-Europeans. The birth rate for Europeans has declined steadily, and in 1927 it was 21.4 per 1,000 population, the lowest yet recorded. The non-European birth rate was 50.3 per 1,000 population. The European death rate from all causes was 10.7 per 1,000 population, as compared with a rate of 28.0 for non-Europeans. The death rate for 1927 was somewhat higher than for the previous year on account of an increased mortality from respiratory diseases associated with an unusually cold winter.

The death rate from tuberculosis has shown no decrease during the past 10 years, and accounts for approximately 1 death in 7. Poverty and overcrowding are the principal causes contributing to this condition.—*Med. Off.*, 41: 165 (Apr. 20), 1929.

Tuberculosis in School Children—A study of tuberculosis among 25,048 school children was made during the 1926–1927 and 1927–1928 school sessions by the Extension Department of the North Carolina Sanatorium. The children were 15 years of age and under. Of the 25,048 children tested, 22.59 per cent showed a positive tuberculin reaction. There were 22,550 white children in the group, 22.07 per cent of whom gave positive reactions, as against 27.34 per cent of 2,498 colored children. Demonstrable tuberculosis was shown in 1.72 per cent of the total number tested, or 7.62 per cent of the positive reactors.

Among the white children 1.53 per cent of those tested had demonstrable tuberculosis, as against 3.21 per cent among the colored. Of the 431 children showing demonstrable tuberculosis, 388 were classified as tracheobronchial, 23 as pulmonary (parenchymal), 4 as tracheobronchial and parenchymal, 14 as extrapulmonary, and 2 as tracheobronchial and extrapulmonary. Six hundred and seventy-four or 2.69 per cent of the total number tested were classified as suspicious. This group included those who had either strongly suspicious symptoms without discoverable cause, or x-ray findings or both.

Suspicious symptoms with no other discoverable cause, and a positive tuberculin test, especially if it is a well marked reaction, justify a tentative or strongly probable diagnosis of juvenile tuberculosis, even though the x-ray is negative—P. P. McCain. A Report of the Study of 25,048 School Children for Tuberculosis. *South. M. J.*, 22: 310–319 (Apr.), 1929.

Japanese Birth Rate in California Declining—The number of Japanese births in California has declined gradually since 1921. In that year 5,275 Japanese births were recorded in the state, as compared with 2,833 in 1928. In 1919 Japanese births constituted 8.0 per cent of all births that occurred within the state, as compared with 3.4 per cent in 1928. In so far as the actual number of Japanese births is concerned, the total number for 1928 is about the same as it was for 1912. The checking of Japanese migration to this country is undoubtedly a factor in the production of the lower birth rate, and the aging of Japanese women who were of child-bearing ages 10 years ago may constitute another factor in the changed conditions.—*Calif. Dept. of Health. Weekly Bull.*, 8: 51 (May 4), 1929.

Health Conditions in Prussia—The decline in the birth rate has continued in Prussia. In 1927 the birth rate was 19.0 per 1,000 population, as compared with 20.3 in 1926. The birth rates for the first two quarters of 1928 were 19.1 and 18.1. There were 10 infant deaths per 100 living births in 1927. For the first quarter of 1928 the infant mortality rate was 10, and for the second quarter it was 9 per 100 live births. The mortality rate from all causes was 12.6 per 1,000 population in 1927, as compared with 12.3 in 1926. For the first quarter of 1928 the mortality rate was 13.4, and for the second quarter it was 12.0 per 1,000.

There were 2 cases of smallpox with no deaths in 1928, and 3 cases with 2 deaths in 1927. Typhoid fever showed a continued tendency to recede. There were 5,326 cases in 1928, as compared with 5,919 in 1927. Diphtheria caused 30,061 cases and 1,911 deaths in 1928, as compared with 24,384 cases and 1,974 deaths in 1927, and 20,336 cases and 1,543 deaths in 1926. Scarlet fever increased from 37,864 cases and 714 deaths in 1926 to 65,497 cases and 1,030 deaths in 1927, and 85,393 cases and 874 deaths in 1928. There was a tuberculosis death rate of 9.6 per 10,000 population in 1927, as compared with a rate of 10.0 in 1926.—*J. A. M. A.*, 92: 1616–1617 (May 11), 1929.

Malaria in the Panama Canal Zone—The Health Officer of the Panama Canal announces that the malaria admission rate among the force employed there was 14.2 per 1,000 for 1928, as compared with 10.7 in 1927 and 14.1 in 1926. The average rate for the last 3 years was 13 in a force having a mean strength of 13,517. The average admission rate for 1916–1925 inclusive was 19 per 1,000. No deaths from malaria have occurred in the Panama Canal force since 1920, except for 2 in 1924.—Four Years without a Malaria Death. *J. A. M. A.*, 92: 1610 (May 11), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

RESULTS OBTAINED IN PHENOLIC WASTE DISPOSAL UNDER THE OHIO RIVER BASIN INTERSTATE STREAM CONSERVATION AGREEMENT *

WILLIAM L. STEVENSON, FELLOW A. P. H. A.

Chief Engineer, Pennsylvania Department of Health, Harrisburg, Pa.

MR. Waring's paper ably sets forth the problem of phenolic waste water disposal from by-product coke ovens; and the splendid spirit of coöperation between that industry and state health departments, and between the health departments which are parties to the Ohio River Interstate Stream Conservation Agreement.

It is gratifying to the Pennsylvania Department of Health to note that the by-product coke oven installations of Pennsylvania on the Ohio River drainage basin have coöperated 100 per cent.

Mr. Waring, probably through modesty, has not told in detail what the companies operating coke ovens along the Mahoning River in Ohio have done for Pennsylvania at the instance of the Ohio Department of Health.

A few years ago Pennsylvania water works using the Beaver River as a source of supply were grievously afflicted with offensive tastes and odors apparently having their origin from the waters of the Mahoning River, which flows through the Youngstown district in Ohio. Today, it is only occasionally that these water works have any trouble, and credit is due to the Ohio companies and the Ohio Department of Health.

Exactly the same thing is true on the Monongahela River, which is used as a source of public water supply at many points in Pennsylvania. Here the abatement of the trouble is due to the coöperation of the company operating the by-product coke oven plant on the Monongahela drainage basin in West Virginia with the State Department of Health.

We feel in Pennsylvania that companies operating by-product coke ovens have done splendid work in expending large sums of money for construction and maintenance of works for the elimination or substantial treatment of their phenolic waste waters, and the problem, therefore, has become one of efficient operation of these works and notice of accidental spills.

Under date of July 9, 1928, all companies operating by-product coke ovens in Pennsylvania, except one, executed a formal agreement with the Sanitary Water Board for the purpose of coöperating for the protection of the public health through the safeguarding of public water supplies.

This agreement obligates the companies:

(a) To maintain, in an adequate state of efficiency, equipment and apparatus for elimination or treatment of waste water actually or potentially offensive in so far as any public water supply affected thereby is concerned.

(b) To sample and test the effluents from the various plant equipment and apparatus at sufficiently frequent intervals to detect the

* Discussion of paper by F. Holman Waring. See page 758 of this issue.

presence of such offensive materials that may occur through accident, corrosion of apparatus or other causes.

(c) To notify the Sanitary Water Board promptly of any accident to the plant equipment and apparatus which might impair the efficient elimination or treatment of the said waste waters.

(d) When accidents occur, to make expeditious repair of such plant equipment and apparatus, and, meanwhile, promptly adopt emergency remedial measures.

(e) To keep the Sanitary Water Board informed of new or improved methods that may be developed for the elimination or treatment of the said waste waters and to give the Sanitary Water Board. full opportunity for determining to its satisfaction the efficacy of such methods.

The agreement obligates the Sanitary Water Board:

(a) Not to make public (excepting as provided in section (b) of this article) information received from the companies parties hereto, pursuant to Section 2(c) hereof, or to use or voluntarily furnish the same for purpose of prosecution, provided that immediate action be taken to make necessary repairs and the other provisions of this agreement be fulfilled.

(b) To give notice to water works in Pennsylvania likely to be affected by effluent from the plant where the said accident occurred in order that the operation of such water works may be modified, if practicable, in order to prevent or minimize offensive tastes or odors in the water supply as delivered to the consumers; and also to give notice to the health departments of down stream states in order that they may likewise give notice to their water works, provided, however, that in any notice given under this sub-section the name of the company at whose plant the accident occurred shall not be made public.

The agreement also provides that:

The bona fide installation and the efficient operation of means for the elimination or treatment of the said waste waters by parties of the second part in accordance with plans submitted to and approved by the Sanitary Water Board shall be deemed as compliance with the requirements of the law.

The Health Departments of Ohio, West Virginia, and Kentucky have formally agreed not to make public the name of the company in Pennsylvania where the accidental spill occurs when notice thereof is received from the Pennsylvania Department of Health, but to notify the water works which might be affected thereby of the possibility that their raw water may have offensive tastes and odors beginning on or about a certain date.

Under this Pennsylvania agreement, arrangements have been consummated with each company in Pennsylvania that it will immediately notify the appropriate district engineer of any accidental spills with necessary data concerning corrective measures taken; and a technic has been erected whereby, upon receipt of such notice, the district engineer will immediately notify all water works in Pennsylvania which might be affected thereby, and also, if it be on the Ohio River Basin, the chief engineers of the Health Departments of Ohio, West Virginia and Kentucky.

Pennsylvania was entirely satisfied with conditions in Pennsylvania on the Ohio River Basin at the important conference held in Pittsburgh in 1924, referred to in Mr. Waring's paper, but now that the Pennsylvania Companies have executed this agreement and set up the arrangement whereby water works may be warned in case of accidents, which obviously cannot be entirely prevented, we feel that the problem of protecting water supplies from wastes from by-product coke ovens in Pennsylvania is completely solved through the splendid spirit of coöperation of these companies.

Echoing Mr. Waring's closing remarks, we feel in Pennsylvania that this demonstrates the entire lack of need of federal legislation bearing upon wastes from by-product coke ovens, because of the interstate nature of the streams involved, and further that the solving of problems of this nature over the conference table rather than in the legislative halls and courts is the practical and successful method.

C. A. HOLMQUIST, FELLOW A. P. H. A.
Director, Division of Sanitation, New York State Department of Health, Albany, N. Y.

THIS very complete paper by Mr. Waring summarizes in an admirable manner the complex problems which have arisen in recent years, due to the growth of the by-product coke oven industry and the universal chlorination of public water supplies, with special reference to the conditions in the Ohio River Basin. The results achieved through conferences between state and industrial authorities indicate what may be accomplished in prevention of the pollution of streams and the improvement in the quality of public water supplies through coöperation, rather than through the arbitrary enforcement of drastic legislation.

Results similar to those in the Ohio River Basin have been obtained in New York State through coöperation with industry where 5 out of 7 by-product coke plants, whose wastes have directly or indirectly affected public water supplies, have completed works for the elimination or recovery of phenol. In only one case has it been necessary to notify the coke plant to care for its wastes and this plant is now carrying on studies to determine the most economical method of treating the wastes compatible with local conditions.

The pollution of public water supplies by phenolic wastes was first brought to the attention of the State Department of Health in 1921, when a village in the central part of the state complained of very objectionable tastes and odors in its public water supply derived from a surface stream and filtered and chlorinated before being delivered to the consumers. About the same time it was learned that the entire season's pack of a pea cannery, which used this public water supply in the process of canning, had been spoiled due to objectionable tastes and odors in the peas.

Investigations of the complaint indicated that the trouble was due to the discharge of wastes from a by-product coke plant which had just been put in operation a few miles above the public water supply intake. Various methods of eliminating the wastes were tried by the coke company with indifferent success, until finally a well 297 feet deep was drilled in limestone formation, into which the ammonia still liquor, amounting to about 90,000 gallons per day, was discharged after passing it through a sedimentation tank and coke strainer to remove lime and other suspended solids in the wastes. This well has operated now for over four years without a material reduction in its capacity, and, so far as is known, this practice has not resulted in the pollution of any ground or surface water supplies, nor have any chloro-phenol tastes occurred in the public water supply below the plant.

At another by-product coke plant in New York State, the ammonia still wastes are coagulated with copperas; settled in a pressure sedimentation tank; filtered through pressure, rapid sand filters; and then discharged into two wells drilled to a depth of about 250 feet. These wells penetrate fresh water bearing stratums which were sealed off, and then penetrate a salt water bearing stratum into which the filtered wastes were discharged. The effective preliminary treatment provided was considered necessary to prevent the clogging of the water bearing stratum.

Two by-product coke plants referred to in Mr. Waring's paper, located at Buffalo and Troy, N. Y., recover phenol from ammonia liquors by means of benzol scrubbers, and discharge the effluent into surface water streams under permits issued by the State Commissioner of Health. One plant recovers from 80 to

90 per cent and the other about 95 per cent of the phenol in the ammonia liquors. In the former case the dilution available is over 200 times as great as in the latter. These plants have been effective in removing deleterious amounts of phenol in the raw water supplies, although even now in the winter months chloro-phenol tastes are occasionally produced in one of the water supplies below the plant. This is due presumably to the fact that the body of water receiving the residual phenolic wastes is cold during the winter so that the biochemical action which leads to modification of the phenols is greatly retarded.

One by-product coke plant in this state discharges the ammonia still liquors into a municipal sewer system and sewage disposal plant consisting of Imhoff tanks. This method of disposal, which, of course, is a very economical one for the gas works, was permitted by the city only after extensive studies and experiments had shown that the discharge of ammonia still liquor into the Imhoff tanks in the proportion of 20,000 gallons of wastes to 20,000,000 gallons of sewage had no deleterious effect on the sludge or on the operation of the Imhoff tanks.

Although these tests and experiments failed to indicate that the contact of the wastes with the sewage produced any appreciable reduction in the phenol content of the wastes, the outlet of the disposal works is more distant from the water supply intake and the dilution greater than the original point of discharge of the wastes, so that the local water supply problem has been solved. While these studies were being made, the water company whose filtered and chlorinated water supply was affected instituted the permanganate treatment of the water, similar to that originated by Sir Alexander Houston of London, England. This treatment proved to be very successful in eliminating chlorophenol tastes in the water. Similar treatment has been inaugurated at another water supply derived from waters occasionally affected by by-product coke wastes.

We have received splendid coöperation from the coke plants in this state and it is hoped that this spirit of cooperation now prevailing throughout the country will be continued in the study of this complex problem, in order that more may be learned as to the best method of disposing of phenolic wastes, and eliminating this serious source of pollution to our public water supplies.

ELLIS S. TISDALE

Chief Engineer, West Virginia State Department of Health, Charleston, W. Va.

MR. Waring has made a clear, concise and complete statement which sets forth the origin of the phenol wastes and chloro-phenol taste menace to public water supplies in the Ohio River Basin, its intensification with the growth and development of the by-product coke industry, and its successful checking by the application of a new and unique principle—the working together of states carrying out a joint policy in cooperation with industry.

One of the clearest pictures of the way in which this movement has grown can be obtained by a brief consideration of the events happening at the by-product coke plant of the Domestic Coke Corporation at Fairmont, W. Va. Here in 1925, after the Interstate Stream Conservation Agreement had been entered into between the states of Ohio, Pennsylvania, and Vest Virginia and joint similar policies set up in each state, this company made an attempt to quench,

but owing to the fact that all the coke went into the domestic market the quench method had to be abandoned due to staining and odor bearing qualities of coke so treated.

Research was immediately stimulated, for the phenol had to be removed if the company was to comply with the joint state policy. Mr. Gericke had his assistant chemists, Sweeney and Jones, make careful studies of the plants at Troy, N. Y., and Lorain, O., and set about building a similar plant, operating on the benzol absorption principle; but with refinements which would raise the plant efficiency on phenol recovery. This they were successful in doing by providing for greatly increased contact by means of beds of coke between the carrier—benzol—and the counterflowing NH_3 liquor which contained the phenol.

The phenol recovery plant at Fairmont which started operation January 1, 1928, built at a cost of $25,000 per 1,000 tons of coke, the daily plant capacity, has been operating throughout these ten months at 96–98 per cent efficiency of phenol recovery and is highly satisfactory to the company in its performance.

When Sanitary Engineers Gorman, of Chicago, and Waring and Hatch, of Ohio, visited this plant in January, 1928, following the bad taste epidemic in the Chicago water supply, it was the most complete and successful phenol treatment recovery plant in operation, and it established a principle, profitable recovery, which has led to rapid changes in existing by-product plants and bids fair to revolutionize the old wasteful quench method of phenol wastes disposal.

The fact that three states in 1924 set up and agreed to a fundamental policy for phenol wastes disposal, which they proposed to carry out by coöperation with industry, stimulated research to a remarkable degree. Not only did the Fairmont plant build a successful phenol recovery plant, but the recovery promised to meet operating charges and possibly fixed charges with a possibility of profit, when refinements were made. Also, the Koppers Company speeded up its experimental work along another line which has resulted in the new and successfully operating recovery plant at Hamilton, O., spoken of by Mr. Waring. This plant recovers more than 98 per cent of the phenol, according to the latest advices, and is simple, positive, and easy of operation. The two new phenol recovery plants at Ironton, O., and Ashland, Ky., which are to be operated on the "light-oil" absorption process, indicate the rapidity with which the program of phenol recovery has gone forward. The Ironton plant was started June 1, 1928.

West Virginia has recently, through joint conferences with the Ohio State Health Department and representatives of industry, provided for the completion of the program of phenol removal from the Ohio River from West Virginia coke plants where final action had not been taken, so that the summer of 1929 should see all phenol wastes out of the Ohio.

In connection with the question of tastes, it is of considerable interest to note that the 98 per cent of removal at Fairmont has eliminated tastes from the Morgantown water supply, and the public water supplies in Pennsylvania on this stream are no longer detrimentally affected by wastes from the Fairmont plant in West Virginia. Likewise the improvement in phenol wastes treatment at Midland, Pa., on the Ohio River above the West Virginia line, has markedly reduced the tastes in the Wheeling water supply. In 1927 bad tastes were recorded on 8 days by G. E. Richard, superintendent of this new filtration plant, and in 1928 only once were phenol tastes recorded. The 100 per cent success already achieved in Ohio in removing phenol wastes has likewise

been a big factor in the decrease in tastes at Wheeling and in other West Virginia Ohio River supplies this year. With the completion of two new phenol recovery plants on the watershed in West Virginia above Wheeling, chlorophenol tastes should become a matter of history.

Certain very definite advances in the public water supply field have been made since the Interstate Stream Conservation Agreement was adopted by Ohio, Pennsylvania and West Virginia in 1924:

1. By its complete success it has been demonstrated that a coöperative policy between states and with industry will work.

2. Carrying this program on the Ohio River Basin to a successful conclusion has been hastened greatly by the recent invention and improvements in phenol recovery processes, which work was stimulated by the coöperative state program.

3. It appears likely that practically all new by-product plants will install phenol recovery processes when the by-product plant is built, since at the present stage of development phenol recovery is on almost a self supporting basis and by-product plants now using the quench method will gradually revamp their works to recover phenol and save the very high depreciation losses involved in the quench method.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Heart Disease and Industry—Heart disease more than any other malady seriously affects the life of the industrial worker. Symptoms of organic heart disease are first complained of after exercise—breathlessness, particularly in the region of the heart, giddiness, fainting, exhaustion and palpitation. Those in heavy work complain first. Not more than half of the workers who break down before the age of 40 with heart symptoms, however, have organic heart disease.

Rheumatic infection is the chief cause of organic trouble, but general ill health likewise accounts for many cases of heart symptoms. Only a small portion with rheumatic heart disease live past the age of 40. After 40, syphilis leads to premature death from heart disease in a small number. Five-sixths of the total number of deaths from heart disease occur after age 40, and the principal cause is a degenerative process of senescent type. Hence, the importance of recognizing this condition early. A suitable occupation, healthy home conditions, and proper medical supervision can prolong the working life of these individuals.

A sanatorium form of treatment should lead to a considerable lowering of heart disease deaths, particularly those of the rheumatic type. Two special convalescent homes for boys and girls with heart disease have been established in London. The economic waste and financial strain on the insurance funds for this disease should cause the public to realize the benefits of convalescent homes, whose cost is comparatively infinitesimal.—Thomas J. Cotton, *J. State Med.*, 37, 2: 100–106 (Feb.), 1929.

The Effects of Labor Legislation on the Employment Opportunities of Women—(Abstract of Summary). With each decade women employees have increased among the gainfully employed. More significant is the great development in the kinds of work open

to them. They have likewise assumed a steadily increasing importance of positions. At the same time, labor legislation applying to women has shown extensive increases, although this is very uneven in the various states, so that not over one-third enjoy legislation limiting hours of work. Massachusetts and California in particular have set up laws governing minimum standards for women's employment. These laws are of two types—those that regulate, and those that prohibit. In the matter of regulations, many qualifications and exemptions are permitted; likewise, legislation is only effective where it is enforced. Hence, conclusions as to the effects of legislation must be drawn with great caution.—Women's Bureau, U. S. Dept. Labor, *Bull. No. 68*, 1928, 22 pp.

The Health of Women and Girls in Relation to Industry—Our intelligent girls from the industrial classes when they leave school usually become highly skilled workers, and when they marry they are far better off because they may continue at such work when, owing to industrial depressions, the husband is out of work. True, there is very little leisure in their lives. Their physical fitness should be vouched for after medical examination. Among practical tests, acuity of vision is specially important, since one encounters women who have passed through all of the standards of the elementary school, but who from disuse have lost the power to read.

Likewise, mental defects, middle ear disease, dysmenorrhea, and defects following childbirth are prominent and lamentable, the more so because so many may be corrected. The mother of a family who has not been damaged in childbirth is perfectly fit for hard physical work. During the War, the author recalls three cases of direct inguinal hernia, as the result of work on lathes; no woman developed an indirect inguinal or femoral hernia; no woman with an intact pelvic floor developed any uterine displacement; and no woman developed cardiac incompetency where the heart was sound on engagement. Work in no way conduced to sterility, but even appeared to render some more fertile. The rate of purposeful abortions was proportional to the rate pregnant women were discharged. When the women were permitted to continue work which was suitable to them, no abortions followed, and they came to term with excellent results, both to themselves and to their children.

The author's practice has failed to find defects in women attributable to hard work, during the war or afterward. The principal point is, physical fitness of women for work, and not that women should not work. "There is no inherent incapacity for hard work in women as a sex, and public opinion and legislation" should be changed in this respect.—Mrs. R. H. B. Adamson, *J. State Med.*, 37, 2: 107–113 (Feb.), 1929.

Women Workers in Flint, Mich.—This bulletin summarizes various conditions of the employment of women, including hours, earnings, working conditions and personal history. The median of the week's earnings was $16.50, and of the year (for 132 women) $775. The usual work day was 8½ to 9 hours, with a short day on Saturday, except in stores. More attention was given to lighting than to ventilation; and particularly, the effect of too much heat and steam did not receive sufficient attention. Inadequate seating was often present. It was found that 31 of the 34 establishments had insanitary drinking "bubblers," and 21 plants were using the common drinking cup. The common towel was found in 56 establishments, and no towels in 24. Toilet facilities were sometimes inadequate. (The bulletin should be consulted by

those interested further.)—Women's Bureau, U. S. Dept. Labor, *Bull. No. 67*, 1929, 79 pp.

Child Labor—This bulletin contains a series of six articles prepared respectively by William John Cooper, U. S. Commissioner of Education; Hugh Grant Rowell, M.D., Teachers College, Columbia University; Olive A. Cooper, M.D., Massachusetts State Department of Mental Hygiene; Weaver Pangburn, Playground and Recreation Association of America; Sidonie M. Gruenberg, Director of the Child Study Association of America; and William Green, President, American Federation of Labor. (Space does not permit more than this mention.)—National Child Labor Committee, 215 Fourth Avenue, New York, N. Y., *Pub. No. 352*, May, 1929, 39 pp.

Trends in Personnel Health Service—This bulletin discusses in Part I the agencies interested in the promotion of organized health and sanitation activities, both prior to and since 1910. Part II takes up industrial groups, including the activities of various industrial associations, many leading companies and corporations of the United States, as well as the efforts of organized labor and joint boards of sanitary control. Among associations, societies and institutions, the names and dates of organization are given for 24. Under "public agencies" are listed the principal medical schools, federal and state departments, bureaus and agencies. Legislation has been concerned principally with reporting, prohibition, regulation and compensation or insurance.

The article ends with a brief summary of the principal literature, and the statement that prior to 1880 the *Index Catalogue* of the Surgeon General's Library shows there were but 5 books, and 75 articles relating to industrial hygiene or occupational diseases by American authors. During the period 1880–1900, American authors made but 22 contributions. From 1900, and more especially from 1908, such contributions increased to the extent that by June 30, 1921, 702 subjects had been indexed in the Library of the Surgeon General's Office.—W. H. Lange, American Management Association, 20 Vesey Street, New York, N. Y., *General Management Series: No. 85*, 1929, 48 pp.

Reporting of Occupational and Industrial Diseases—The first essential in preventive medicine is to know where, and in what numbers, diseases occur; hence, an active law requiring that all physicians report certain well-known and definite diseases to one central department of government having jurisdiction in matters of public health. The next feature is the matter of what to do about such afflictions as occupational diseases and accidents. The problem is how to apply preventive medicine to this situation. However, the result of the lack of coöperation of the physicians has not brought about the ends desired. In the past 4 years, less than 10 physicians, and not more than 5 hospitals (in New York State) have reported occupational diseases. Industrial hygiene is one of the most important subjects of public health, as it deals with nearly one-half of the adult population.

Greatly increased coöperation on the part of the medical profession is necessary, and among the first essentials is the reporting of occupational diseases.—Robert S. McBirney, New York State Bureau of Industrial Hygiene, *Indust. Hyg. Bull.*, 5, 11: 40–44 (May), 1929.

Inadequacy of Present Provisions for Rock Dusting in Coal Mines—The U. S. Bureau of Mines reports in a recent circular (No. 6087) the results of a recent survey on rock dusting in coal mines. This survey disclosed the fact that rock dusting provisions are

woefully inadequate in the United States, and that but a small fraction of 1 per cent of coal mines is adequately protected by rock dust. During the fiscal year ending June 30, 1928, 22 explosions in bituminous mines were reported to the U. S. Bureau of Mines, with 320 fatalities. Of this number, 10 mines with 258 deaths were supposed to have been using rock dust. Investigation, however, revealed the fact that the measures were inadequately enforced because of a lack of proper comprehension of their value. The cost of rock dusting is approximately 1 cent per ton of coal so that the element of cost should not be a bar to its very widespread adoption. It is hoped that rock dusting of mines will increase rapidly in the near future.—U. S. Dept. Labor, *Month. Labor Rev.*, 28, 2: 240 (Feb.), 1929.

L. G.

Physiological Response Attending Exposure to Vapors of Methyl Bromide, Methyl Chloride, Ethyl Bromide and Ethyl Chloride—The authors discuss the apparatus and test procedures and results of investigations upon the substances named in the title, some of which are used in refrigeration. A table on page 31 summarizes the physiological response to various concentrations of some 17 common gases and vapors.—R. R. Sayers, W. P. Yant, B. G. H. Thomas and L. B. Berger, *Pub. Health Bull. 185,* 1929, 56 pp.

Quarry Accidents in the United States in 1926—According to the recently published report of the U. S. Bureau of Mines, there was an increase from 1.78 in 1925 to 1.87 in 1926 in the fatality rate per 1,000 300-day workers, and a decrease from 169.67 to 160.28 in the injury rate. Measured by the fatality rate, the accident hazard appears to be greatest in granite quarrying (3.52); next in marble quarrying (3.12). The injury rate was highest in trap rock, being 244.92; limestone being next with a rate of 207.39. The cause of fatal accidents in order of importance was as follows: falls or slides of rock or overburden, explosions, haulage, machinery, electricity, falls of persons and burns. Most of the non-fatal injuries were caused by flying objects, handling rock, machinery, haulage, falling objects, falls of persons, hand tools and falls or slides of rock or overburden.—U. S. Dept. Labor, *Month. Labor Rev.*, 28, 2: 239 (Feb.), 1929. L. G.

Occupational Dermatitis—The Bureau of Women in Industry of the New York State Department of Labor has recently completed a study of 390 cases of dermatitis of industrial origin. It was found that 24 per cent were of over 1 year's duration, 21 per cent lasted from 1 to 3 months, and 16 per cent from 4 to 6 months. Ninety-one of the cases began on the hands and spread to other portions of the body. Thirty cases were primary and in other locations, chiefly the legs. Dermatitis on the face appeared to be chiefly a result of carrying irritating substances to the face by the hands of the worker. The largest percentage of cases was caused by soap and soap cleansers. The next largest group was due to dyes and lime. Other causes were lead, ink, flour, sugar, chromic acid, methylene alcohol, etc. One hundred and eighteen cases were associated with house work; included among these were porters, janitors, restaurant workers and building cleaners. The constant handling of carbon paper was a source of dermatitis among stenographers.—U. S. Dept. Labor, *Month. Labor Rev.*, 28, 4: 782 (Apr.), 1929. L. G.

Industrial Accidents in Massachusetts, 1926–1927—The Department of Industrial Accidents of the State of Massachusetts has recently issued the report of the industrial statistics for the 15th year (ending June 30, 1927). The

report indicates a decided increase in the number of accidents over the previous year, and also an increase in the number of tabulatable injuries, the latter being increased from 36.7 to 38.3. The most frequent cause of death was associated with vehicles, the next in order being falls of persons. The most frequent cause of permanent disability was machinery, the second most important cause being handling objects. The most frequent cause of temporary disability was handling objects, falls being the second most important cause.—U. S. Dept. Labor, *Month. Labor Rev.*, 28, 2: 242 (Feb.), 1929. L. G.

Spray Painting Practices and Hazards—This is a report of an investigation of spray painting methods and hazards in 71 manufacturing and mercantile establishments and 8 government posts, to determine (1) what has been done to overcome the hazards of the process, and (2) what can be done further to protect the worker or eliminate the inherent dangers of the method.

Experience with the use of the spray apparatus in the various plants ranged from 2 months to 20 years. Investigations showed that 36 plants had 1 case each of poisoning; 6 establishments had 2 cases, 2 establishments 3 cases, 2 establishments 5 cases, and 1 plant 6 cases of illness. Twenty-four plants reported no trouble of any kind. Six of the cases resulted in death, while in the remaining a disability up to 1 year's duration was the chief outcome. Most of the cases reported were lead poisoning. There were several cases of lacquer poisoning, 2 cases of benzol poisoning, and 1 case of turpentine poisoning.

Among substitutes for toxic materials titanium oxide is especially recommended in place of lead, and iron oxide in some instances. Experiments conducted by the U. S. Navy indicate that lead can be eliminated entirely by such substitutes which are found to be equal to lead in all qualities studied. Toluol, xylol and similar materials may be substituted for benzol.

It was found that family physicians were treating these cases for ailments based on the outstanding symptoms under such diagnoses as: stomach trouble, appendicitis, etc. Small plants were, as a rule, the more dangerous places. In a few large plants employing as many as 200 to 300 spray operators there have been only one or two slight cases of disability in the course of several years' experience.

In addition to adequate ventilation provisions, additional protection, it is pointed out, may be secured by the enforcement of high standards of personal hygiene, instruction in the proper use of the spray gun, the use of wet sand papering methods in place of dry methods, the use of as low pressure spraying as is consistent with satisfactory output, and the use of non-toxic materials in so far as possible.—U. S. Dept. Labor, *Month. Labor Rev.*, 28, 5: 915 (May), 1929. L. G. & E. R. H.

Electrical Accident Prevention—This circular discusses the prevention of electrical shock, the safeguarding of machinery and apparatus, both upon the surface and underground; the prevention of gas ignition and explosions; the suggestions for improvement; and mine-fire prevention.—L. C. Ilsley, U. S. Bu. Mines, *Circular No. 6100*, Feb., 1928, 8 pp.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Experimental Hypervitaminosis—In order to determine the effects of massive doses of vitamin D, 24 white rats, 3 weeks old, weighing 50 to 60 gm., were placed in 3 different cages and kept in the dark on a rachitic diet No. 3143 of McCollum and coworkers. In the first group, 8 control rats were placed on the vitamin diet; in the second group, 8 were on the same diet with the additional dose of 5 mg. of irradiated ergosterol (Vigantol) a day in ½ c.c. of 1 per cent solution of olive oil, and in the third group, 8 animals on the same diet with the addition of a dose of 3 drops of cod liver oil per day. Between 3 and 5 weeks all of the animals receiving the excessive dose of ergosterol died, this dose being about one thousand times higher than that used by Gyorgi and other investigators. Those in groups 1 and 3 at the end of the 5th week showed no deleterious effects. They kept their appetite and developed well.

A second experiment of overdosage gave the same results. Four rats receiving the excessive doses were taken from the cages and the dosage stopped. After that the result on health, appetite, development, and increase in weight was favorable, similar to the control rats. The remainder of the rats receiving the excessive ergosterol gave the same severe pathological changes, and death occurred within the 4th and 5th weeks.

The authors describe the symptoms of hypervitaminosis which they term "Vitaminismus." These are chiefly: general loss of weight of 30 per cent despite a relatively good appetite, arrested development, increased temperature, rough coats, and, in some cases, paralysis of the legs. The authors discuss 3 manifestations of so-called "Vitaminopathy": (1) through deficiency or hypovitaminosis; (2) through excess or hypervitaminosis; and (3) through lack of coördination between the different vitamins or dysvitaminosis. The importance of this knowledge is stressed in the application of vitamin supplements in the treatment of children's diseases and it is concluded that the results are as remarkable as the original discovery of vitamins. The dose of vitamin D administered was 5,000 to 50,000 greater than that ordinarily employed so that the difference between the necessary and the fatal dose is great and difficult to estimate in the case of man. —J. A. Collazo, P. Rubino, and B. Varela, *Biochem. Ztschr.*, 204: 347 (Jan.), 1929.

"Hypervitaminosis" and "Vitamin Balance"—Previous investigators have reported injurious effects of excessive doses of vitamin D, most of the work published relating to cod liver oil or its concentrates as the source of this vitamin, although in some of the recent work irradiated ergosterol was used. The present work was done on growing rats and the vitamin preparations were administered with the ration instead of separately. In one experiment young rats weighing 40 to 50 gm. each were given synthetic diets containing irradiated ergosterol in the concentrations 0.00001, 0.001, and 0.1 per cent, the controls being given the same dose of non-irradiated ergosterol and heated ergosterol, and some no ergosterol. In addition, each animal received 2 drops daily of cod liver oil and an alcoholic extract of marmite. All animals re-

ceiving 0.1 per cent of irradiated ergosterol lost weight and died after 20 days; those with smaller concentrations grew normally and appeared to thrive. No ill effects were observed on the controls receiving heated or non-irradiated ergosterol. The rats on the high concentrations suffered inanition, diarrhea, and developed lesions on the hind paws, as well as greasy and rough coats. Post-mortem appearance resembled vitamin B deprivation.

An experiment was conducted to see if the deleterious effects of the ergosterol could be offset by an increase of vitamin B (Complex). The marmite dose was increased to 4 times the normal level but with negative results. Two animals given fourfold marmite with added wheat germ extract and orange juice maintained weight and apparent good health while the controls with unsupplemented diets declined. Rats refused to eat synthetic diets containing 250 mg. of irradiated ergosterol while they readily ate those of the same amount of non-irradiated ergosterol.

In another experiment rats were offered synthetic diets containing (1) non-irradiated ergosterol, (2) irradiated ergosterol, and (3) no ergosterol. Non-irradiated ergosterol was eaten in preference to the irradiated. In animals deprived of vitamin B, growth stopped and death took place at about the same rate irrespective of the amount of vitamin D in the diet. Rats receiving a thousand times the necessary vitamin D succumbed to B-avitaminosis at the same rate as those receiving no vitamin D in the diet. Similar diets were fed two sets of rats with the exception that one received 15 per cent of the fat in potent cod liver oil and the other the same fat content in peanut oil. These sets were then placed on different allowances of standard marmite to note the effect of vitamin B intake. The cod liver oil rats grew slower than the ones on peanut oil. Differences were most marked in the intermediate marmite concentrations adequate for maintenance. Only small differences were observed at the highest and lowest marmite levels. In this experiment no litters were obtained from the cod liver oil group, but on the peanut oil group 7 litters were obtained, all from the rats receiving a maximum marmite extract in the diet.

Cod liver oil concentrate (unsaponified matter of cod liver oil) was administered to one of two groups of rats on standard diet without marmite addition. Both groups showed vitamin B deprivation, but the loss in weight was more rapid in the group receiving the concentrate. The condition in this group ultimately resembled pellagra.

The authors conclude that while the results indicate toxic properties attributed to vitamin D the question is complicated by the fact that vitamin D cannot be administered at the present time free from impurities and that the toxic substance might be attributed to accompanying impurities, and the further possibility that the excess vitamin D unbalances the vitamin B allowance.

Further experiments are in progress to determine the effects of ergosterol which has lost its vitamin D through over-irradiation and the effect of vitamin D upon calcium and phosphorus metabolism.

The authors caution against alarm in the use of commercial preparations since the doses shown to produce toxic effects were greatly in excess of those which would ordinarily be employed in practice.—Leslie Julius Harris and Thomas Moore, *Biochem. J.*, 22: 1461, 1928.

The Commercial Application of Lactobacillus Acidophilus Milk—This is a brief review of the literature on the therapeutic value of *L. acidophilus* in milk culture; the report of studies on the isolation of the organism from the feces of rats on high lactose diets, the

change in the intestinal flora of rats following feeding with *L. acidophilus* cultures, and the growth and viability of the organism under varying conditions; and a description of the commercial method of manufacturing acidophilus milk with general directions for its use. An extensive list of literature references is appended.—E. L. Reichart and H. P. Davis, *Nebraska Sta. Bul. 228,* 1928, p. 19. Abstract, *Exper. Sta. Rec.,* 60: 593 (Apr.), 1929.

Antineuritic and Water-soluble B Vitamins in Beef and Pork—Pigeons were used as experimental animals and the controls were fed a basal diet practically devoid of antineuritic vitamin B. In experiment No. 1, supplements of beef and pork were used. Five per cent fresh ham protected pigeons against polyneuritis for 70 days; 10 per cent fresh ham protected pigeons at the same time; and 20 per cent dried beef failed to protect against polyneuritis and loss of weight, but 40 per cent dried beef protected the birds for 70 days.

A second experiment was performed in which the rice in the basal ration was heated 1½ hours under pressure to destroy any antineuritic vitamin present, as against unheated rice for the first experiment. Pigeons on the basal ration developed polyneuritis earlier than in experiment No. 1. Neither 5 nor 7.5 per cent of dried baker's yeast prevented polyneuritis. Five per cent of dried brewer's yeast offered protection for at least 8 weeks but one bird developed the disease on the 40th day. Dried beef in the amounts of 12.8, 21.4, and 34.2 per cent was tried but the maximum was hardly sufficient as a protective, one pigeon in this lot developing polyneuritis. Five per cent of smoked ham protected all pigeons in this experiment against polyneuritis for 8 weeks. Albino rats were used in testing water-soluble B vitamins, the controls being fed the basal ration until gain in weight stopped. Three lots of fresh and two of dried ham in amounts varying from 10 to 24 per cent were fed and no material difference noted; good growth and gain in weight resulted when the percentage of ham was 15 or more. Dried fresh beef was tested for water-soluble B vitamins in 4 lots, 40 per cent supplement being insufficient for material growth. On 70 per cent supplement the rats grew rapidly. For comparison purposes it was found that dried brewer's yeast in 5 per cent supplement and baker's yeast in 7.5 per cent furnished sufficient water-soluble B for excellent growth.—Ralph Hoagland, *J. Agri. Res.,* 38: 431 (Apr. 15), 1929.

The Effect of Heat on the Antineuritic Vitamin of Milk—This investigation covers three types of dried milk: one, made by the spray process; a second, made by superheated rollers, and a third, a desiccated albumin milk. In addition, tests were made of commercially pasteurized and home pasteurized milk, and of milk quickly boiled. Various mixtures of these preparations were given to suckling rats whose mothers were on high protein ration. Tables are given showing the various supplements to the ration and the gain and loss in weight of the animals. The results indicate destruction of the antineuritic vitamin in all of the superheated milk except that made by the roller process. Similar results are apparent in the milk pasteurized by the open method, while that pasteurized by the closed method showed no vitamin destruction. Milk heated to boiling temperature quickly and cooled slowly is severely affected, while the same milk cooled quickly shows no adverse effect. The authors conclude that temperature and aeration are important factors in the destruction of the antineuritic vitamin. —Amy L. Daniels, Mate L. Giddings, and Dorothy Jordan, *J. Nutrition,* 1: 455 (May), 1929.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

The Nursing Division of the League of Red Cross Societies—At the time of the foundation of the Red Cross Societies at Geneva, in 1864, there was recognition of the value of nursing as an indispensable part of its activities, and recommendations were made from time to time relative to the type of person best fitted for nursing service. Ever since 1907, there have been peace-time programs in the Red Cross Associations for training nurses in the care of the sick either through short special courses, or the formation of training schools attached to hospitals, with the idea of preparing them for participation in any emergency such as war, epidemics, or floods, which might arise.

Since the World War, the conception of the nurse's function has broadened to conform to our larger viewpoint in regard to health work. At the medical conference in Cannes in 1919, it was recommended that a department of nursing, under the direction of a qualified nurse, should be organized as part of the League of Red Cross Societies. The purpose of this department was to assist the Red Cross Societies in their different countries, and to establish a postgraduate training center. Certain resolutions about the needs in regard to nursing service were drawn up at that time.

Soon there followed the formation of the Nursing Advisory Board, representing various nursing organizations from different countries, and the recommendations of this board, which were accepted by the Third General Conference of the League in 1924, were in line with the resolutions introduced in the earlier conferences. They were:

1. That the development of nursing should form a vital part of the program of each national Red Cross Society.
2. That societies should endeavor to stimulate the development of schools of nursing of the highest order in their respective countries provided that institutions of this character do not exist.
3. That, in future, national Red Cross Societies should designate as Red Cross nurses only those graduated from these schools of a high order, and that the group of women trained by Red Cross Societies for emergency purposes be designated by some such title as "Voluntary Aid Detachments," or "Sanitary Aids," and should serve under enrolled Red Cross nurses.
4. That national Red Cross Societies should promote the efficient education of public health nurses, whenever the Red Cross Society is engaged in health activities where public and private organizations look to the society for assistance in health work.
5. That national Red Cross Societies should endeavor to promote in the minds of the public in their respective countries the national importance of the nurse, and to work for the advancement of nursing education and the improvement of the social and economic status of the nurse.
6. That national Red Cross Societies should enroll in a nursing reserve all the qualified nurses in their countries who would be in a position to respond in time of war, disaster, or epidemic.
7. That each national Red Cross Society should appoint an advisory nursing committee of leading nurses and representatives of the medical profession, and of the health, educational and hospital authorities, to study the needs, determine the activities, and guide the development of any activities undertaken by the Red Cross.

Since then, the Advisory Board has been altered to a small Advisory Committee representing different racial groups, with an *ex officio* representative from the International Red Cross Committee, and a representative of the country in which the meeting is being held.

The two international courses for

postgraduate instructions, organized according to the original recommendations, have up to the present time received about 141 students from different countries. The schools are centered in London at Bedford College for Women, in conjunction with the College of Nursing; one being a course in public health, and the other a course for nurse administrators and teachers in schools of nursing. A permanent residence for the international students is maintained at 15 Manchester Square.

A further activity of the League in regard to nursing has been the loaning of fully trained nurses to countries having no training schools, for the purpose of starting schools according to the methods now accepted as standard in western countries. These schools have been undertaken with the idea that they were to be transferred to native graduate nurses as soon as possible for permanent development. Sometimes, where the need of certain countries has been for money to maintain schools rather than for nurses, this has been supplied through the League. There are now about 160 schools of nursing in different parts of the world, conducted by the Red Cross Societies. Public health nursing is being incorporated in the training as much as possible, and travelling scholarships have made foreign study possible.

Public health activities in maternal and infant welfare, tuberculosis, and school nursing, have made possible advances in sections of the world formerly untouched by health work. In disaster relief, the public health nurses have given their usual prompt and efficient aid.

In assistance to Red Cross Societies in their own countries, the activities of the Nursing Division may be described as follows:

Setting up a clearing house for information on nursing subjects, and collecting, compiling and distributing information on the development of nursing in different countries for the use of Red Cross Societies

Maintaining a package library on nursing and associated subjects

Continuing an advisory relation with students who, having completed the International Course, are at work in their own countries

Providing pictures, films, exhibits, pamphlets on nursing

Preparing or securing articles for *The World's Health*

Offering advisory service to national Red Cross Societies through correspondence, visits at League headquarters and visits to the individual Society

Promoting regional Red Cross Conferences for nurses.—

Elizabeth Gordon Fox, Out of an Idea Has Grown a Great Pioneer Service, *Red Cross Courier*, VIII, 9: 25 (May 1), 1929. K. E. P.

Grant for Dental Research—Nowadays, dentists send periodic gentle reminders urging that teeth need attention, so we take our courage in hand and go, realizing that if we preach prevention it is just as well to practice it. Before long, we may know the reasons underlying the need for prophylaxis. The Yale School of Medicine has effected a plan for intensive study of the teeth in relation to the body in general, and a grant from the Rockefeller Foundation has made the project possible.

A study group composed of physicians, surgeons, radiologists, bacteriologists, dentists and pathologists has been formed, with Milton C. Winternitz, M.D., Dean of the Yale School of Medicine, as chairman. Clinical investigations of the condition of the teeth and the bacteria to be found at their roots will be carried on in coöperation with fundamental research in the structure and function of the teeth in health and disease. The germs found at the roots will be isolated and studied in relation to germs found in the mouth and in other parts of the body, and their effect upon the organism. The purpose is not to interfere with training in dental technic as now practiced in schools of dentistry, but to create a group of medical specialists in teeth. Each year from 2 to 4 graduates of dental schools will be admitted to the School of Medicine to continue their medical studies and to work with the dental pathology study group.

How Is Your Blood Pressure?—What blood pressure is:

Circulation of the blood through the arteries, capillaries and veins takes place through the exertion of constant pressure of the blood stream against the elastic walls of the arteries.

This degree of pressure varies constantly, depending upon activity. The highest point of pressure is reached during the time when the pulse "beats" and is called the systolic pressure. The lowest point, the diastolic pressure, represents the degree of pressure existing between "beats." The variation in the levels to which these two points rise and fall is not great in the normal person. But a condition in which the degree of systolic and diastolic pressure remains at too high a level is an accompaniment and perhaps a contributing cause to many serious middle-age and old-age diseases. This condition is known as hypertension and is one which develops slowly, aided markedly by wrong habits of living. It is much easier to prevent than to cure.

How to avoid hypertension:

The prevention is mainly through the avoidance of physical or emotional excesses. The way you live and think now is going to have far more to do with your blood pressure 50 years from now than any amount of medicine you can take then.

A few good suggestions are:

1. Moderation in eating, smoking, drinking, exercising, and any activity which worries you or tires you out
2. Regularity in eating, sleeping, bathing and eliminating
3. Ruling fear and anxiety, especially about yourself, out of your life

For the older person with high blood pressure, a quiet life and a contented mind will do more than all the medicine in the world to reduce it to lower levels. Periodic consultations with the doctor are necessary for the maintenance of health.—Norman B. Cole, How Is Your Blood Pressure? *Hygeia*, 7, 5: 459 (May), 1929. K. E. P.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

How to Get Exhibits Done—There are many possibilities for the resourceful and lucky person to enlist volunteers for various kinds of exhibit construction.

There are skilled and enthusiastic amateurs in all types of craftsmanship who might be enlisted if your project is appealing to the particular individual whose aid is desired—workers in metals, wood, cardboard, electricity, chemicals, photography, and so on.

Instructors in the above may sometimes be interested in doing what you need—because of interest in the craft or the appeal of your work.

There is always the possibility that the commercial specialist may become interested in your particular project, and be willing to make a contribution of service or material, although this approach must be as carefully guarded as a request for a financial contribution.

Individuals or groups of unskilled volunteers—neat, systematic and interested—may do certain types of work: cutting, pasting, and other simple operations.

The executive or the exhibit committee may be relieved of many errands; much detailed effort in locating or check-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

ing up on commercial specialists; searching for materials for certain uses; gathering particular information. The volunteer may use the telephone to interview people, write letters, or search in books as the job may require.

A "Census of Useful People" will lay the foundation for securing desirable volunteers for future needs. See pages 201–202 in *The A B C of Exhibit Planning*—to be found in local libraries.

Again—it may be urged that experience has shown that capable people have been enlisted in exhibit construction who have had no previous contacts with the work of the agency or who had revealed no interest whatsoever in its field of work—but they *did* become interested in doing their specialty on behalf of the agency.

"Publicity as a Motive Factor"—The Health Division of the National Conference of Social Work held one joint session with Educational Publicity Division at San Francisco, June 26–July 3. "Publicity as a Motive Factor in Health Education: The Psychology of Motives; How Health Publicity Is Planned to Put Motives to Work," will be a further development of the theme considered by the Public Health Education Section of the A. P. H. A. at Chicago.

There were 19 sessions on publicity at San Francisco, with exhibits, and health workers prominent among those present.

A Panorama Exhibit—The old-fashioned panorama—even now to be found in miniature forms in toy stores—may be adapted to exhibit uses. The visitor sees an open box or simple stage front in which appears a series of pictures, with brief captions. The pictures move horizontally across the back of the stage, or perpendicularly from top to floor.

The continuity of pictures and other material will be mounted on a continuous strip of tracing cloth or other material, running over several rollers. Simpler construction will be possible by omitting the continuous feature, and winding from one roller to another, and re-winding after each showing. The winding can be by sand wheel or electric motor, or by a crank turned by a visitor or attendant.

The captions may run along with the story or may be displayed in an adjoining stage front. In this case the captions and pictures will run from top to bottom, with both "shows" mounted on the same axle or shaft so that there will be exact synchronization.

The story may be made up with pictures cut from magazines, or may be sketched by an artist or by children, or may be silhouettes. If the latter, the moving curtain should be tracing paper so that with a moderate light behind the pictures will stand out boldly.

Help the Health Editors—The editors of health journals and organs of health agencies receive many copies of pamphlets and other printed matter, usually without the information needed for intelligent comment. Is the material for sale? Is it available for free distribution? Terms? Will single copies of a report or folder be supplied as samples to health workers? Free, or for how much?

Many state or local publications are more interesting if the reader can learn the cost, the process used, the number of copies, and who received them. And frequently the reader needs to know why a publication was issued, or the result desired.

Judging by our own experience, life is too short for the editor to write for this information. Sometimes it is done, but usually we must do the best we can—give the surface information, or drop the publication into the waste basket.

Incidentally, more samples from the

field should reach the editors and the offices of the national health organizations.

Exhibit Ideas from Books and Other Sources—Many ideas to adapt to exhibit or display use may be found in books on handicraft or home amusements.

Toy stores will suggest forms which may be made over and be used to express a health idea or fact.

Window displays will include devices which may be copied or adapted.

Outside Wondering What's Inside—For school or exhibit purposes:

1. A box—set on a table or stand—with an exciting title at the top.
2. Inside are 4, 5 or 6 photographs or sketches or silhouettes or transparencies telling some health message—mounted on an axle or drum so that the visitor can revolve and see the pictures in turn.
3. The handle will project from both sides—or either side—and probably with a clutch so that it can revolve only in one direction.
4. A hole in the slanted top through which the pictures can be seen as they revolve.

In practice it may be possible to have the box larger—with 2 or 3 openings so that several people can look at a time.

RADIO

"Universal Safety Series" is presented by the National Broadcasting Co. in conjunction with the National Safety Council, running through the middle of July, on Saturdays at 7:15 P.M., Eastern Daylight Saving Time.

The dialogue, well done, is an acceptable form for broadcasting health.

Simpler to work out, and effective, is a series of questions and answers. Writing the questions, especially, offers the chance to enliven the period on the air, and, of course, the answers should not be heavy even though they may be straight statements of fact.

Questions about health and health agencies could be put to a prominent citizen who has not seen them in advance, asking the audience to determine whether or not he gives the correct answers, that is, provided you have an opportunity to present the correct answers a week later.

A group of exploded health superstitions should provide interesting material, with a good chance to bring in the reasons for modern health practices.

Something in the nature of a "stunt," like one of the above, given now and then may serve to attract new listeners, or bring back some who have tired of the routine radio talks on health topics.

POSTERS

A help toward better posters and placards is the study of the best of advertising posters. A stimulating aid in that direction is "Posters and Publicity," edited by Mercer and Guant, *The Studio*, London. It is an introductory review of poster art, and 140 pages of posters, booklet and folder covers, and a few advertisements. Many countries are represented. William E. Rudge, 475 Fifth Ave., New York, N. Y. *Cloth $4.50, paper $3.00.*

Instead of being devoted to specific information, graphically presented, many of the best posters now attempt nothing more definite than the creation of a mood in the spectator. They still hold to the old rules which have been tested by centuries of use. They remain simple summaries, direct, taken in at a glance, easily remembered. But they have in many instances dropped the insistence on a special fact to be conveyed, and prefer to make the information supplementary or incidental to the feeling. If the article advertised is represented in an atmosphere which induces friendliness in the spectator, the extra "punch" of a slogan is thought to be detrimental rather than helpful.—
New York Times, Dec. 17, 1928.

EDUCATIONAL MATERIAL

An example of coöperation by non-health movements is *Mother's First Book*, by Cora Wilson Stewart, published with the coöperation of Cleanliness Institute by the National Illiteracy Crusade, American Red Cross Bldg.,

Washington, D. C. "This book is a first reader for women who cannot read or write. It is for the teacher's use in teaching such women, and by teacher is meant any person who helps a woman to learn." It starts with the baby and what mother can do for the baby, and includes much simple health material. Those who through schools or volunteer teachers can reach illiterate women should write for a *free* copy.

The newest "baby book" is that issued by the John Hancock Mutual Life Insurance Co., Boston, Mass., "Your Baby's Care," by Susan P. Souther, M.D. Photographs and sketches are included, but never both on the same page, a colorful cover, good type and paper, *and an index.* 30 pages—all about the baby. It does not attempt to cover all of childhood. *Free.*

REQUESTS

Please send the editor your answer to this request from a visiting nurse association: "We would like to know where we can secure colored charts showing the different types of eruptions and conditions of the membranes of the throat for use in teacher groups. I am under the impression that Detroit uses something of this kind with its teachers. Can you advise me?"

Something to turn back to is "What Do You Want?" in the *Journal* for December, 1928, page 1546.

REGRETTABLE BUT TRUE

That no publication date appears on the report of a study of the health of a group of boys, issued by one of the largest of the voluntary health agencies. [Careful readers will find buried in the text the date when the study was started.]

That so many health survey reports carry no obvious indication on the cover or title page of the authority responsible for the issuance of the report, and that so frequently no address is given to which communications may be addressed.

CHILDREN AND SCHOOLS

A picture of the tuberculosis double-barred cross as formed by Health Crusaders, in "Fighting Tuberculosis and Heart Disease." Illustrated review of the activities of Tuberculosis and Health Society, 51 Warren St., Detroit, Mich. *4 cents.*

"The Health Land Herald": how a fourth grade wrote a health newspaper. *Hygeia.* Mar., 1929.

The Junior Red Cross calendar for May includes writing news stories on health and on making a plan for health during vacation.

"The straws did the trick," claims the Pine Plains Parent-Teachers' Association because "the mothers report that many of the children who would never drink milk at home are now taking it as a matter of course." Just before the lunch hour each child received a small bottle of milk, a straw and a cracker. The 4-H Club bought the straws.—Reported by Dutchess Co., N. Y., Health Association.

"Teaching Health in Schools," in *S. C. A. A. News,* 105 East 22d St., New York, N. Y., Mar., 1929, describes new project of S. C. A. A. in cooperation with Health and Physical Education Division of New York State Education Department. *Free.*

A wealth of material for school, club and home use is to be found month by month in *Safety Education,* Educational Division, National Safety Council, 1 Park Ave., New York, N. Y. *Sample free.* Every issue includes a separate poster for the classroom or the child's room at home.

Apply to the same address for "Public and School Safety Posters—1929," an illustrated catalogue. *Free.*

BOOKS AND REPORTS

The Balance of Births and Deaths—*By Robt. R. Kuczynski. New York: Macmillan,* 1928. 140 pp. Price, $2.00.

This is the first of the series of population studies contemplated by the Institute of Economics. In the present volume a comprehensive statistical survey is made of the trend of human fertility in Northern and Western Europe. Subsequent studies will deal with fertility in the remaining parts of the world for which data exist. Once the facts as to fertility are known, analyses will be made of the social causes and of the political and economic consequences of differences in fertility. In the reviewer's opinion this is by far the best statistical statement yet made of natural increase in the territory studied. Provided the contemplated studies maintain the high level of the present one, an end will shortly be made to the countless factually unsupported statements made by many ill-informed writers on population.

The data and conclusions presented and the method employed will be of value to population students, for Dr. Kuczynski, one of the outstanding statisticians of Europe, applies a method designed to show whether the populations of the European countries studied are maintaining themselves; that is, neither potentially increasing nor potentially decreasing. This method, hitherto practically unknown to Americans, will be understood by any high school student.

At present the population of Europe contains an unduly large proportion of women of childbearing age, and an unduly small proportion of children and aged persons. This age composition in turn makes for a high birth rate and a low death rate. Consequently the excess of births over deaths gives no true picture of the underlying trend. Dr. Kuczynski's method, despite its simplicity, gives as true a picture of the fundamental trend as some of the involved mathematical methods employed in this country.

So far as Northern and Western Europe is concerned the Malthusian devil, if not now chained, soon will be, according to Dr. Kuczynski's findings. At present 100 mothers give birth to but 93 future mothers. "With a fertility and a mortality as they prevail at present, the population of some smaller countries still shows a genuine growth, but the population of the larger countries, France, and especially England and Germany, is doomed to die out." While an essential change in mortality or in fertility can halt this trend, the future "depends mainly on the trend of fertility," for future reductions of mortality in the childbearing years cannot be very great.

Whereas the average number of children per woman (married and unmarried) was 4 or 5 forty years ago in all the countries studied except France and Ireland, the average in 1926 had fallen below 3 practically everywhere and was but 2.3 for the area studied.

The chapter on birth rates shows that birth rates declined continuously during the 19th century, nor did the World War essentially change this trend. By 1927 the birth rates of Denmark, Sweden, and Switzerland had fallen below that of France. Eventually, it appears, rates of the same magnitude will prevail in all the countries studied.

No public health statistician or population student can afford to be without this book, which, in addition to all its

other merits, contains a mine of carefully corrected birth rate and other vital statistical data.

JOSEPH Y. SPENGLER

Hygiene and Public Health (*Parkes and Kenwood*). (*8th ed., rev.*)—*Revised by Henry R. Kenwood, C.M.G., M.B., and Harold Kerr, O.B.E. Philadelphia: Blakiston,* 1929. 823 pp. Price, $7.00.

The present edition of this work—the eighth of the joint authorship—has been prepared by Professors Kenwood and Kerr, though the name of Dr. Louis C. Parkes, who originated the book, and for many years was its sole author, is still retained.

Few books have been before the medical public longer than this, and it is safe to say that none have retained their popularity to a greater extent. All editions have been favorably received, not only in England, but in this country, as a result of real merit.

The present edition has been brought up to date, and is a worthy successor to those which have preceded it. The only drawback for American readers is that rules and regulations concerning housing, tuberculosis, milk, etc., are those official in England. The principles, however, are equally applicable in this country.

The printing and make-up are excellent. The book can be recommended without hesitation as a text and reference for all those interested in public health.

M. P. RAVENEL

Five Years in Fargo—*Report of the Commonwealth Fund Child Health Demonstration in Fargo, N. D., 1923–1927. New York: The Commonwealth Fund Division of Publications.* 207 pp. Price, $1.00.

Public health administrators and all volunteer workers in the field of public health will welcome this excellent account of the most interesting and successful health demonstration yet reported. Those who contemplate enlisting community support for similar demonstrations or who plan any sort of progressive, forward-looking health program can do no better than study this report.

Fargo is a strategic point geographically. Wide-awake, progressive groups of practicing physicians, interested from the standpoint of scientific medicine, with the citizenship generally interested in promoting the " boost " spirit to make the " biggest little city in the Great Northwest the biggest little city in the world," must have convinced the committee of award that Fargo would be sure to win if given the opportunity for a real health demonstration.

It is refreshing to one in the public health field to note the frank appraisal of each activity in this final evaluation. Application of the rating schedule of the American Public Health Association, worked out originally on the score of 86 smaller cities, proves to the satisfaction of every student that this demonstration was well worth while. As was to have been expected, the greatest gains demonstrable by such a rating schedule occur in the special fields related to maternity, infancy, preschool age and childhood. That the general rating score should have increased from 320 points out of a possible 1,000, the year before the demonstration began, to 827 during the last year shows how largely public health results may be determined by concentrating upon these appealing programs.

To see vital statistics increase within a 5-year period from a score of 16 to 56 out of a possible 60 points in the rating schedule, communicable disease control leap from 69 to 155 out of a possible 175, prenatal service reach the maximum score allowed in the rating schedule, infant service approach the full allowance by reaching 69 out of 75, preschool service acquire the full ap-

praisal value of 50 points, school health service score 141 out of 150 points, and the laboratory activities reach the maximum rating during the last two years of the demonstration, should convince anyone of the value of the experiment..

The per capita cost of $1.59 is well within the financial reach of any forward-looking community. Those who figure in dollars and cents, and who question whether a well worked out health program may be fully sold to a community, need not go beyond pages 49 and 50 to be convinced of the monetary value of extensive health activities properly demonstrated.

The City of Fargo annually increased its health funds from $20,663 in 1922, and $24,132 the year the demonstration began, to $36,000. At the end of the demonstration when Fargo took over all activities, the total budget for health activities was $40,600.

The growing interest shown by the teachers and the mothers of school children examined, and that kept up by the various community service clubs and the public press, all tend to prove in a most practical way that the community realized its full responsibility, and heartily joined in a sort of co-partnership with the director of the demonstration, his staff and the medical profession in assuring success.

This little volume should be in the library of every public health administrative officer and every volunteer health organization.

B. FRANKLIN ROYER

The Facts of Modern Medicine. *A Simplified Statement of Established Knowledge on Medical Subjects, with Reference also to Certain Current Misconceptions—By Francis W. Palfrey, M.D. New York: Appleton,* 1929. 490 pp. Price, $5.00.

As stated in the preface, the author had two objects in the preparation of this book: to lessen the gap between the knowledge of medicine common to the general public and that of the medical profession; and to give to students a preliminary view of medicine drawn in a broad outline, but with its parts in true perspective. While we doubt the wisdom of this dual purpose, we believe that the book will come as near to fulfilling its object as possible.

As a book for the layman, it is excellent—accurate in detail and well written —perhaps a little bit too smoothly to hold the reader's attention.

The illustrations are good, the microphotographs especially so, though we cannot help wondering what the average layman will make out of some of them. Probably they are put in for the beginning medical student. An excellent crayon portrait of Osler, by Sargent, faces the title page.

The printing and general make-up of the book are excellent.

M. P. RAVENEL

Animal Parasitology—*By Robert Hegner, Francis M. Root and Donald L. Augustine. New York: Century,* 1929. 731 pp., 280 figs. Price, $6.50.

This book gives the gist of the instruction in protozoölogy, helminthology and medical entomology as offered at the School of Hygiene and Public Health of Johns Hopkins University, and provides an adequate and comprehensive single textbook in parasitology which utilizes some of the large amount of valuable material accumulated by the International Health Board and other agencies of the Rockefeller Foundation.

The attempt to cover so large a field within the compass of 600 pages is disastrous, in that illustrations are of necessity reduced; the text becomes more or less a thinly clad skeleton; and the proportion required for the necessary commonplace matter is large. The attempt to include the parasites of the domesticated animals is very incom-

pletely carried out, a few of the better known being rather superficially treated. This information is of value to students of biology, but is quite inadequate for veterinary purposes. The book has only about half as many pages and illustrations as the section dealing with animal parasites in the well-known *Précis de Parasitologie,* of Brumpt, which treats only of human parasitology.

The work falls into three equal sections. The first, on protozoölogy, is by Professor Hegner of Johns Hopkins School of Hygiene and Public Health, the second by Professor D. L. Augustine of Harvard Medical School, and the third by Professor F. M. Root, a colleague of the first named author. The section on protozoölogy is a condensation of the author's books *Human Protozoology* and *Host-Parasite Relations,* with some additions which make the treatment somewhat more comprehensive.

The second part is less satisfactory in its treatment of the Platyhelminthes than in that of the Nematheiminthes, where much new material is assembled concerning hookworm, hookworm surveys and campaigns. There is little new in the way of illustrations, old friends which have appeared in every textbook since the days of Leuckart still adorning the pages of this latest work, whiie some of the new ones are no improvement over the old. The chapter on methods will be very welcome to all public health laboratory workers.

The closing section on medical entomology covers a large field and has been handled with skill. There are new and significant illustrations, carefully worked out keys, clean-cut accounts of measures for control and prevention of insect vectors, and discussions of the relations of insects to various diseases.

The bibliography is extensive, perhaps needlessly extended, and printed in larger type than necessary. A more careful handling of the typography, size of illustrations and set-up would permit a considerable gain, either by reducing size and cost, or increasing the text and illustrations without increase of pages.

This book will be of particular value to technicians in public health laboratories and as an important work of reference for public health workers. Preventive medicine has made some of its most inspiring and noteworthy contributions through research in parasitology. Every worker in this field should review the achievements in this field as presented for inspiration, and face anew the problems which he will find assembled in this comprehensive, authoritative and up-to-date work. C. A. KOFOID

What Everyone Should Know about Eyes (*National Health Series*)—*By F. Park Lewis, M.D. New York: Funk & Wagnalls,* 1928. 70 pp. Price, $.30.

Much valuable information for the layman is crowded into this little book. The mechanism of sight is first explained, particular attention being directed to near-sightedness and squint. Reasons for, and methods of, examination are so outlined that the reader may visualize the procedure.

Part II considers trachoma, birth infections, accidents and injuries, showing how our knowledge of preventive measures has been increased.

The author has recognized the necessity of education in regard to diseases affecting the optic nerve, cataract, iritis, and glaucoma; also pointed out the changes that take place in the eye in old age.

The final chapter on hereditary eye defects answers some questions and provokes thought. Dr. Lewis is to be commended for presenting useful scientific information in popular terms, thus rendering admirable service to the cause of education. CONRAD BERENS

Why Not Grow Young? or Living for Longevity—*By Robert W. Service. New York: Barse*, 1928. 266 pp. Price, $1.50.

Youthful Old Age. How to Keep Young—*By Walter M. Gallichan. New York: Macmillan*, 1929. 236 pp. Price, $2.50.

We confess frankly that we are tired of books written by non-medical men who think that some fad or another has saved their lives and preserved their health. Public health is popular, and we cannot help suspecting that the financial element is back of some of the apparent desire to spread alleged information.

Both of the books mentioned above are well written—that by Mr. Service in a breezy, robust style, which makes it very attractive, that by Mr. Gallichan in a more conservative and philosophical style, which, however, is pleasing.

One cannot but be astonished at the cocksure tone which both exhibit. Verily, verily, mortals rush in where angels fear to tread. Even the question of blood pressure presents no difficulties to Mr. Service. His fad is Royat, and he even goes so far as to make the absurd statement that physicians will not endorse Royat because their business is to cure by drugs rather than nature, and knowing what Royat will do, "they will lose a profitable patient." He gives 100 "do's and don't's" for the middle aged man, which compels one to wonder why he should be more of a fool before 50 than after, as far as the preservation of health goes.

Mr. Gallichan is an author of parts, proudly claiming 52 volumes for his 67 + years. He has developed a philosophy of life which is attractive. If his knowledge equalled his philosophy, we would have no fault to find. He is evidently a disciple of Sir Arbuthnot Lane.

Both authors have read widely without the fundamental training necessary for understanding. Both of them attribute their health to their fads instead of to a God who has been kinder to them than to the public in allowing them to continue their writing.

We cannot but remember the story of Bishop Berkeley, of whom it was said "To Berkeley every virtue under heaven." In spite of his learning, to him tar water was a panacea for every ill—mental, spiritual and physical. As Oliver Wendell Holmes put it, he was a great and good man, but held two very peculiar ideas—that the material universe and all it contained was nothing, while tar water was everything. As expressed by the same beloved physician, his life illustrated a point which Messrs. Service and Gallichan might well take into account:

> Berkeley himself afforded a remarkable illustration of a truth which has long been known to the members of one of the learned professions, namely, that no amount of talent, or of acquirements in other departments, can rescue from lamentable folly those who, without something of the requisite preparation, undertake to experiment with nostrums upon themselves and their neighbors.

M. P. RAVENEL

Proceedings of Sixth Annual Short School Texas Association of Sanitarians. *Assembled at San Antonio, Texas, November 7–10, 1928. Austin: Texas Association of Sanitarians.* 188 pp. Price, $1.00.

These proceedings contain the usual amount of interesting and instructive reading. Health education receives the largest proportion of space and includes discussions of such subjects as "Coöperation in Public Health by Veterinarians" and "The Plumber and His Trade."

Communicable diseases and foods and drugs are allotted sections of the journal. In the first of these there is an able paper on the effect of rat extermination on health and economy.

Fifteen pages are given over to water sanitation, and following that various

phases of sewage treatment are discussed. In the later section, Mr. Guzman of the University of Mexico outlines briefly sewage disposal conditions in his country.

In the back of the book 40 pages are needed to give the public health and welfare organizations and allied groups in Texas; lists of the dairies, creameries, licensed veterinarians, public health nurses and master plumbers; and a proposed state plumbing code.

ARTHUR P. MILLER

Advice to the Expectant Mother on the Care of Health—*By F. J. Browne, M.D. Edinburgh: E. & S. Livingstone,* 1928. 48 pp. Price, $.50.

The benefits to be expected from regular physical examinations during pregnancy are directly and simply stated. What might be termed the standard information on prenatal hygiene, the common disorders of pregnancy, and the general care of the new-born baby are concisely given. The symptoms and importance of the more serious disorders are clearly explained.

This small book gives in the most orderly fashion and in easily understandable language all that is important, without unessentials. C. E. HAYES

Protozoology. *A manual for medical men—By J. G. Thomson and Andrew Robertson. New York: Wood,* 1929. 376 pp., 4 col. pl., 220 figs. Price, $11.00.

This manual of protozoölogy differs from the numerous others in this field in that it is written by medical men for medical men, but without discussions of therapy or epidemiology. It deals with malaria (64 pp.), coccidiosis (16 pp.), babesiasis (4 pp.), amebiasis (38 pp.), intestinal flagellates (26 pp.), leishmaniasis (21 pp.), trypanosomiasis (29 pp.), spirochetes (12 pp.), syphilis, yaws, etc. (11 pp.), leptospirosis (7 pp.), and other minor protozoan infections of man. Epecially valuable are the discussions of the pathologies of the various protozoan infections, notably that of malaria, in which field the senior author is a world authority.

The authors have had access, through their connections with the London School of Tropical Medicine, to large collections of autopsy material and have rendered a great service to protozoölogists and medical men alike in their judicious and ample use of this illustrative material and their comprehensive discussions of it. There is a valuable chapter on fallacies and puzzles in blood examination, and another on common objects in stools other than protozoa. The chapter on coccidiosis has new material showing sources of contamination in human feces from the coccidia of the sardine.

There are many new illustrations. The four colored plates are excellent, but many of the photomicrographs exhibit poor technic in photography or reproduction, or both. Some of the text figures are quite crude, with little attention to cytological detail, and are unduly enlarged in many instances, thus adding materially to the cost of an already quite expensive book. There is a good chapter on the various technics of fixing, staining and preparation of culture mediums, an etymological glossary and a full index. C. A. KOFOID

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Typhoid Fever—The annual compilation of municipal typhoid fever death rates by sections. The southern states, as usual, are higher than elsewhere in the country, but their rates are lower than for previous years. The record as a whole is a good one. Nine cities had no deaths.

Typhoid in the Larger Cities of the United States in 1928. J. A. M. A., 92, 20: 1674 (May 18), 1929.

Diphtheria Death Rates—The same statistical comparison of municipal experience in relation to diphtheria. Eleven cities had death rates of 2.0 or less (Grand Rapids 0.0) and 10 had rates between 20.0 and 14.6. Food for much thought, speculation and mutual recriminations.

——. Diphtheria Mortality in Large Cities of the United States in 1928. J. A. M. A., 92, 21: 1759 (May 25), 1929.

Antarcesis—Suggested by the author to designate protective power against disease born of normal or balanced physiological activity as distinguished from immunity resulting from invasion. The paper is about variations in incidence of poliomyelitis, and is a good one.

AYCOCK, W. L. A Study of the Significance of Geographic and Seasonal Variations in the Incidence of Poliomyelitis. J. Prev. Med., 3, 3: 245 (May), 1929.

Watershed Protection Practice—A symposium on protecting potable water supplies by five local representatives, and from the standpoint of the State Board of Health. Very interesting for those who are faced with this vexing problem.

BURT, JOHN, *et al.* Watershed Protection Practice in California. J. Am. Water Works A., 21, 5: 589 (May), 1929.

Anti-Tuberculosis Work—Sound comments on a quarter century of tuberculosis preventive measures, with emphasis on doctor-patient relationships.

DEVINE, E. T. The Quarter Century Health Crusade. Survey, 62, 4: 229 (May 15), 1929.

Care of Chronic Cases among Children—Telling of the measures taken for the care of chronically sick children in Boston. One-sixth of all chronic cases are children.

EAVES, L. Children Who Are Chronically Sick. Survey, 62, 4: 241 (May 15), 1929.

Camp Sanitation—Points are listed which should be observed in inspecting summer camps.

FELSEN, J. A System of Classification of Summer Camps. J. A. M. A., 92, 21: 1789 (May 25), 1929.

Medical Student Health Examinations—How Harvard medical students are impressed with the value of health examinations. Each student receives at least four examinations and gives at least two to other students. They become interested in the follow-up of their own cases and try to keep fit. Is it too much to expect that this so evidently sensible scheme will be adopted in all medical schools?

FITZ, K. *Periodic Health Examinations* as a Part of a Medical Student's Curriculum. J. A. M. A., 92, 20: 1645 (May 18), 1929.

Anti-Malarial Measures—A dusting outfit is described by which Paris green mixed with lime may be applied effectively to waters in which anopheline mosquitoes breed.

LE PRINCE, J. A. Development of a Power Dusting Device for Applying Paris Green as an Anopheline Larvicide. Pub. Health Rep., 44, 17: 1001 (Apr. 26), 1929.

Tuberculosis Skin Test—The simple and reliable percutaneous tuberculin reaction described is suggested in preference to other procedures because it is easier to do and causes less discomfort to the patient.

LOVETT, B. R. The Percutaneous Tuberculin Reaction. Am. J. Dis. Child., 37, 5: 918 (May), 1929.

Rural Health—Tables are given showing increase by counties in rural health administration. Despite the increase, more than 77 per cent of the rural population has no adequate health service.

LUMSDEN, L. L. Extent of Rural Health Service in the United States, 1925–1929. Pub. Health Rep., 44, 20: 1192 (May 17), 1929.

The Year in Public Health—Some of the high spots in 1928 are reviewed; the activities of the federal health service, the several funds, and progress in biologic and economic research are included.

MOORE, H. H. Progress in Public Health and Medicine, 1928. New England J. Med., 200, 20: 1045 (May 16), 1929.

Etiology of Poliomyelitis—Evidence is offered supporting the view that a streptococcus (as suggested by Rosenow) cannot be regarded as identical with the filtrable virus of poliomyelitis.

OLITSKY, P. K., *et al.* Relation of Streptococci to the Spinal Fluid of Experimental Poliomyelitis. J. A. M. A., 92, 21: 1725 (May 25), 1929.

The Decline of Nations—One of those vague, "What causes that?" dissertations evidently so dear to the heart of the Britisher. All about the troubles that came to Greece and Rome. The author casts a worried eye to America and shakes his head over us. Wealth, luxury and vice are prominently mentioned.

OLIVER, THOMAS. Some Factors Which Have Made for the Decline of Nations. Med. Off., 41, 19: 201 (May 11), 1929.

Leprosy—The so-called leprosy bacillus is an actinomyces, a soil organism of wide but irregular distribution. Leprosy is primarily a soil infection presumably through wounds. These conclusions will change our conception of rational control measures, if they are generally accepted.

WALKER, E. L. Some New Aspects of the Etiology and Endemiology of Leprosy. J. Prev. Med., 3, 5: 167 (May), 1929.

Less Sugar Instead of More—A delightfully mild mannered slap at the propaganda of the sugar and candy manufacturers. Should be read by every sanitarian.

SHERMAN, H. C. The Problem of Sweets for Children. Child Hyg. Bull., 5, 3: 65 (May), 1929.

Diphtheria Prophylaxis—An unfavorable report on the use of Larson's combined diphtheria and scarlet fever toxins ricinoleated. The author sees little advantage in toxoid over toxin-antitoxin mixture. In a following paper the author reports no results in the treatment of 14 cases of measles with Degkwitz's animal immune serum.

SILVERMAN, A. C. Immunization with Modified Toxin. Am. J. Dis. Child., 37, 5: 957 (May), 1929.

Detecting Scarlet Fever Carriers—A rapid and simple laboratory method is suggested for the detection of scarlet fever carriers by means of an opsonic test.

TUNNICLIFF, R., and CROOKS, T. T. The Healthy Carrier in Scarlet Fever. J. A. M. A., 92, 18: 1498 (May 4), 1929.

Influenza Incidence Index—Attack rates from influenza studied in sample populations in 11 representative cities showed a range of from 11.3 to 17.9 per 100 persons canvassed, in 1928–1929. This was about half the 1918 rate.

VELDEE, M. V. Morbidity in the Influenza Epidemic of 1928–1929. Pub. Health Rep., 44, 19: 1133 (May 10), 1929.

Sunlight and Bacteria—A well planned demonstration of the bactericidal properties of sunlight, direct and indirect, and the component light rays. The application of the facts demonstrated is discussed. A very useful lesson.

MEADER, F. M. Sunlight as a Disinfectant. City Health (Detroit), 13, 3: 3 (Mar.), 1929.

Control of Pneumonia—Valuable summarization of the status of serum therapy in pneumonia and a suggestion of the inclusion of vaccine therapy as well in the treatment of the disease.

ZINSSER, H. An Immunological Consideration of Pneumonia and a Discussion of the Rational Bases for Vaccine Therapy. New England J. Med., 200, 17: 853 (Apr. 25), 1929.

ANNUAL REPORT OF THE DEPARTMENT OF HEALTH, BUFFALO, N. Y. Year ending December 31, 1928.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Fort Worth, Tex.—A health and welfare survey and appraisal of the city of Fort Worth by the Director of Public Health and Welfare is a document of 140 mimeographed pages of unusual interest to health and welfare administrators. The new city appraisal form has been utilized for the health survey, and on a similar basis, an appraisal of welfare work has been developed. The latter form is the first of its kind which has come to the attention of the reviewer.

This city of 191,448 population reports a birth rate of 15.5, a death rate of 10.5 and an infant mortality rate of 77.9. There are 12 hospitals and clinics in the city with 708 beds, 585 for white, 101 for colored and 22 for day patients. Exclusive of the Independent School District, there are 41 colleges and schools of different character in Fort Worth. There are about 22 agencies doing health and welfare work. There are 201 white physicians, not including the 4 doctors in the Department of Public Health and Welfare, and 11 colored physicians.

About 85 per cent of the milk supply is pasteurized. The major portion of the milk is delivered in the city within a few hours after production, within a radius of 50 miles of the city. There are approximately 10,066 cows producing 19,333 gallons of milk daily. Some 1,519 food establishments are under supervision.

For the purpose of administration and operation, the Department of Public Health and Welfare is divided into 6 separate divisions or bureaus: administration, communicable disease control, nursing, inspection, laboratory, and welfare. All free clinics and dispensaries, maternity hospitals and other hospitals maintained within the city are under the supervision of the director of this department.

Following his recommendations regarding future program, the director makes a plea for unity of purpose.

> The health and welfare of a community should not be bartered or maligned but should be upheld by all who are capable of thinking. "Unity of purpose" should be the watchword, and everyone should carry the message home to some one so that when we pass on we may look back upon an accomplishment that lives on and on. If, in surrendering the personal equation, we may help to serve some child who is unable to think for itself, is it not far better for the community and for our own selves? My earnest plea is that everyone doing any character of work for the promotion of health and welfare unite his or her efforts for a common achievement.

New Mexico—The fifth biennial report for 1927–28 carries on the inside of the front cover 21 items on, "What the New Mexico State Bureau of Public Health Does for You," all at a cost of 7½ cents per person in taxes. There is a table of contents at the front and an alphabetical index at the back. The inside of the back cover lists the bureau personnel and the outside gives an organization chart of the Board of Public Welfare with the bureaus of public health and child welfare.

A comprehensive campaign for complete registration of births and deaths was worked out in coöperation with the U. S. Bureau of the Census, the U. S. Children's Bureau, the American Public Health Association and the Rockefeller Foundation, to be started in the fall of 1928.

Malaria cases appeared in one county in large numbers and led to the introduction of active control measures. Paris green was regularly dusted on all mosquito breeding pools and ditches

throughout the settled portion of the county. Regular checks indicated a large reduction of mosquitoes. Quinine was also distributed to cases and carriers unable to provide it for themselves.

For several years, regular health courses have been advocated in the normal schools. Through the coöperation of the state and national tuberculosis associations, a trained teacher was supplied to two of the normal schools in the summer of 1927. As a result, permanent courses have been established and will doubtless be enlarged. The State University has created a Department of Hygiene with a comprehensive plan for development. The health department maintains a loan library of books and periodicals.

Vermont—An outbreak of rabies early in 1927 and the flood of November of that year receive special consideration in the department of public health report for the biennial period ending December 31, 1927. From February to August, 21 dogs, 4 cows, 1 calf and 3 sheep were found to have rabies, but no human cases occurred. Prompt control measures were exercised by the Department of Agriculture and Department of Health and in March an act relating to the control of rabies was passed by the legislature.

As a result of the flood, some 5,500 persons received typhoid inoculation. It is noteworthy that diseases due to exposure and exhaustion, such as colds and pneumonia, did not occur to any considerable extent. "It is with a considerable degree of pride that we report that not a single case of typhoid fever resulted from the flood, nor was there any epidemic of any kind."

Vermont has been a fruitful field for the study of poliomyelitis and its aftercare. The epidemic of 1914 with 306 cases forcibly called the attention of both physicians and laymen to the disease, and it is an unusual case which is not brought to the attention of the Department of Health within a few hours after being seen by the physician. All cases are then followed up by the research worker and later by the aftercare nurses. "A situation has therefore worked out which offers coöperation on the part of the profession and an interested expectancy on the part of the people." During 1927, 954 patients were under supervision, 183 being new admissions.

Colorado Springs, Colo.—This is another health report attractively illustrated with photographs. Improvement in the water and milk supplies over previous years is noted. The average bacterial count of the milk of 20 dairies producing raw milk during the year was 10,065; the average for 8 producers of pasteurized milk was 14,918.

Three cases of diphtheria, with no deaths, is the record of this city with a population of 36,000. Of the 150 deaths from tuberculosis, only 4 were among persons who contracted the disease locally. There was a crude death rate of 18.03, but the resident death rate, exclusive of deaths from tuberculosis contracted elsewhere, was 11.8. An enlightening analysis of tuberculosis and total deaths is made according to occupation and birthplace. The health department expenditure was $26,176.

Hygienic Institute, Ill.—Printed on soft paper in good sized type, easily read, with a few appropriate photographs of health and hospital buildings, with carefully prepared statistical tables and descriptive text, this report is a credit to the department. The population of the three communities served, La Salle, Peru, and Oglesby, is 30,000, and the budget for the fiscal year ending June 30, 1928, was $38,000. The personnel consists of a medical director, a bacteriologist and chemist, a sanitary

officer, a chief nurse, six staff nurses, a stenographer-clerk, and a general service man. The Institute does the Metropolitan bedside nursing work and in addition offers hourly bedside nursing work to the community. This organization maintains a medical library for the use of local physicians, partially supports a hospital for the isolation of communicable diseases, and conducts a series of infant welfare and other clinics.

An infant mortality rate of 61, a tuberculosis death rate of 34 and a general death rate of 9.2 are noted. There were no cases of diphtheria reported during the year in this entire district. An appraisal of health service has been made for four years and shows a noteworthy increase in attainment from 456 in 1924–25 to 709 in 1927–28. The report concludes with a classified financial statement.

San Jose, Calif.—This city, with an estimated population of 62,750, reports for 1928 a birth rate of 12.7, a death rate of 11.6, and an infant mortality rate of 44.3. There were 669 births attended by physicians, 93 by midwives, and 5 by others. Detailed statistical tables and graphs indicate progress in the reduction of the death rate. "The broad vision of the manager and members of the city council in allowing an increased yearly budget made possible such advancement."

Prenatal cases made 256 visits to clinics and received 599 home visits by the health department. There were 1,349 visits of infants to clinics and 1,626 home visits by nurses. Preschool children made 2,163 visits to clinics and received 3,040 home visits.

Under popular health instruction it is noted that a bi-weekly postcard bulletin is sent to the press, physicians, schools and health workers. The expenditures of the department amounted to $34,469, but there was an additional revenue from inspections, permits and vital statistics of $15,231. Attractive photographs add interest to this annual health department report.

Detroit, Mich.—The greatly increased number of persons reached by the health department through printed educational material and health talks is cited as one of the outstanding developments of the year 1928. This wider distribution of literature has been made possible through the coöperation of insurance companies, milk producers and retail stores. An attempt has been made by the use of letters to keep in closer personal touch with physicians and parents. Many posters have been used. Coöperation with the newspapers has been excellent, with more feature stories, interviews and notices than heretofore.

During the year 1928, the tuberculin testing of all cows on farms supplying milk to Detroit has been carried out. The lowest typhoid fever death rate (1.0), and a decrease in deaths from violence and from automobile accidents are also noted. The general death rate was 11.6 per 1,000 population. Organic heart disease and the pneumonias continue to lead other causes of death by a wide margin.

There are 9 companies supplying bottled water for domestic use, and their plants are periodically inspected. During the year 15,729 food handlers were examined, 10,074 by private physicians and the remainder by the health department. Less than one-half of one per cent were found to be afflicted with a communicable disease.

The psychological effect on the food handler of examination and instruction is important as it keeps in the foreground of his consciousness the importance of his place in the prevention of disease. To emphasize this phase, simple, practical talks are given to food handlers at the time of examination.

The report contains helpful information regarding the work in communicable disease control and child hygiene.

The major emphasis of the school health service during the first half of the school year was placed on diphtheria prevention. The entire medical staff, augmented by extra physicians, devoted its full time to the giving of toxin-antitoxin and the Schick test. Also, more preschool children were reached than previously. The results of prenatal clinic service are indicated by the infant mortality rates. Infants of mothers attending within 16 weeks of pregnancy had a mortality rate of 43.6; those attending within 16–28 weeks, 44.7; and those attending after 28 weeks, 71.4.

"If the prenatal clinic rate had obtained throughout the city, there would be 540 babies alive today who have died."

Hartford, Conn.—This city of 172,288 reports a resident death rate for 1928 of 10.4, a tuberculosis death rate of 71.9, a diphtheria rate of 8.7, a heart disease rate of 208, and a cancer death rate of 105. A birth rate of 18.6 and an infant mortality rate of 62.36 are recorded. It is noteworthy that all of these rates are based on deaths allocated for residence. Expenditures of the Department of Health amounted to $173,412.

There were no deaths from scarlet fever in 1927 or 1928. Eight persons with fever gave the agglutination reaction for Malta fever. In all but one, there was a history of continued use of raw cow's milk from herds known to be infected with contagious abortion. The isolation hospital cared for 59 per cent of the diphtheria cases and 45 per cent of the scarlet fever cases.

Approximately 50 per cent of the resident births occurred in hospitals. Health education work for infants and preschool children is carried on in conjunction with the general health program of the Board of Health and the Visiting Nurse Association. A total of 7,059 children were under observation during the year, with a record of 19,000 visits to health stations and 39,000 home calls by nurses in their behalf.

That the records of vital statistics shall each year be a little more accurate and complete than those of previous years is the aim of this department. The checking of each document received against all previous records having any bearing on it is an important part of this work. The careful study of the causes of death as given by physicians often results in securing information which quite changes the classification of the cause of death.

Palo Alto, Calif.—An interesting, comprehensive report of 19 pages for a city of 12,500! In 1928 there was recorded a death rate of 8.4, the average age at death being 62.4. There were 138 births to residents. For the last 3 years the infant mortality rate has been below 30, and the average for the last 10 years is 42.7, and for 1928, 29.0. There were no cases of smallpox or typhoid fever, and only 5 cases of diphtheria.

After July 1, 1929, it is stated that all milk will be obtained from tuberculin tested cows and the only raw milk allowed will be guaranteed raw and certified.

Health authorities are almost unanimous in believing that the only safe milk is a properly pasteurized milk. Intelligent dairymen are quick to see that their very existence depends upon a safe milk and readily coöperate in improvements such as these.

The health department appropriation amounted to 99 cents per capita.

Newport, R. I.—Newport's health department experienced no staff changes during 1928. The "permanent" population, estimated, was 28,687, with 5,000 additional during the 4 summer months. Deaths from all causes numbered 342, of which 29 were among infants. For 17 months, there have been no cases of diphtheria—a commendable record. A clinic for immunization of preschool children is held each spring. It is in-

teresting to note in the financial statement that $20,262 was expended in 1928, and $29,318 in 1917. The larger expenditure in 1917 is stated to have been due to a diphtheria epidemic for which $17,000 above the usual amount was appropriated.

For the most part the milk supply is obtained from sources within 10 miles of the city. This annual report marks 10 years of enforcement of a regulation permitting the sale of only certified or pasteurized milk. The average bacteria count of pasteurized milk was 27,250, and that of certified milk, 11,981, during the year. It is calculated that local consumers expended $842,404 for milk and cream, on the basis of an average daily consumption of 12,131 quarts of milk and 487 quarts of cream in 1928.

Palestine Survey Commission—The reports of the experts submitted to the Joint Palestine Survey Commission make an impressive volume of 741 pages. The last 204 pages are devoted to a study of the hygiene and sanitary conditions of Palestine in general, with special consideration of the health and well-being of the Jewish people, for whom health work is done by a variety of agencies.

The surveyors found Palestine a country of promise and possibilities so far as health is concerned. It is now in the stage of privy sanitation which all pioneering countries pass through during the course of modernization. It is stated that the problem of public health is largely economic, for the building of adequate water supply systems, the installation of good sewerage and drainage, and the establishment of modern sanitary improvements are very expensive. Public health education will require time and patience and will involve changing the sanitary habits of a large proportion of the entire nation. At present about 15 times as much money is spent for education, and 5 or 6 times as much for police protection, as for health.

Admirable work has been done in Palestine in the prevention of certain infections, notably malaria and trachoma. Prenatal and infant welfare services conducted by the Hadassah have reduced the maternal and infant mortality. It is believed that the next attack should be upon typhoid, dysentery and the diarrheal infections, because they are prevalent and preventable.

The surveyors were favorably impressed with the organization and personnel of the health department. They state that an able group is carrying on the best traditions based on English practice.

Palestine is divided into four geographic districts, each in charge of a medical officer of health, who in turn has assistant medical officers in the various subdivisions.

There are approximately 600 licensed physicians, with over 400 Jewish physicians, or a ratio of 1 to every 400 Jews in the land. Over 1,300 women are registered as midwives. The first regulation for the training of nurses was issued in 1919, since which time over 100 have completed their training and passed examinations for nurses' certificates.

The report emphasizes the need for increased funds for the extension of sanitary facilities and health personnel, together with the possibility of extension of governmental activities to include certain phases of work now carried on by voluntary agencies. The program of Hadassah, the voluntary medical organization, if adequate funds were available, might include expansion of hospital and clinic work, public health nursing and home visitation, public health education and the promotion of mental hygiene.

LEAGUE OF NATIONS NEWS

C.-E. A. WINSLOW, DR. P. H.

THE fourteenth session of the Health Committee was held at Geneva from May 2 to 8, with the president of the committee, Dr. Madsen, in the chair. Two of the three American members, Surgeon General Cumming and the writer, were in attendance.

The report of the medical director indicated satisfactory progress along routine lines. The service of epidemiological intelligence including the operation of the Singapore bureau is proceeding satisfactorily and, aside from the epidemic of mild influenza which has recently prevailed in Europe, there is nothing unusual to note in this field. A peculiarly virulent form of diphtheria has prevailed in several European countries against which ordinary doses of antitoxin are useless. In Denmark, dosage of 500,000 units has been used with success. Sanitary interchanges on industrial hygiene and on rural hygiene have been held this spring and a joint commission of the Health Organization and the International Labour Office has made a study of the relations between sickness insurance organizations and public health services in Germany and Austria. It is planned later to arrange for interchanges dealing with the questions of milk supply, sanitary engineering and housing, and provision will be made in 1930 for a general sanitary interchange in France. A study tour dealing with malaria will be made in India beginning this August.

It will be of interest to Americans to note that an entire morning of the Health Committee sessions was devoted to reports by Surgeon General Cumming and the writer on the survey and appraisal methods used for the stimulation of public health procedure in the United States and on the work of the recently organized Committee on the Cost of Medical Care.

The Health Committee voted that an account of the survey method and of the studies of the Committee on the Cost of Medical Care should be included in the publications of the Health Organization, and the medical director was invited to prepare a report on methods employed for the appraisal of public health activity and, in collaboration with the school of hygiene and health administration interested, to collect and analyze information concerning the work of health centers and other similar activities in Europe.

Reports were presented of the commissions engaged in preparing for the forthcoming revision of the *International List of Causes of Death* (in which Haven Emerson, M.D., has played a prominent part). The schedule which will be presented for consideration at the final meeting next fall includes a full list of 155 titles, an abridged list of 86 titles and a third still shorter list which may be adopted by various governments as alternatives.

The Cancer Commission presented a particularly valuable report of a comparative study made by the institutes of radiology in Stockholm and in Paris, and the Women's Clinic at Munich in regard to the radium treatment of uterine cancer. The comparison of different methods adopted by these three institutes has proved of great value, and the results obtained are distinctly encouraging.

A commission on child welfare made a preliminary report summarizing in-

tensive studies on over 5,000 infant deaths and over 2,000 stillbirths in selected districts in Austria, France, Germany, Great Britain, the Netherlands and Norway, and similar studies are now under way in certain South American countries. The European districts covered vary from a district in Norway with an infant mortality rate of 35 to one in Austria with an infant mortality rate of over 200, and a comparison of the causes of death in relation to social, economic, and medical factors in these various districts promises to prove most illuminating.

The most important matter which came before the Health Committee is the program for reorganization of the health service of Greece. The Greek government a year ago invited the Health Organization to prepare a comprehensive program of health administration, and during the past winter and spring an exhaustive survey has been made in which Dr. Haven Emerson and Dr. Allan J. McLaughlin took part. On the basis of this study a program has been prepared for the development of a school of hygiene, and technical services of malaria control and sanitary engineering, and for the gradual development during the next five years of full-time health services ultimately covering the entire country. In each prefecture there will be a health center equipped with health visitors and sanitary assistants grouped about larger centers for laboratory and technical service. Detailed plans have been prepared for the training of personnel, and salaries and conditions of appointment will be such as to make the staff of the new service a *corps d'élite*. The program has the heartiest backing of M. Venizelos, and steps will be taken to put it into force in the immediate future.

NEWS FROM THE FIELD

SCHOLARSHIP IN UNIVERSITY OF MISSOURI

THE Woman's Auxiliary to the Missouri State Medical Association, at its recent meeting, May 14, 1929, founded a scholarship to be awarded to the student graduating from the School of Medicine of the University of Missouri who is deemed most worthy on account of scholarship, character, and financial necessity. The scholarship will carry $500 annually, and will be awarded for two consecutive years to the same student.

No particular line of work has been prescribed for those students to whom the award is made, though the fundamental object is the promotion of public health work, and it is hoped that those obtaining the scholarship will interest themselves in this specialty.

MASSACHUSETTS GENERAL HOSPITAL TO CUT MEDICAL COSTS

THE medical staff and trustees of the Massachusetts General Hospital have agreed on a plan whereby hospital charges and medical fees will be set at rates well below those now paid by patients in the private rooms, and yet sufficient to cover the cost of hospital care and compensate the physicians and surgeons. This will almost cut in half the usual bill for hospital sickness of a middle class patient.

Dr. Michael M. Davis, the Director of Medical Services of the hospital, says:

> . . . At present a 2-weeks' stay of a patient in the private pavilion of the Massachusetts General Hospital with a surgeon's fee would usually cost $250 or more. . . . If a patient stayed the same period in a ward bed and paid the full ward rate, it would cost him only about $60 and the doctor's work would

be done as charity. The large majority of Americans do not want charity, yet they are unable to pay the usual high charges for private rooms and private physicians. The Massachusetts General Hospital Plan fills the gap.

This new plan will be executed in the Baker Memorial Building, a special section of the hospital, now under construction. It will have 300 beds. There will be private rooms and provisions for 2 or 4 patients in the larger rooms. Rates, including all nursing service, will be from $4 to $6.50 per day.

ROCKEFELLER FOUNDATION RECORD

SINCE May 22, 1913, the Rockefeller Foundation has paid out from income and principal a total of $144,189,400. Most of this has been spent on the training of doctors, health officers, and nurses, the creation or strengthening of institutions of medical or public health education, building up of official health organizations, promotion of field research and the demonstration of new methods.

Temporary anti-hookworm campaigns in the United States and in many other countries have been broadened into permanent official rural health organizations. Malaria has been studied more fully and methods of control worked out at home and abroad. Yellow fever has been forced to retreat from Mexico and Central America and from Northern South America, until it is now found only in Brazil and West Africa. A wartime anti-tuberculosis organization built up with Foundation aid in France has been wholly taken over by the French and is being incorporated into a general public health service.

The sum of $29,000,000 has been spent for the creation of various schools and institutes of public health; for the strengthening of medical schools in many parts of the world from London to Singapore. This does not include the building, equipment and support of the Peking Union Medical College, and aid to hospitals and the premedical sciences in China.

Up to December 31, 1928, 3,187 fellowships have been granted, to representatives of 58 countries. The international significance of these may be inferred from the fact that 1,383 of these fellows pursued their studies in countries other than their own.

SHOCK-PROOF X-RAY APPARATUS

A NEW type of x-ray apparatus, which is completely insulated in oil and with all high-voltage wires completely eliminated, has been announced by the Victor X-Ray Corporation, with the installation of the first of these machines in the Neurological Institute, New York, N. Y.

Virtually any part of a patient's body may be x-rayed from any angle without moving the patient. Manipulation of the device to the patient's position replaces the shifting of the patient's position to suit the needs of the device. Such manipulation is invaluable when x-raying badly injured persons.

STATE WIDE X-RAY FILM PROBE IN NEW YORK

ACTING Governor Lehman has appointed a committee to investigate the use of x-ray films in New York State institutions, hospitals, laboratories and clinics. Matthias Nicoll, Jr., M.D., State Health Commissioner, has been named as Chairman of the Committee.

CAMPAIGNS

THE most important and far-reaching campaign ahead is the Summer Round-Up of the Children, a health activity of the National Congress of Parents and Teachers, 5517 Germantown Ave., Philadelphia, Pa. More than 2,500 parent-teacher associations in 44 states participated in the 1928 "round-up." The plan of work is simple and workable. The "physical inspection form" was compiled by representatives of the American Medical Association and the American Child Health Association. An opportunity to coöperate with and utilize local parent-teacher associations!

"SEEING THROUGH LIFE"

THE recently released annual report of the National Society for the Prevention of Blindness presents in review pictorially, diagrammatically, schematically in word pictures and with figures the accomplishments for the year 1928. For the information of its supporters and those concerned with prevention, enough of a comprehensive picture is given to whet the appetite of the reader and convince him of the worthwhile work accomplished. Three cents in postage to the National Society for the Prevention of Blindness at 370 Seventh Avenue, New York, N. Y., will bring anyone a copy of this report who wishes to study this attractive method of presentation.

HEALTH EDUCATION CONFERENCE

THE American Child Health Association conducted a Health Education Conference at Sayville, Long Island, N. Y., June 17–21, at which contributions were received from all of the school departments which belong in a comprehensive school health program: the Elementary School, Secondary School and Teacher Training Sections. Curriculum Building and Integration was the main topic of the whole conference and each section devoted two meetings to Materials and Activities, one to Health Service and one to Problems of Organization.

Dr. John Sundwall of the University of Michigan, Fellow, A. P. H. A., was Chairman of the General Sessions and Dr. W. F. Walker, Field Director of the Committee on Administrative Practice of the A. P. H. A., represented this Association.

NEW PUBLIC HEALTH AGENCIES

PRESIDENT Portes Gil has ordered the establishment of two new branches of the Mexican Department of Public Health: an office of sanitary exchange and a service of industrial hygiene and social prevision. The first of these departments will have charge of collecting foreign data on public health, publishing Mexican accomplishments in that field, insuring observance of obligations assumed by Mexico in international conventions concerning public health with reference to reports and notices, and keeping informed as to international congresses of health and hygiene while furnishing the necessary material and documents to Mexican delegates to such congresses. The second department has been created to watch over the sanitary conditions in places of work and the home conditions of the laborers.

PERSONALS

DR. WILLIAM H. WELCH, President of the Maryland State Board of Health, has resigned this position. He is the Director Emeritus of the Johns Hopkins School of Hygiene and Public Health, and the duties in connection with this position are enough to keep him occupied full time.

DR. THOMAS S. CULLEN, of Baltimore, was appointed by Governor Ritchie to succeed Dr. William H. Welch on the Maryland State Board of Health.

DR. W. W. FENTON has been appointed City Health Officer of San Bernardino, Calif., to succeed Dr. Ivan Lewis Finkelberg.

DR. ELMER H. BEST has been elected Health Commissioner of Freeport, Ill.

DR. GEORGE A. BARNETT has been appointed Health Officer of Riverside, Ill.

DR. JOSEPH G. BOSLEY has been reelected Health Officer of Madison County, Ky.

DR. HENRY ALBERT has been reappointed State Commissioner of Health of Iowa.

DR. THOMAS J. GLASSCOCK has been elected President of the North Dakota Health Officers Association.

DR. GEORGE D. HEATH, JR., has been appointed Health Commissioner of Florence, S. C., succeeding the late Dr. Percy H. Brigham.

DR. JAMES G. BLACK has been chosen Health Officer of Rutherford County, Tenn., succeeding Dr. Harry S. Mustard, resigned.

DR. W. F. WALKER, Field Director of the Committee on Administrative Practice, addressed the American Legion at Racine, Wis., June 6, on the Preschool Round-up. At the Annual Conference of Health Officers and Public Health Nurses at Saratoga Springs, N. Y., June 25–27, 1929, Dr. Walker gave an address on the Appraisal of Nursing Service.

CONFERENCES

July 8–12, American Medical Association, Portland, Ore.

July 9, American Heart Association, Portland, Ore.

Sept. 26–28, Association of Military Surgeons of the United States, Denver, Colo.

Sept. 30–Oct. 5, American Public Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, American Child Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, International Society of Medical Health Officers, Minneapolis, Minn.

Sept. 30–Oct. 5, American Association of School Physicians, Minneapolis, Minn.

Sept. 30–Oct. 5, Northwest Conference of Child Health and Parent Education, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Sanitary Conference, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Public Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Organization for Public Health Nursing, Minneapolis, Minn.

Sept. 30–Oct. 5, American Social Hygiene Association, Minneapolis, Minn.

Sept. 30–Oct. 5, Conference of State Laboratory Directors, Minneapolis, Minn.

Sept. 30–week, National Safety Council, Chicago, Ill.

FOREIGN

July 25–Aug. 4, World Federation of Education Associations, Geneva, Switzerland

Aug. 8–21, World Conference on New Education, Elsinore, Denmark

Aug. 22–29, Adult Education Conference, Cambridge, England

The Factor of Chance in Diphtheria Mortality

WALTER W. LEE, M. D.

Assistant Secretary, State Board of Health, Indianapolis, Ind.

THE present decade is the beginning of a new era in public health as far as diphtheria is concerned. Although the method of active immunization against diphtheria was discovered in 1912 it was not until 1922 that it was done on a scale of sufficient magnitude to influence the mortality rates. At that time the death rates from this disease were about 20 per 100,000 population. By 1925 the rate had steadily fallen to around 6. In 1927 throughout the United States and Canada the rates have tended to increase, averaging around 8. In the meantime 6 cities of over 100,000 population have reduced rates to close to zero and several smaller cities and counties have done likewise. There is scarcely a city or hamlet on this continent that has not used diphtheria immunization to some extent and yet the disease, after reaching its low level two years ago, is increasing.

Has diphtheria immunization failed to check diphtheria? Is the increase in the death rates real or apparent?

Immunization with either toxin-antitoxin or toxoid will prevent diphtheria in exact proportion to the extent of its use in the population under 10 years of age. This has been demonstrated in several cities of the United States and Canada. The greatest amount of immunization work has been done among school children, but very little has been done among the preschool population. In so far as the latter group has been neglected, the results have failed to lower significantly the general diphtheria mortality rates.

If we wish to estimate the significance of the present rise in the diphtheria death rate we must base our judgment on past experience.

The reliability of our final judgment must be proportional to the amount of reliable data on which it is based. Data for 10 or even 20 years are not enough for our purpose, especially when we have reliable data for 50 years available. Data for three communities are submitted here as samples of a large series, each one representing, in a general way, a different class.

The data have been plotted as the logarithms of the diphtheria death rates on plain cross-section paper. The slope of the trends has been determined by inspection. The positions of the trends have been adjusted so that the sum of the deviations of the rates from the trends in each instance is zero. The Standard Deviation (S. D.) is a measure of the annual fluctuation of the rates above and below the trend and is the square root of the average square of the deviations of the rates above and below the trend. Parallel lines are drawn above and below the trend line at distances of the S. D. and 2 S. D.

According to the laws of chance, frequencies in a series of chance events will distribute themselves about their mean or trend in such a manner that 66 per cent will fall within the range of the S. D. plus or minus, 95 per cent within the range of 2 S. D. with 5 per cent beyond. The 2 S. D. lines indicate the range, within which the rates may fluctuate from year to year, due to the influence of chance alone.

The accompanying graphs show that diphtheria death rates scatter about their trend in a manner similar to what would be expected were their distribution governed solely by chance. But other factors than chance operate in diphtheria. Contact between cases or carriers and susceptible individuals influences the prevalence of the disease. Natural active immunization of the population following an epidemic probably tends to cause the disease to progress in waves, with intervals of 10 years, more or less, between the peaks, as shown in Figure II. The trends in all three graphs are equal in slope, and in Figures I and III have continued in the same general slope for over 50 years. Note that the general average death rates represented by the trends are lower in New Haven than in Massachusetts, and those of Toronto are the highest. The average for each series as calculated from the trends for 1895 and 1928 are as follows:

	NEW HAVEN	MASSACHUSETTS	TORONTO
1895	39.0	50.0	77.5
1928	5.9	8.6	13.2

Diphtheria in New Haven has always been relatively low and in Toronto relatively high. Just what factor or factors have operated to cause this variation in death rates in the various communities, or the general depression of the death rates, is matter for speculation.

Diminished virulence of the causative agent, increased resistance of the population, increased use of antitoxin, quarantine and isolation of cases and carriers, with other factors, known and unknown, probably have had a part in the general reduction. After studying the course of this disease over a long period of years and in different situations, one cannot but be impressed by the predominance of the factor of chance in influencing the distribution of mortality.

Observe the data for Massachusetts—Antitoxin was introduced in 1895, and by 1898 the death rate dropped over 60 per cent. At that time there was reason to believe that the use of antitoxin had caused this change. The deviation is nearly 3 S. D. below the trend, and if only the data from 1875 to 1898 had been studied the deviation would have been still greater, probably 4 S. D. Such a drop might occur by chance, two or three times in 1,000 years. Had this experience been repeated in 1899 it would have been significant; but instead, the next year the rate was back at about its previous level. This transient drop was undoubtedly a chance phenomenon. A great part of the depression disappears if the data are calculated on the basis of the epidemiological year, September 1 to August 31, as indicated by the dotted curve in the graph. In 1926 the rate dropped again below the range of 2 S. D., returning to within this range in 1927. This drop is not significantly altered when the data are based on the epidemiological year. Such a drop beyond 2 S. D. is expected in a chance series about five times in 100 years, therefore, is not statistically significant. A certain amount of toxin-antitoxin has been used in the state in the last few years and may have had an influence in this drop; but whether or not this is true, the fall in the rate was insufficient to be considered significant, and may have been a purely chance occurrence. On the basis of the experience of Massachusetts since 1875, the expected average rate for 1928 is 8.6, with a possible deviation from that average to anything between 6 and 13, due entirely to chance, and neither extreme could be considered good or bad. The 1928 rate was again slightly below the 2 S. D. line and the rates for the next few years will show how significant is the reduction in the rates since 1925.

Figure IA shows the data for Massachusetts plotted on plain cross-section paper as numbers. This is the ordinary graph with which everyone is familiar. The lines representing the trend and S. D. and 2 S. D. are transposed from the logarithmic graph, converted into numbers and plotted arithmetically. Note that the space between the lines representing + S. D. and + 2 S. D. is wider than that between — S. D. and — 2 S. D. If we measure the spaces and compare them with the data their relative positions represent, we find that

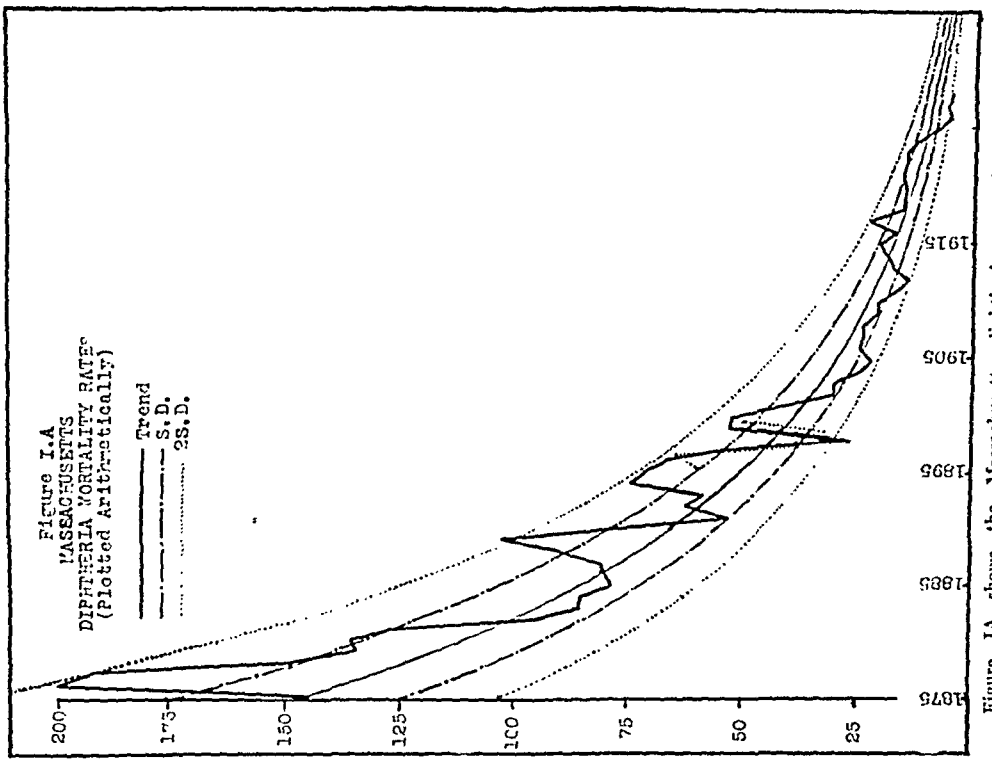

Figure IA shows the Massachusetts diphtheria mortality rates plotted arithmetically.

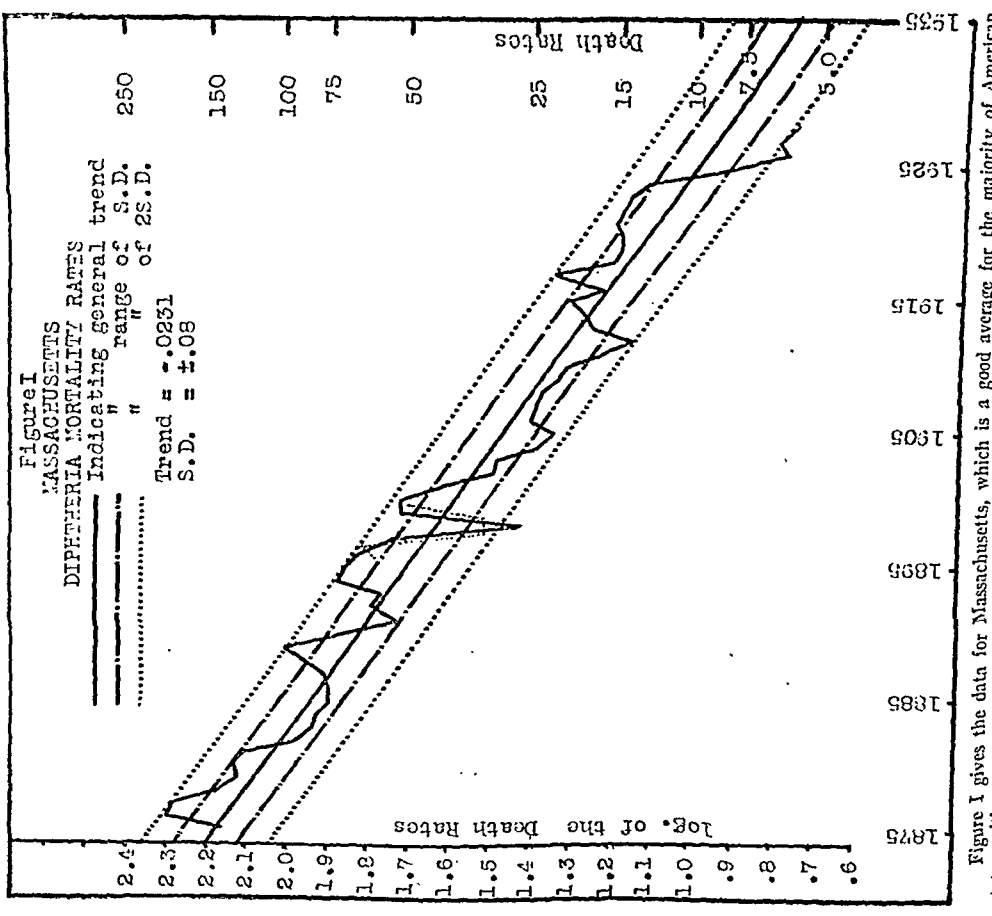

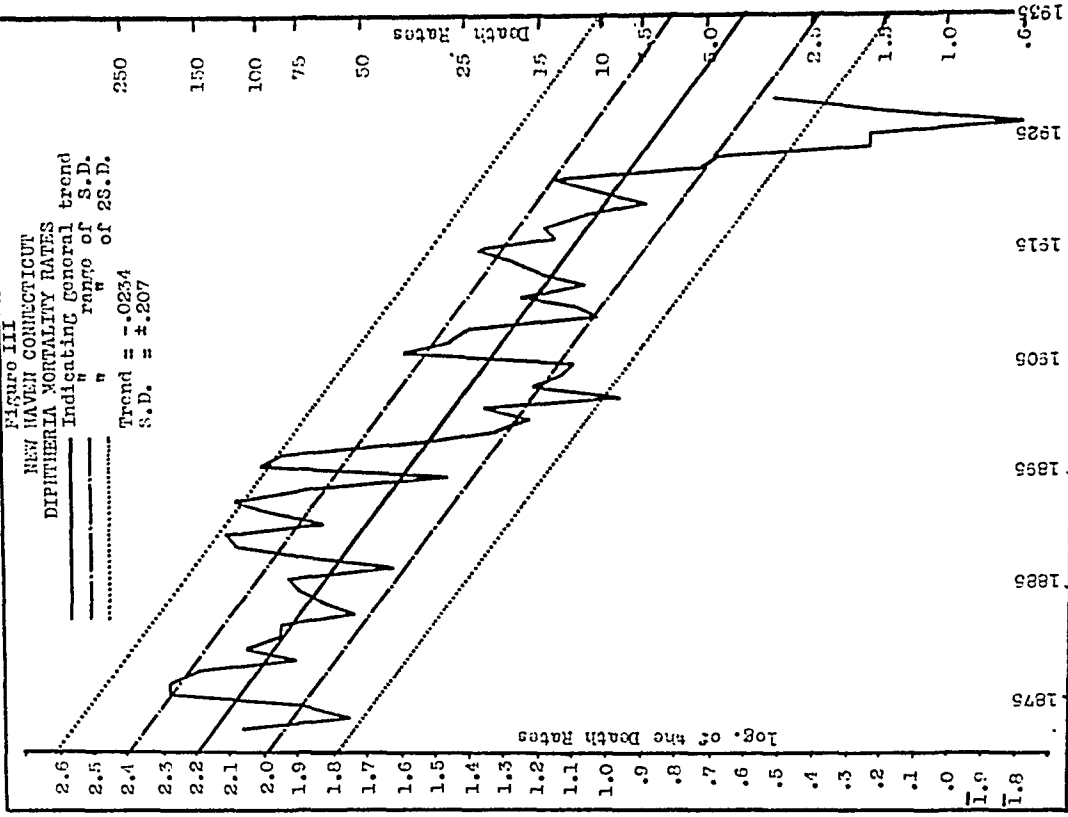

Figure I gives the data for Massachusetts, which is a good average for the majority of American states, with an average diphtheria mortality rate of about 8.5.

the ratios are equal. Note also that the lines representing the trend $\pm$ S. D. and $\pm$ 2 S. D. starting at 1935 and looking backward, diverge fanwise. This is due to the change in the magnitude of the data.

Note that in the arithmetic graph the data prior to 1900 are very unstable, while those since 1900 fluctuate only slightly. Compare this with the logarithmic graph and it will be seen that there the data fluctuate equally all the way. This difference in the fluctuations is apparent only, due to the change in the magnitude of the data. Although the actual fluctuations are greater, they all bear the same ratio to the general trend all the way along. Note also that practically all the data fall within the $\pm$ 2 S. D. lines as in the logarithmic graph.

Observe the Toronto data, Figure II. The population of Massachusetts is six times that of Toronto and the log. of the S. D. for Toronto data is exactly twice that for Massachusetts, due to the difference in population. If chance alone were operating, one could say that in 1928 the chances would be two to one that Toronto would have a diphtheria death rate between 20 and 9, and a chance of nearly one to two that it would be between 20 and 29, or between 9 and 6.3 with one chance in twenty of the rate exceeding either of the extremes. In 1928, the rate dropped to 8.2. It is impossible to estimate the influence of the immunization of 21,000 children in 1927 in this reduction. It was no doubt a factor, but greater reductions have occurred in the past without the aid of immunization and the reduction is well within the range of chance fluctuation. We must wait a few more years before we will see significant effects of immunization in Toronto.

Next consider the graph for New Haven, Conn. In calculating the S. D., the years 1924–1928 were not included, for these data have obviously been influenced by another factor not operating the previous years. The population is about one-third that of Toronto and consequently the S. D. is greater. In 50 years prior to 1924 the death rates deviated three times from the general trend by slightly more than 2 S. D., which is statistically insignificant. In 1924 the death rate dropped below the trend line a distance of 3 S. D., an event that might have occurred by pure chance about once in 500 years. In 1925 the rate was the same, and might have occurred likewise by chance once in 250,000 years. Then in 1926 the rate exceeded 5 S. D. and in 1927 nearly 3 S. D. again. It is therefore obvious that a new and potent factor was at work in New Haven beside that of chance. As a matter of fact, since 1923, New Haven has, among other public health activities, immunized about one-half its susceptible children against diphtheria and the result is exactly what one would expect. If in 1925 the death rate had been 2.7 or more, instead of 1.7, the drop of 1924 would have

In Figure III the data for New Haven, Conn., are given and are similar to those of Hamilton, Can., Auburn and Syracuse, N. Y., Cambridge, Mass., and St. Paul, Minn. This graph represents cities in which intensive diphtheria immunization has been done and in which the death rate has subsequently fallen.

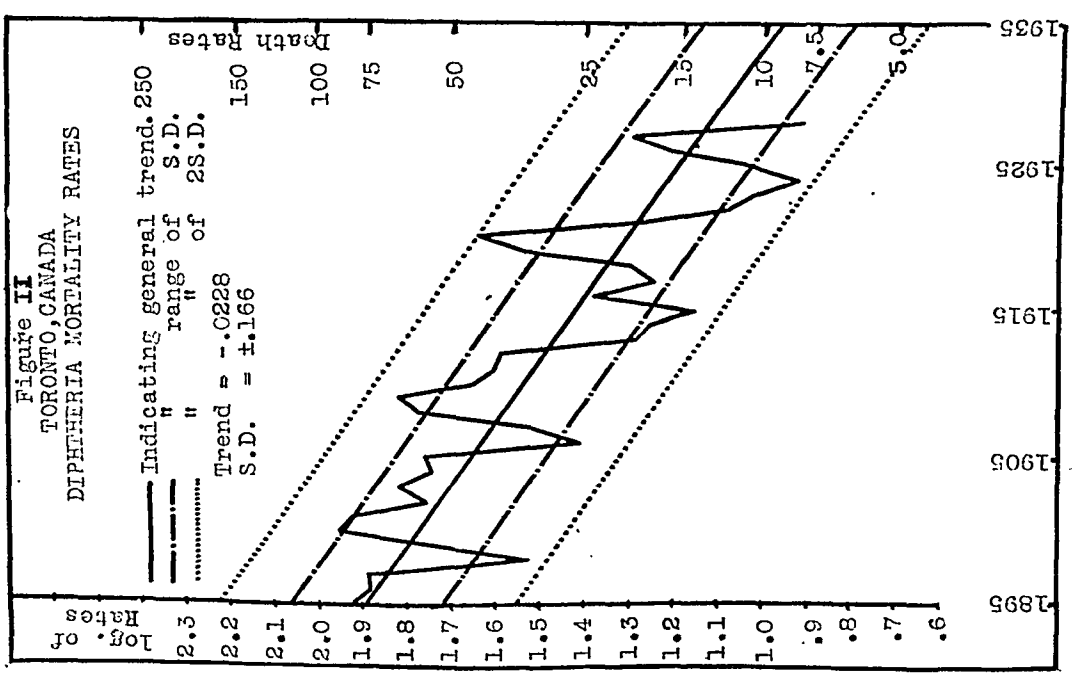

Figure II shows the data for Toronto, Can., which are similar to those of Detroit, Mich., Cleveland, O., and other cities, and represent a group with a relatively high diphtheria mortality rate of around 13.

been of doubtful significance, especially if, following 1925, the rate had continued between 2.7 and 6.3 as would have been expected had toxin-antitoxin not been used. As it is now, irrespective of what may happen in the future, the data show that some factor has operated to reduce New Haven's diphtheria death rate, and we have reason to believe that the factor is toxin-antitoxin immunization of one-half the child population.

Diphtheria mortality rates in Indiana, calculated on the basis of the epidemiological year, fell from 24.1 in 1921 to 5.4 in 1926, but in 1927 and 1928 the rates were 6.8. Indiana data go back to 1900 only, hardly sufficient time to draw definite conclusions, but what data we have, when compared with the older data of other states, show that the extremes of 1921 and 1926 are within the range of chance distribution. On the basis of 28 years' experience, the expected average for the coming year is about 7 with a range of fluctuation due to chance alone of anything between 4 and 13.

When chance is a factor of such great importance in the distribution of our death rates, it seems to be a waste of energy to worry over a fluctuation of one to five units in a death rate, provided always that the scattering of the rates, as measured by the S. D. of the data under consideration, is not of sufficient magnitude to disturb significantly the general trend of the series.

As far as the writer has observed, only 8 cities in Canada and the United States have to date immunized a sufficiently large proportion of their population under 10 years of age, so that their diphtheria death rates have dropped below 2 S. D. of their data. In cities under 100,000 population the data are so unstable due to the size of the population that, with the average expected death rate around 10, the S. D. is so large that a reduction of the death rate even to zero can hardly be statistically significant unless the favorable rates are repeated as they were in Auburn, N. Y., 1925–1927, when the rate remained at zero for the 3 years in succession.

In many of our great cities, immunization has been carried on for years in the schools, yet their diphtheria death rates continue on within the normal range of the general trend, due no doubt to the fact that a large percentage of the immunization work has been done among children of the older age groups.

Diphtheria immunization is an undertaking of great magnitude and wonderful possibilities, and requires intensive work concentrated on the 0–10 year age group. According to the experience of the cities where this has been done the death rate will not be lowered significantly, so that it will drop more than 2 S. D. below the general trend

for the city, until about one-half the child population has been immunized.

The S. D. is a yardstick which is invaluable to health officers as a means of measuring statistically the results of work done in a community. By means of such measurement, one can avoid the error of attributing to health activities events that are due to pure chance and good luck. It likewise affords us a measure whereby we may estimate the significance of the deviation of our death rates from the general trend, thereby apportioning to each datum its true value in relation to past experience and future probability.

SUMMARY

1. Beginning in 1922 diphtheria mortality rates have tended to fall, reaching a minimum in 1925–1926, since which time they have shown a tendency to increase from one to three units. This increase is entirely insignificant, and is what we would expect merely from the operation of pure chance, as is shown by the graphs for Massachusetts, Toronto and New Haven. These data show that rates may scatter from three to ten units above or below the average rate, depending on the size of the population involved, without significantly disturbing the general trend of the death rates.

2. Although a considerable amount of diphtheria immunization has been done in every city, there are only a few cases where enough has been done to lower the death rates significantly.

3. In cities where diphtheria deaths have been significantly lowered, it was accomplished only after about one-half of the susceptible population under 10 years of age had been immunized.

4. If we wish to judge the relative value of recent data or project our estimate into the future, the value of our judgment will be proportional to our knowledge of past experience. As an efficient aid in such calculations, the trend of the data is a stable and reliable landmark from which to work, and the Standard Deviation is a yardstick readily obtained.

Your Vacation.

THE sheltered life we lead during the greater part of the year is contrasted with the usual rough and tumble of the summer holiday in an attractive leaflet published by the Life Conservation Service of the John Hancock Mutual Life Insurance Company, Boston, Mass. The pitfalls awaiting the unwary tourist and camper are stressed, and suggestions for sensible summer behavior include advice about the selection of drinking water and milk supplies, exposure of the body to sun, overexercise and health examinations. This brief, pointed illustrated leaflet of 6 paragraphs will be supplied free to health agencies in quantities sufficient to meet their needs.

International Health*

FRANK G. BOUDREAU, M. D., C. M.

Health Section, League of Nations, Geneva, Switzerland

ORGANIZED international collaboration in hygiene is no longer a matter of experiment, but is, after some 7 years of trial, an accepted fact. It is perhaps not too much to say that the public health services of the various governments have come to realize the value of the facilities offered at Geneva for fruitful collaboration in the study and prevention of disease; and the use of these facilities has become in many cases a matter of routine. I should like to emphasize the need for such collaboration, and to attempt to show that the international health work of which I speak is only one of the activities of an organization created by a large majority of the countries of the world, and now maintained for the purpose of organizing their external relationships in the increasingly complicated world in which we live.

The need for international health work was felt long before any international health organization existed. About the middle of the 19th century the improvement in communication and transportation and the growth of industry and commerce, which had the effect of lessening the effective size of the world and of decreasing the economic independence of the various countries, created an unprecedented network of international relationships which obviously required organization if even a semblance of order were to obtain. Problems arose which required for solution the common action of a number of countries. When a problem became particularly acute a government took upon itself the responsibility of calling an international conference, and during the last half of the 19th century such conferences became more and more numerous. These pioneer attempts to solve problems arising in the international field were not always crowned with success, and the experience with the international sanitary conferences illustrates the difficulties and disappointments involved.

The first international sanitary conference was called by the French Government in 1851, in order to secure agreement in matters of maritime quarantine and to obtain united action in the prevention of cholera and plague. It was hoped that the issue of such a con-

---

* Presented at a General Session of the American Public Health Association, at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

ference would be a convention or agreement among the participating countries prepared by the conference, signed by the delegates, and later ratified by a sufficient number of governments to bring it into effect.

A number of such conventions or draft agreements were prepared by the 20 sanitary conferences held during the last half of the 19th century; but it was not until 1893, 42 years after the first one was held, that a sufficient number of governments ratified a sanitary convention to make of it an effective instrument of international intercourse. In considering the progress of international health work today difficulties such as these obtaining so recently must be borne in mind.

While international sanitary conferences were being held, the governments were attempting to solve problems in other fields by the same means. Thus, postal affairs came up for consideration by international conferences, and this important matter was solved by the creation of a Universal Postal Union in 1878. Those who may be interested in the organization of international relationships should read the brochure on this subject written by Prof. John F. Sly.[1]

The growth of commerce and industry forced other problems on the attention of governments, so that international conferences were called to deal with such problems as universal standards of weights and measures, the gauge of railroad tracks, customs declarations, telegraphic communication and others which new world conditions had made of interest to many instead of to only one or two countries.

Experience showed that if international conferences were to achieve their object of securing general agreement, they must be well prepared, the views of the various governments being ascertained and exchanged beforehand; they must be properly conducted with adequate provision for interpretation and secretarial work; and some neutral agency must make a business of following up the matter so that the convention or agreement secured would not become a dead letter.

These desiderata were obtained in the case of postal affairs and weights and measures by the creation of international organizations with permanent secretariats, which have been called little Leagues of Nations, established for the purpose of organizing international relationships in a particular field, and providing machinery for the continuous collaboration of the governments in respect of that problem.

International sanitary conferences which met at intervals of from 4 to 6 years after 1851 emphasized the need for a permanent international health organization; but it was not until 1907 that such an

organization was agreed upon at an international conference held in Rome.

CREATION OF OFFICE INTERNATIONAL D'HYGIENE PUBLIQUE

The organization, known as the Office international d'Hygiène publique (International Public Health Office) began to function, with headquarters in Paris, in 1908 and since then has had a continuous and useful existence.

It consists of a standing committee meeting twice a year at Paris, and a small permanent secretarial staff, including a director and the necessary clerical assistance. The committee is composed of representatives of the public health administrations of those governments which have ratified the Rome arrangement (some 45 at present) and as these representatives are briefed by their governments they sit on the committee as government representatives.

The Office international d'Hygiène publique was the agency entrusted with the application of the international sanitary convention, which was redrafted in 1912 at a conference held in Paris, and again redrafted in 1926 at another conference called for the purpose by the French Government.

In the meantime the World War had seriously interfered with all organized international intercourse, while creating a situation in which international problems had become more numerous and acute. It was in these conditions that the Health Organization of the League of Nations was created.

PLAN OF THE HEALTH ORGANIZATION OF THE LEAGUE OF NATIONS

It is needless to describe the steps leading to the establishment of the present Health Organization. Nevertheless, I must insist on the importance of certain features of that organization in order to show the difference between present and pre-war conditions, and to permit you to judge how well the present facilities for international collaboration in hygiene measure up to the existing needs and opportunities.

The present Health Organization of the League consists of three parts:

Advisory Council
Health Committee
Permanent Secretariat

Advisory Council—The Advisory Council is constituted by the Standing Committee of the Office international d'Hygiène publique, previously referred to. This committee, composed as it is of delegates from the public health services of some 45 governments, is well fitted

to act as an advisory council and to speak for the health administrations of the world on any policy or activity relating to international health. It receives all reports of the Health Committee, which may refer to it any matter in which its advice or opinion may be desirable. While this committee thus serves as an advisory body for the Health Organization of the League of Nations, the fact that it is a separate and independent international organization must not be forgotten.

Health Committee—The Health Committee of the League is a body of experts in hygiene set up to advise the Assembly and Council of the League on matters relating to international health. There are 24 members (3 from the United States). This committee meets twice a year, usually at Geneva, and all its resolutions must be approved by the Council of the League before they are acted upon.

There are two fundamental differences between the Health Committee of the League and the Standing Committee of the Office international d'Hygiène publique:

1. The members of the Health Committee do not sit on that committee as delegates of their governments. They are simply selected as health experts in their capacity as individuals, which explains the presence of members from countries which have not adhered to the Covenant of the League of Nations.
2. The Health Committee is a part of a much larger international organization, and its work is bound up with that of other organs of the League.

Permanent Secretariat—The Health Section is a part of the General Secretariat of the League of Nations, a body of permanent officials which has been likened to an international civil service. It consists of some 15 physicians of various nationalities and the necessary clerical assistance. The majority of the Health Section is to be found at Geneva, the seat of the League of Nations, but it has another important seat at Singapore.

RELATIONS OF HEALTH ORGANIZATION WITH OTHER LEAGUE ORGANS

The League of Nations itself consists of an Assembly, a Council, and a General Secretariat. The Assembly is made up of 3 delegates from each State Member, and these meet regularly in Geneva every September for a period of from 3 to 4 weeks. Press accounts of the Assembly emphasize the plenary sessions and the general debate, frequently on political questions, but the work of the committees into which it is divided is not frequently mentioned; yet these 6 committees carry on some of the most important work that is done in Geneva. Two of these committees are concerned with the work of the Health Organization—the Second and Fourth.

The Second Committee of the Assembly reviews the work of the

technical organizations of the League, of which there are three, Health, Financial and Economic, Communications and Transit. Reports on the work of the Health Organization during the past 12 months are received by the Second Committee; there is a general debate on the subject, and a rapporteur is appointed who prepares a report for submission to the Assembly summarizing the debate and ending in a resolution of approval. During the debate there may be criticism, approbation, and proposals for new work. During the last session of the Assembly, for instance, delegates from Australia, Japan, Spain, Poland, India, Italy and Holland spoke in warm terms of the value of the Health Organization's work, and Mr. O'Sullivan, Minister of Public Instruction in the Government of the Irish Free State, prepared a report which was presented to a plenary session of the Assembly and approved. You will therefore appreciate that the Health Organization of the League possesses an important relationship with the Assembly itself, so that international health problems are discussed not only in Assembly Committees but also in plenary sessions.

The Fourth Committee of the Assembly considers the budget of the Health Organization. This year the budget for 1929 was approved as presented to that committee.

The Council of the League, which usually meets four times yearly, and consists of 9 temporary and 5 permanent members, must approve resolutions adopted by the Health Committee before they become effective. One of the members of the Council is appointed rapporteur on health, and it becomes his duty to prepare a report for the Council's consideration. For several years the distinguished delegate from Japan has acted in this capacity. This year the rapporteur on health is the delegate from Spain. The Council may refer any health problem to the Health Committee for advice and this has been done not infrequently in the past. The Assembly also frequently refers international health questions raised by the delegates to the Health Organization for advice or investigation.

The General Secretariat of the League, referred to above, is under the direction of a Secretary-General. It is divided into Sections, each with some particular preoccupation, such as health, finance, economics, disarmament, etc. As the Health Section is an integral part of the General Secretariat it is natural to presume that the relation of health questions to other international problems will be given due recognition.

The Health Organization has important relations with other organizations of the League. For instance, it is jointly concerned with the Financial and Economic Organization, in the settlement of Greek and Bulgarian refugees. The Greek Refugee Settlement Commission

and the similar Commission set up by the League to deal with the problem of Bulgarian refugees found that questions of health must be settled before progress could be made. In both cases malaria was prevalent and in addition tuberculosis was rife among the refugees in Greece. On the recommendation of the respective commissions, the Health Organization was consulted and is now collaborating actively with the public health services of both these countries in dealing with these problems.

The Health Organization of the League, like the League itself, is not so much an entity apart from the governments which form it as a method of facilitating the collaboration of those governments in the international field. Thus the very constitution of the Health Organization permits it to draw upon the most expert services available in the world to deal with any problem. Experts in the prevention of tuberculosis from various countries would gladly accept the invitation of the Health Organization to advise it in regard to the campaign in Greece, for instance, and the latter would have no hesitancy in calling for assistance from an organization in which she is a full partner.

The Health Organization has relations with that Section of the League dealing with Opium as well as Social and Humanitarian questions. It was called upon to define the maximum legitimate consumption of opium and cocaine for the International Conferences which drafted the opium convention now in effect.

The Mandates Commission, which reviews the annual reports of mandatory powers on their administration of mandated territories, refers to the Health Committee the chapters of these reports dealing with hygiene and public health.

The Organization for Communications and Transit is in frequent relationship with the Health Organization, as health questions and maritime quarantine seriously influence maritime traffic, and joint commissions have been set up by these two League organizations to deal with problems in which both are interested.

These are only a few of many examples which could be mentioned to show that the Health Organization derives much benefit from its position in a complete international organization, and, of course, the advantages are not altogether one-sided.

RELATIONS WITH THE "WINGS" OF THE LEAGUE

Two organizations, sometimes called wings of the League, to indicate that they have an independent existence, are the International Labour Office at Geneva and the Permanent Court of International Justice at the Hague.

The International Labour Office is an organization somewhat resembling the League itself, with an annual International Labour Conference instead of an Assembly, a Governing Body in place of the Council, and a General Secretariat in all respects similar to that of the League. It deals with questions affecting labour, and is therefore concerned with industrial hygiene. Necessarily certain aspects of industrial hygiene also interest the Health Organization of the League, and joint commissions representing the two organizations meet not infrequently to deal with such problems to the best advantage. Two such joint commissions are at present studying the preventive aspects of health insurance with a view to the improvement of the services and conservation of the resources available for the purposes of preventive medicine.

No question affecting the Health Organization of the League has so far come up before the Permanent Court of International Justice, but in case the Council of the League wished to ascertain whether the Health Organization was competent to deal with a particular problem, the Court might be asked for an opinion.

There is therefore a vast difference in the adequacy of the machinery for international collaboration available now and the more primitive forms elaborated in the pre-war period. At present machinery exists capable of dealing with almost any question affecting international relations, while before the little Leagues of Nations previously referred to were constituted, each to deal with one particular subject, no machinery existed for dealing with many others.

The Health Organization of the League as an organization is very young. Its possibilities have hardly been explored. In considering it we must not think of the small secretariat at Geneva, but rather of the great resources of the health administrations of the world, for the secretariat at Geneva exists simply as a means of facilitating the collaboration of those administrations.

WORK OF THE HEALTH ORGANIZATION

Of the developments the most important has been the establishment and organization of the Eastern Bureau at Singapore. I should like to call your attention to the fact that, alone among the organs of the League, the Health Organization possesses two technical bureaus, the one at Geneva and the other at Singapore.

Singapore has been well called the crossroads of epidemic disease, and here, the Health Administrations of the Far East recommended, would be the best place to establish a bureau of the League's Health Organization. Approval by the Health Committee and the Council

of the League was forthcoming promptly, and in March, 1925, the bureau began to function. The need for such a bureau had been demonstrated many years before, but in the international field something more than the demonstration of a need is required to provoke action. Before the League existed it required many weary years to secure international agreement in regard to such matters as quarantine, but when the bureau at Singapore was founded the League had already served its apprenticeship as a means of promoting and facilitating international action. In the case of this bureau, action followed recommendation as rapidly as could be expected.

The Japanese member of the Health Committee had in 1922 called the attention of the Committee to the epidemic situation in the Far East, and had recommended the dispatch of a mission to discover the amount and importance of the information available concerning the prevalence and control of epidemic diseases in the ports of the Far East. On the completion of the survey, a conference of the Far Eastern Health Administrations was convened, and as soon as it was ascertained that these administrations favored and would support such a bureau, the steps necessary for its establishment were taken, and the bureau began to function on March 1, 1925, receiving and transmitting information in regard to the important epidemic diseases in the ports of the Far East. During the first week this information related to 35 ports controlled by 12 administrations. Exactly 3 years later, the bureau was in weekly touch with nearly 140 ports, and now even this figure has been exceeded, while the scope of the information itself has been much increased.

The diseases concerned are cholera, plague, rat plague, smallpox, yellow fever, dysentery and any other prevalent or epidemic disease. The information is sent by cable to Singapore, immediately if it relates to a new outbreak, weekly if it has been prevailing.

All these cables pouring in from the Health Administrations which control the whole of the area bounded by the East Coast of Africa, Australia, New Zealand and the Pacific Islands, India, Japan, China and certain ports of Russia, are made into a coded message and broadcast by wireless on Thursday, Friday and Saturday of each week from 9 powerful broadcasting stations placed at the disposal of the Eastern Bureau by the governments to whom they belong. The message is still sent by cable to a few administrations which have not yet succeeded in picking up the wireless broadcasts regularly.

For the benefit of ships at sea, a number of less powerful broadcasting stations transmit the messages in clear so that the officers of

any ship equipped with wireless in Eastern waters may learn all that is known to the Health Administrations concerning the disease conditions in the ports at which she may touch. Information in regard to the movement of infected ships is also collected and distributed, and in 1927 the bureau notified the arrival of 165 ships infected with such diseases as smallpox, cholera, influenza, cerebrospinal meningitis, plague, and typhus.

The wireless message broadcast weekly by the bureau is supplemented by a weekly bulletin confirming the message and containing additional information of interest. The Health Administrations concerned send representatives to a yearly conference, known as the Advisory Council, in order to advise the Health Committee of the League on the conduct of the bureau. On the advice of the Advisory Council the work of the bureau has been extended beyond the limits first proposed. By means of its facilities the Health Administrations of the Far East are carrying on coördinated studies of plague, cholera, port quarantine, and the seasonal prevalence of epidemics.

While the Eastern Bureau of the League's Health Organization is a physical entity, it is also, like the League itself, a method of work, a means of giving effect to the desires of the Health Administrations concerned, for profitable international coöperation, an instrument for organizing and facilitating international relationships.

As you know, the Health Organization at Geneva collects and publishes epidemiological information from the world as a whole. Daily, weekly and monthly bulletins are distributed containing all the information received from the various countries. All the information received at Geneva, all the cables sent to Singapore, are the voluntary offerings of the Health Administrations concerned—no Health Administration is obliged by any international law or agreement to go to the trouble and expense of collecting and transmitting this information to Singapore or Geneva.

This will serve to emphasize the fact that the League has provided in the field of international health a means of giving practical expression to the desire, nay, to the need, of the various governments for collaboration in the prevention of disease.

INTERCHANGES OR STUDY TOURS OF PUBLIC HEALTH PERSONNEL

When the Health Organization of the League was first founded, its task was to promote the collaboration of the various governments which had pledged themselves by the terms of paragraph (f), Article 23, of the Covenant to " take steps in matters of international concern for the prevention and control of disease."

The international situation at that time was far from being as satisfactory as it is at present. Governments of countries lately at war were not readily disposed to collaborate. Yet there was great need for common action against epidemic diseases which were spreading from East to West and threatening to overwhelm the whole of Europe. Among the various methods of promoting international collaboration employed by the Health Organization of the League was the system of interchanges or study tours which has now become a permanent and fruitful activity. To clarify the subject let me describe an interchange which took place during the summer of 1928.

In view of the importance of rural hygiene it was decided to study this subject in several Eastern and Western European countries. Districts in each of these countries were visited by a member of the Health Section, and a detailed program of study prepared in collaboration with the Health Authorities concerned. The program included a review of the activities of every organization or agency having any influence on the health of the rural population.

An attempt was made to emphasize those features which were of particular interest in each country. For instance, practical public health education has attained a high development in the Kingdom of the Serbs, Croats and Slovenes; new and interesting schemes for sewage disposal in villages may be found in Hungary; health insurance has reached a high stage of development in Germany; in Holland, single water supplies for a number of villages have proved of great economic and hygienic value; the coöperative movement known as the Farmers' League in Belgium has not only raised the economic level of rural life, but is a potent force in public health education; while in some parts of rural France the health authorities have, by exceptional intelligence and ingenuity, applied a modern health program at a surprisingly low cost. These, it must be noted, are only a few of the many features of interest presented by each country.

After selecting the districts to be visited, competent health officers were requested to prepare booklets setting forth the main characteristics of rural hygiene, such as the organization, budgets, chief problems and activities of agencies other than the health organization which influence rural hygiene—in a word, descriptions intended to give to the visiting health officers as clear a picture as possible of all that makes up rural hygiene.

Sixteen public health officers and 7 sanitary engineers from 17 countries were invited to participate, and the booklets referred to were distributed in advance, so that each participant was in a position to profit from the tour. I had the pleasure of accompanying this

interchange from the beginning at Ljubljana on May 28, to the final conference held at Geneva on July 23, 24 and 25, 1928.

I am emphatically of the opinion that these interchanges furnish unique opportunities for the study of public health activity. No public health officer travelling alone for the same period can see anything like so complete a picture of public health organization and administration as is shown to the interchange group. Moreover, in the interchange on rural hygiene almost every phase of rural life was shown, so that the subject could be studied in its relation to the life and habits of the people. The great advantage of being able to examine at close range the varying activities of rural health departments in a number of countries differing sometimes widely in race, development, economic conditions and method of government, is too obvious to need emphasis. Also, the discussions which go on within the group are enlightening, for here the activities under consideration are seen from as many points of view as there are participants.

At the final conference in Geneva, nearly every participant stated that he had found something worthy of emulation in every one of the countries visited, and changes of importance in the health practice of a number of rural health departments will undoubtedly result. Health departments of countries in which interchanges have taken place have emphasized the benefit they themselves reap, partly as a result of the process of stock-taking necessary to present a clear description to the visitors, and partly as a result of the suggestions offered by the participants in the course of the informal and friendly discussions.

Since the system of interchanges was started in 1923, approximately 500 public health officers (including a few sanitary engineers and medical specialists) from 50 countries have participated, and approximately 40 countries have been visited. What have been the benefits?

I think no one would deny that these interchanges have fostered a splendid *esprit de corps* among the health services of the different countries. Perhaps this is the greatest benefit of all, and I am convinced that the cordial relationships established between health officials of different nationalities is of itself well worth the time and money spent for the purpose. But there are other and more practical advantages. There is the more general diffusion of knowledge concerning modern public health methods; there is more uniformity in public health practice, for the better methods are bound to be copied; and there is the accumulation of a common fund of knowledge as a result of friendly international comparison of experience and results. The

interchange is a powerful means of bringing about the reform of public health administration, and its results along this line have fully justified the expense involved.

POSTGRADUATE INSTRUCTION

Every public health officer needs to be reminded occasionally of the advances being made in the practice of preventive medicine. Postgraduate instruction in hygiene and public health is not sufficiently generalized to meet this need. And perhaps the system of interchanges fills this need more effectively than certain forms of postgraduate instruction, for in the interchange the participating health officer is enabled to witness the application of new public health methods in actual practice, where the results are most readily appreciated.

Variations of the interchange idea are the international courses in hygiene recently held in Paris and London and the malaria courses organized in London, Paris, Hamburg and Rome. These so-called continuation or "refresher" courses, organized by the Health Organization of the League in collaboration with the University of Paris and the British Ministry of Health, were an attempt to provide instruction to health officers on recent advances in the sciences underlying the practice of preventive medicine. The lecturers were selected from a number of countries, and were the individuals responsible for recent advances in our knowledge of such subjects as physiology, biometry, epidemiology, bacteriology, public health administration and sanitary engineering. The students were public health officers nominated by their administrations, and so popular were these courses that, at Paris, for example, nearly half of the group attended at their own expense or at the expense of the public health services to which they belonged.

The malaria courses are being organized for the fourth successive year. They are intended to afford, to public health officials charged with the campaign against malaria, theoretical and practical instruction in malaria control. The theoretical courses, lasting one month, are held at the institutes or schools of tropical hygiene in the several cities mentioned (at Rome in a school specially organized to teach malaria). The practical instruction, lasting 2 or 3 months, is given in Italy, Spain and Jugoslavia, where the student is enabled to assist in the campaign against malaria under the direction of experienced malariologists. These schools have enabled various governments to train staffs of malariologists in a short period of time, in order to deal with a pressing problem for which trained personnel had not been available.

Thus, by means of an international organization, the training facilities possessed by certain countries are being utilized by others not possessing these advantages.

It is hardly necessary to insist at greater length on the value of the system of interchanges. The Health Organization was enabled to organize this system through the generosity of the Rockefeller Foundation, which has continued its support for a number of years. The League itself makes a generous grant for this purpose, and successive Assemblies have insisted on the value and need for the extension of this activity.

STANDARDIZATION WORK

The need for common standards was early recognized by the American Public Health Association, which has achieved notable success in securing the adoption and extending the use of standard methods of water, milk and sewage analysis. Standard methods enable ready comparison, and uniform methods of recording results also facilitate international comparability. The setting up of international standards in respect to serums, biological preparations and serological reactions, has been a preoccupation of the Health Organization from the beginning, and although Dr. Madsen, the Chairman of the Health Committee, explained this work in detail at the Detroit session,* I must describe to you briefly the advances made since that time.

As a result of conferences convened by the Health Organization and of laboratory studies undertaken on its behalf by the leading public health laboratories of the world, agreement in regard to the units of a number of therapeutic serums such as diphtheria and tetanus antitoxins has been reached. This work was amplified during the past four years and now extends to anatoxin, anti-dysentery serum, scarlet fever toxin and serum, anti-gas-gangrene serums, tuberculin, standard serums for blood groups and the nomenclature of such blood groups. (I do not wish to imply that international units have been adopted for all these, but they are all being studied with that end in view.)

Furthermore a number of therapeutic substances requiring biological methods of testing have been studied with the object of international standardization. This group includes such substances as the salvarsans, digitalis, strophanthus, scilla, insulin, pituitary extract, thyroid preparations, ergot, filix mas and oil of chenopodium. This work requires considerable time, for stable preparations for reference purposes must be prepared. The responsibility for this work is usu-

* Madsen, Thorvald. Health Work of the League of Nations. Fifty-fourth Annual Meeting, American Public Health Association, Detroit, Mich., October 20, 1924.

ally entrusted to those individuals or laboratories which have had the greatest experience with the preparations in question.

Once a stable preparation is secured, the international unit adopted is expressed in terms of that preparation, and individual methods of testing are not as a rule interfered with. Samples of any of these preparations may be sent to the central laboratory for comparison with the stable preparation, and this work is done by a central laboratory selected on behalf of the Health Organization of the League, or samples of the stable preparation may be sent to the national laboratories desirous of making such comparisons. The Health Organization has no laboratory—all this work is done on its behalf by the various national laboratories, which again emphasizes the rôle of the Health Organization as a method of facilitating the collaboration of the different public health services.

The units adopted by the Permanent Standards Committee as a rule receive international recognition because they have been arrived at as a result of coördinated studies in the national institutes chiefly concerned, and no decision is made until agreement has been reached by the chiefs of the participating laboratories.

To members of the American Public Health Association it is hardly necessary to stress the desirability of such standardization work. It promotes better understanding among public health officials, the medical profession and laboratory workers; enables the value of improvements in methods of treatment to be appreciated more generally; and is a safeguard for countries where such preparations are not manufactured but must be imported from various sources. May it not be considered in the light of a common language, enabling technicians working with these preparations to understand more easily the communications of those having similar responsibilities in other countries?

INTERNATIONAL COMMISSION ON SLEEPING SICKNESS

During the last few years an interesting study of the etiology, epidemiology and prevention of sleeping sickness has been going on in Africa under the auspices of the Health Organization. A group of experts from the health services of England, Belgium, France, Germany, Portugal and Italy carried on for a period of 18 months a series of important field and laboratory investigations of this disease. The program was framed by an international conference of sleeping sickness experts convened by the Health Organization in London.

The Commission on Sleeping Sickness had headquarters at Entebbe on Lake Victoria in Uganda, and from this point its researches extended far into the field. The Commission was able to produce an

important volume on the epidemiology and prevention of sleeping sickness, and agreed on a number of administrative recommendations. This report and the recommendations are now being considered in Paris by an international conference of medical and administrative officers from the countries chiefly concerned.

I am sure you will agree that the steps taken to prepare and dispatch this commission to Africa, as well as to act on its recommendations, were logical and well advised. Working together as the members did in Africa, duplication of effort which might have resulted from separate investigations was avoided, and they had the great advantages of daily contact, exchange of ideas, and appreciation of results. I must add that the expense of the commission was borne by the participating governments—with a small grant from the Health Organization of the League.

INQUIRIES INTO INFANT MORTALITY

There are inquiries into the causes of infant mortality being carried on under the auspices of the Health Organization in selected urban and rural districts of England, Austria, France, Holland, Germany, Italy and Norway in Europe, and the Argentine, Brazil, Chile and Uruguay in South America. Several delegations to the Assembly of the League of Nations had asked the Health Organization to arrange an international study of the causes of infant mortality. The Health Committee of the League asked the advice of a number of child health experts, including Dame Janet Campbell of the British Ministry of Health, Pirquet of Vienna, Debré of Paris, Gini of Rome, Collett of Oslo, Gorter of Leyden, and Clark of the U. S. Public Health Service. These experts advised a study of infant deaths in selected districts of the countries listed above. This study applies to infants dying during the period of the inquiry, so that before and during the last illness every resource of science may be utilized in seeking the causes.

Interesting results have already been secured; for instance, there is a marked contrast between the causes of death as registered for official purposes and the real causes as elicited by the inquiry. The marked influence of prematurity on the infant death rate has been noted in all the European countries. Frequent meetings of the experts in charge of the inquiries guarantee that the studies will be carried out along similar lines and that the varying experience of the different countries will be comparable. A considerable amount of interest in the prevention of infant mortality has been aroused by this international consultation, which should lead to the better conservation of child life—perhaps by arousing healthy national rivalries. A

volume describing the results of the European inquiry will be issued in 1929.

HEALTH INSURANCE AND PREVENTIVE MEDICINE

A conference on Health Insurance was held last year in Geneva. To an American audience I presume this requires explanation, for health insurance on a governmental basis does not exist in the United States, and there has been serious opposition to the suggestion that it should be introduced. But in Europe health insurance is a fact, and its operation and results must be taken into account. As a rule health insurance is carried on under governmental supervision by more or less self-governing insurance organizations organized on a local or territorial basis. These organizations have been led by their unfortunate experience with such diseases as rheumatism and tuberculosis to attempt the application of preventive measures for the benefit of their members.

As the medical benefits accruing to the worker are usually also extended to the dependent members of his family, these organizations have been led to take measures for the protection of children and mothers. In view of the large populations involved (15,000,000 in England, nearly 40,000,000 in Germany, for example), and the comparatively large resources available, the efforts of health insurance organizations along preventive lines have quite naturally led to some duplication of services provided by governmental health agencies.

The Government of Czechoslovakia requested the Health Organization to take up the study of this question with a view to the more economical and effective prevention of disease. A conference on this subject was held last year in Geneva, under the chairmanship of Sir George Newman, Chief Medical Officer of the British Ministry of Health. There were present 6 representatives of public health services, nominated by the Health Organization of the League, and 6 representatives of health insurance organizations, nominated by the International Labour Office.

The Conference decided that the most practical way to proceed was to study the interplay of preventive effort in selected urban and rural districts of countries where different forms of health insurance were in force, in order to secure exact information on which to base recommendations for improvement and better coördination of effort. For instance, a sub-committee was set up to study tuberculosis prevention, another to report on the protection of mothers and infants, a third to deal with the measures applied to conserve the health of the child of school age, and so on.

These studies have been made, and the general committee will soon meet to discuss the results. I do not imagine that any dramatic reform will result immediately, for in this field change comes slowly. But here again is an example of a complex social problem of interest to a large number of governments being studied collectively instead of separately, with all the advantages inherent in this method, and the coördinating mechanism is again the Health Organization of the League of Nations.

The limits of space forbid me to go into further detail concerning the work of the Health Organization, although I have only touched superficially on a few of its activities. I have said nothing of the Malaria Commission which has been invited by the Indian Government to study the subject in India, and no reference has been made to leprosy, ship fumigation, rabies, smallpox and vaccination, cancer, vital statistics and syphilis, all of which are being studied in the international field by the Health Organization. These and other activities are described in the annual reports and other publications of the Health Organization which may be secured from the World Peace Foundation, 40 Mount Vernon Street, Boston, Mass.

As I have insisted throughout on the rôle of the Health Organization as a method of collaboration, I must not close without paying special tribute to Surgeon General Cumming, who has given us frequent evidences of his friendship, and has on many occasions extended to the Health Organization, and through it to the public health services of other countries, the collaboration and support of the U. S. Public Health Service.

The organization of international relationships in the complicated world in which we live may leave much to be desired; but may we not say that very considerable progress has been made?

Life is a Relay-race

LIFE is a great relay-race, and we cannot clearly see the goal. Each just runs his short lap and then hands on the torch. To one who nears the end of his lap it is a relief to know that young and strong runners are in sight. In these times science gives her prizes to the discoverer and treats the expositor with indifference; she smiles on the man who grows the corn, but overlooks him who bakes and distributes the bread. Yet for the welfare of knowledge both kinds of men are needed.—Foreword to *Good Health*—By Ian S. Thomson, 1929.

Coördination of Research on Sewage and Industrial Waste Disposal*

CLARENCE M. BAKER, M. C. E., FELLOW A. P. H. A.

Engineer, American Paper & Pulp Association, New York, N. Y.

PUBLIC health engineers are entering a new phase of stream pollution activities. Originally their efforts were directed almost exclusively against pollution affecting the public health. Later jurisdiction was extended to include welfare or comfort in order to include definitely those indeterminate conditions commonly designated as nuisances and which affect public health only indirectly, if at all. Recently public demand has necessitated consideration of pollution affecting fish and other aquatic life, that streams may be conserved in a reasonable state of purity for recreational and similar purposes.

The importance of domestic sewage in the transmission of communicable disease has justly focused the attention of health officials on this phase of the problem, notwithstanding the fact that in many cases the demand of industrial waste upon the oxygen resources of the stream is many times greater. Health officials have been loath to direct their efforts to pollution affecting fish life but are now finding it necessary to do so because of public demand, or else permit the establishment of such activities in other state departments which results in duplication of effort, misunderstandings and conflicting jurisdiction.

ANALYTICAL METHODS

The starting point with any problem of industrial waste disposal or stream pollution is analytical. Uniform analytical technic must be developed in order that the effect of the wastes upon the streams may be measured, and methods of disposal or treatment evaluated and reported in comparable figures. *Standard Methods of Water Analysis* was originally developed for the control of potable waters, but later extended to cover in a reasonably satisfactory manner the analyses of sewage and sewage effluents. Recently feeble attempts have been made to adapt these methods to the analyses of industrial wastes, but because of their greater concentration and composition

* Read at a Joint Session of the Public Health Engineering and Laboratory Sections of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 19, 1928.

such a procedure is impractical without material modifications made according to the individual views of the chemist in charge of the particular work, which has resulted in great discrepancies in the technic used in different laboratories.

Probably the greatest difficulty or discrepancy in the application of *Standard Methods* to the analyses of industrial wastes is in the very essential biochemical oxygen demand test. Here little variations in technic frequently make considerable differences in the results. In one state tap water was originally used for dilution, but comparable results could not be secured in different sections of the state, so distilled water, to which 500 p.p.m. sodium bicarbonate has been added, is now used. Another state is using distilled water without the bicarbonate, and in others tap water is still being used. Investigations have indicated that the use of distilled water produces results about 35 per cent lower than tap or synthesized water. With such variations in technic, comparable and consistent results cannot be secured.

With the development of coöperative programs in waste disposal between industry and health officials, industrial chemists find it necessary to apply sanitary analyses to a study of their local conditions. In referring to *Standard Methods* they find essential explanatory data lacking regarding basic principles and the significance of the analytical procedure. A like situation exists with a student or other individual who is just taking up the question. In order to apply the analytical procedure successfully and uniformly there must be a rather definite understanding of the basic principles and significance of analyses. It seems, therefore, that *Standard Methods* should include more definite, descriptive basic data. In other words, the publication should be written more in the form of a text than at present.

WASTE UTILIZATION AND TREATMENT

Industrial waste disposal may be divided into three definite steps:

1. Utilization of the wastes within the industry, which is primarily a problem for industry itself, and should be given first consideration.
2. Treatment of the residual wastes after as complete utilization as practical, which is more specifically a problem for sanitary engineers and state officials in coöperation with industry.
3. Stream surveys to determine the effect of the wastes upon the stream, the extent of waste treatment necessary, and the results of improvement made, which is primarily a function of the state.

While utilization of the waste within the industry is essentially industry's problem, the sanitary engineer must keep in close contact with developments to correlate them with the second and third stages

of the problem. Some contend that treatment of the waste is wholly a problem for industry, but there is now a tendency toward assisting industry, through state departments, in solving this difficult problem. Certainly the sanitary engineer is in better position to suggest methods of treatment and direct coöperative activities because of his intimate knowledge of such processes, based upon his experience with domestic sewage. It is the writer's belief that while the major cost of developing treatment processes for industrial wastes should be borne by industry, the state should be in a position to lead, and in some cases direct, experimental work.

Industry's first and principal consideration—waste utilization—involves not only the question of stream pollution, but also economical considerations. Outstanding examples in this respect include:

1. Reduction of the population equivalent of wastes from the Corn Products Plant at Argo, Ill., from 370,000 to 50,000 by waste utilization, resulting in a saving of $3,000,000 for a treatment plant and a financial return of probably $500,000 annually in the value of recovered products.
2. The installation of $41,000 worth of equipment in a certain paper mill which reduced the fiber losses from $160,000 to $30,000 annually.
3. Recovery processes developed in the by-product coke industry which have provided economical methods of utilizing phenol wastes, a most objectionable source of pollution of public water supplies.

Industry needs to be awakened, however, to a realization that utilization of its waste is not only a question of financial return, but also of developing economical methods of waste disposal. While an installation may not result in a substantial financial return, it may provide an economical method of waste disposal.

Although there is room for improvement in methods of sewage treatment, accepted and practical methods have been developed and are in operation. There has been some study in regard to the treatment of certain industrial wastes, but in no instance has an accepted method been developed. Research in the treatment and disposal of industrial wastes is, therefore, one of the primary needs of the present time, and any program for stream improvement which does not take this into consideration is incomplete.

COÖRDINATION OF ACTIVITIES

New organizations or associations to study these problems seem unnecessary, but coördination of existing ones is essential. The administrative agencies should undoubtedly be the state departments of health. Provision for interstate agreements such as have been perfected in the Ohio River and Lake Michigan watersheds is desirable.

An advisory council on which all interests are represented is a valuable asset. Stream pollution cannot be controlled effectively by prohibitory legislation. In fact, such legislation is destructive and inimical to public interests. Legislation should establish an organization supported by ample funds to conduct a constructive, sustained, coöperative program in a study of the problem, both with reference to the effect of pollution upon streams and aquatic life thereof, and methods of waste utilization and treatment. Department of health activities in the various states may be adequately coördinated through the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association.

There should be local committees representative of the different branches of industry in each state to coöperate with the state department of health. Such coöperative programs have already been inaugurated in at least 7 states—Minnesota, Wisconsin, Michigan, Ohio, Pennsylvania, Maryland, and Connecticut. In some instances these local committees have been formed at the request of the state officials, in conferences with representatives of the various branches of industry. Practically every state, however, has either an aggressive chamber of commerce or association of industries.

As representative of the American Paper and Pulp Association, the writer recently assisted in developing an organization through the Associated Industries of Connecticut in coöperation with state officials. The organization in Connecticut provided that the Associated Industries appoint committees representative of their respective branches of industry interested in the problem of stream pollution; the chairmen of these committees then constitute a central committee representative of industry in the state as a whole. Some nine or ten industries of Connecticut have been thus organized. It seems consistent that this policy be followed in other states where industry has not already been organized.

The organization of industry, however, needs to go further than state committees to provide adequate means for interchange of ideas and data. The pulp and paper industry, realizing the national scope of the problem, is organizing its activities and coördinating the work of its local state committees through its national organization, the American Paper and Pulp Association. It is believed that this industry is the first and only one to place a full-time representative in charge of these activities. The National Canners Association, however, has given some consideration to the problem and has coöperated in research conducted in various states.

The work of other industries could doubtless likewise be coördi-

nated through their national trade organizations. The national representatives of the various industries could then constitute a central national committee to act as a clearing house to assemble and disseminate data of general information. This national organization of industry could then coördinate its activities through the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association. In fact it seems essential that such or similar channels of communication and types of organizations be developed if the most economical and practical methods of handling this problem are to be brought about.

SUMMARY

The essence of these remarks may be summarized as follows:

1. *Standard Methods of Water Analysis* should be revised and extended to cover more adequately the analyses of industrial wastes.

2. With proper coördination, existing organizations, including state or other local conferences of sewage plant operators, the American Society of Civil Engineers, Conference of State Sanitary Engineers, and the Public Health Engineering Section of the American Public Health Association, can satisfactorily handle research in sewage disposal.

3. The administrative agencies in control of all stream pollution activities should be the state departments of health, with suitable legislation and financial support.

4. Local state committees representative of the various industries should be developed in each state to coöperate with the state department of health. These local committees should be coördinated through a central state committee representative of industry as a whole.

5. The activities of the local state committees of each industry should be coordinated through the national organization of their respective industries.

6. National representatives of the various industries should constitute a central national committee to coöperate with the Conference of State Sanitary Engineers, Public Health Engineering Section of the A. P. H. A., Izaak Walton League, and others, in the exchange of ideas, collection and dissemination of data, and general coördination of all efforts.

7. Finally, public health officials and others interested in improving stream conditions, both in their local state activities and through their national organizations, should give more definite recognition to industry in consideration of the problem, and industry should be given ample opportunity to express itself regarding the various problems.

Outbreak of Botulism, Westfield, N. Y.

EDWARD CLARK, M. D., FELLOW A. P. H. A.
District State Health Officer, New York State Department of Health, Buffalo, N. Y.

ON December 29, 1928, I received an emergency request from Elmer W. Powers, M.D., Health Officer of Westfield, N. Y., to go with him and Van S. Laughlin, M.D., to see some cases which were puzzling them as to diagnosis.

The two cases which I saw were typical of botulism. Three had died before I arrived, but the histories, given by Dr. Laughlin, indicated that they were also typical botulism. I made a rather brief investigation which revealed the following facts:

A dinner was given at the home of James Dina, Westfield, N. Y., on Christmas day, at about 4 P.M. The company, 24 in number, represented two families living in Westfield and one in Fredonia, and was made up about equally of adults and children. The food consisted of freshly killed chicken, macaroni and cheese, bread, potatoes, green and yellow home-canned string beans.

The following cases had occurred up to the time of my visit:

1. Mrs. James Dina, age 55, first showed symptoms of illness on December 26 at about 4 P.M. She was slightly nauseated at first and vomited a little; later she began to have difficulty in articulation and deglutition, gradually growing worse. When I saw her she could neither speak nor swallow. She complained of difficulty in distinguishing objects. Her pupils were dilated, with sluggish response to light. There was great muscular weakness and an accumulation of mucus in the throat which she was unable to cough up. There was no rise of temperature at any time, but a rather rapid pulse. She died at 6 P.M., December 29.

2. Santa Mella, age 4, living at Fredonia, became ill December 27 early in the morning. She vomited a little, soon became helpless, had difficulty in articulation and deglutition, and an accumulation of mucus in the throat. She died on December 27, at 11 P.M.

3. Josephine Grizanti, age 4, became ill December 27 at 9 A.M., and showed the same symptoms as described. She died December 28 at 10 A.M.

4. James Grizanti, age 22, was taken ill on the evening of December 26. Dr. Laughlin saw him first on December 28 at 5 A.M. He vomited frequently, and was the only one of the cases who complained of abdominal pain. There followed difficulty in articulation and deglutition. He died on December 28.

5. In Sam Dina, age 14, the onset of illness was December 27, about 4 P.M. He had difficulty in swallowing, dilated pupils, with slow response to light. He died three or four days later.

6. Rose Dina, age 9, became ill December 28, about 4 P.M. She vomited at

intervals, had no pain, no difficulty in swallowing, no rise of temperature, a normal pulse, but dilation of the pupils. She recovered.

Two boys in the Grizanti family, Cosmo, 14 years, and Joseph, 18 years, had attacks of vomiting on December 28, about 3 P.M., but no other symptoms.

It was impossible to secure any of the food eaten at this dinner, as it had been thrown out for the chickens. Two cans of beans put up at the same time as those served at the dinner were obtained, and sent to the New York State Laboratory for examination. The report on them was negative.

The Dina family found a can from which beans were served and had not been washed. This was examined by Dr. W. E. Cary of the University of Chicago, who has reported as follows:

> There was not sufficient toxin in the washings from the empty can which we obtained to kill any of our animals by direct feeding. However, after culturing the washings on beef heart media, we secured a very potent toxin which has killed guinea pigs in dilutions of 1:100 when fed by mouth. The pigs controlled with Type A antitoxin did not die, which indicates fairly clearly that there were spores of Type A botulinus remaining in the washings of this can. . . .

That the beans were infected with the *B. botulinus* is further proved by a summary prepared by Dr. Laughlin. All who ate them even in small quantities were ill, and most died. One (Rosa Dina), who denied having eaten beans, was ill with typical symptoms, but recovered. Those who did not eat beans escaped illness. With one exception, none of the patients showed evidence of mental dullness, or rise of temperature. All of them had rapid pulse.

Study of Effect of Environment on Quality of School Work—Germany

IN an effort to ascertain the effect of home environment on school work, a study of more than 800 public school boys and girls, ranging in age from 11 to 14 years, has been made in two cities of Germany. The quality of the child's work was judged by his advancement in school; no intelligence nor other tests were given. Only children of families with a moderate or low income, in which both parents were living, were included in the study.

The investigator found that the lower the economic standing of the family, the poorer the child's school work. For instance, of the children of unskilled workers about 50 per cent were retarded in the lower grades, the proportion being even greater for those in the higher grades. These conditions are attributed by the author largely to faulty hygiene, disease, and physical weakness, which are more prevalent among the poorer families, and partly to inherited lack of ability.—*Ztsch. f. Kinderforsch.*, Berlin, 35, 1: 7, 1929.

Measurements of Efficiency and Adequacy of Rural Health Service*

HARRY S. MUSTARD, M. D., FELLOW A. P. H. A.,
and JOSEPH W. MOUNTIN, M. D.

Director Rutherford County Child Health Demonstration, Murfreesboro, Tenn.; and U. S. Public Health Service, Nashville, Tenn.

THE efficiency and adequacy of a local health service is or should be the concern of four groups: the people receiving the service, the taxpayers who shoulder the burden, the local workers rendering the service, and the state and national health agencies promoting or supervising the local service. To these groups may be added a fifth, the detached students of administration whose critical judgment is of great value. The determination of efficiency and adequacy is more than the application of a performance test. Many criterions must be taken into consideration, the principal of which are: nature and extent of the problem, character of program, service rendered, and in so far as can be measured the results attained.

No program can be considered either sound or satisfactory unless it is based on the needs of the area. Certain problems are more or less common to all areas, among which may be mentioned sanitation, control of communicable disease, and child health; yet the nature and extent of work necessary to handle these satisfactorily varies with the community. Malaria, hookworm, trachoma, industrial diseases and hazards, and the like, may be problems. In the beginning the administrator may obtain sufficient general information to define his problem through a study of morbidity and mortality data coupled with a hasty field survey. Later more detailed information concerning individual citizens and premises should be obtained. Throughout the succeeding years, an analysis of suitability of program to the problems should be made, but it should be based on records compiled by the health organization, from which should be determined not only the actual health status of the area, but also the effectiveness of the methods employed.

Next in importance to an analysis of the problem is the projection

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928

of a program designed to effect its solution. All too often, health departments merely meet situations as they arise or carry on stereotyped programs handed down from predecessors. A high degree of efficiency cannot be attained except when following a charted course. At the present time, scarcely a single rural health organization is sufficiently manned and financed to carry out a complete and balanced program. Other factors enter: certain functions are defined by law and must be performed irrespective of worth until the law can be changed; epidemics and disasters will arise necessitating concentration along certain lines.

In general, the factors guiding program planning should be: the relative need for a given amount or type of service; the ease with which results may be attained; and the greatest good for the greatest number. Sight should not be lost of important factors in public relations such as: popular demand, desire for local service, and the creation of a feeling that the situation is being handled. A bit of the dramatic will lend color, and a paramount issue will stimulate interest. No attempt, however, should be made to enter a field unless a reasonable concentration of service can be attained, since dilution of effort beyond a certain point amounts to nullification.

RECORDS AND REPORTS

It is upon records and reports that measurements in detail must be based, and the importance of this subject warrants considerable discussion. However troublesome these records and reports may seem, there is no justification for neglecting either. Systems now in vogue are burdensome because of detail which serves no useful purpose. One system is usually copied from another, and the chief concern seems to be what might be included rather than what might be omitted. Yet despite this plagiarism, differences exist which render difficult or impossible the compilation of comparable data necessary for analysis and study.

The influence of the hospital and dispensary can be seen in all forms used by welfare stations; field nursing records bear the stamp of the visiting nurse; and communicable disease forms have been handed down by the epidemiologist concerned with investigation rather than control. Reports are even more troublesome than records, since the rural health organization as well as individual workers within the organization are required, as a rule, to render reports to several agencies. Each agency participating in local health work has a special form and no other will satisfy its purpose. This confusion will continue until records and reports find a common origin in

sound public health administration. There are four elements in a complete system of records and reports: (1) basic case records, (2) daily record of activities of individual workers, (3) periodic summary of progress, and (4) annual analysis.

The purpose of the case record is to provide space for entering data which may assist in handling a given case or situation, or which may have value for statistics or study. If this purpose is adhered to rigidly, the form becomes remarkably simple and analysis of the data presented does not become insurmountably difficult. The daily record kept by the individual workers should be merely a record of service and only a key to the basic case record where more detailed description of the service can be found. By the use of a code for the several services, the same form may be used by the different workers. Any complicated system is doomed to failure, and unless entries are made in the field when the work is performed, the data are certain to be inaccurate. The periodic summary should be brief, based on a sampling of activities. It has a twofold purpose: a check on progress, and a concise report of service rendered. Beyond this, it should not go. Any attempt to gain a complete picture by a monthly cross-section is futile. Here, too, the guiding principle should be, what can be omitted rather than what might be included. Its brevity need not be a cause for worry if the right type of annual report is used, and if its form is made known to the local health officer in advance. The annual analysis should constitute the main report of the organization. It should be complete and searching, giving a picture of the problem, the service rendered, the results accomplished, and the money spent.

The question arises as to what should be the common origin of reports and records. It has been stated in this paper that the origin should be sound public health administration. *The Appraisal Form for Rural Health Work* developed recently by a sub-committee of the Committee on Administrative Practice of the American Public Health Association more nearly represents public health opinion than any available document. The corollary, then, is that records be built around the *Appraisal Form.*

APPRAISAL

Appraisal, used in the sense of estimating quantity, quality or value of service, is practiced by interested persons wherever the service is established. Most frequently, it is based on personal opinion, a few going a step further and comparing the work of one area with that of another, or present conditions with past. The assignment of numerical values to various items has been used for many years in

the field of sanitation. More recently this principle has been applied to other health services.

The *Appraisal Form for Rural Health Work* is an attempt to combine the experience of workers in this field. However, any method of appraisal has very definite limitations and there is always the danger that it may become an end in itself rather than a means to the end. Its primary purpose is to measure service rendered; secondarily, its standards of performance may be used as a working plan, but only in so far as the administrator may choose to be guided by the judgment of others should he allow any method of appraisal to shape his program.

Since we possess rather meager information concerning the interrelation of problems and practices under different circumstances, each specific activity or accomplishment must be appraised separately, and possibly with a standard applicable to the particular item in question, but not to any other service or result. Thus satisfactory and correct measurement will be possible only when the rural health problem has been analyzed before projection of the program, when projection of program has been undertaken with certain itemized goals in view, and when records of services and results have been kept in such a manner that the data required for measurement of efficiency or adequacy of service will present in detail how much progress has been made toward the goals previously set up.

ADEQUACY AND EFFICIENCY OF PERSONNEL

In connection with measurements of health service, it should be borne in mind that an organization may be rendering adequate service and yet not be efficient, or the converse. Two entirely different qualities are being rated, and these should, but do not necessarily bear direct relationship to each other. In the A. P. H. A. *Appraisal Form*, for instance, the type and volume of service rendered to the community is the basis of measurement from which a score is determined. In other words, the present form sets forth the kind and amount of service which should be rendered but throws no light on personnel and budget requirements. Those concerned with administration frequently wish to know what personnel is required for the performance of a given amount of service. This information is needed when projecting a budget or a program or when attempting to appraise the work of an individual. Without this information the appraiser cannot definitely state whether a community is receiving full value for the money expended, or, what is more important, whether a low score is due to the inefficient health organization or to the niggardliness of the commu-

nity. At present, no data on performance of individuals working under a wide range of rural conditions are available. Under the circumstances, no statement, nor even a guess, can be hazarded concerning adequacy of personnel or budget or method of measuring the efficiency of individual workers or the organization as a whole.

GENERAL CONSIDERATIONS

Originally, rural health service was a city institution incorporated into an entirely different structure. Programs, policies and criterions are a carry-over. Up to the present time, very little carefully checked data on rural health conditions as affected by health service have been assembled. The meager information available is mostly of the cross-section type and coincidental circumstances are grasped as supporting arguments. There remain to be determined what the results are and how they can be attained.

In spite of its weakness, service rendered forms the basis of most of our appraisal efforts. The measurement of such services will yield true indexes of adequacy and efficiency in proportion to the soundness of the assumption that the prosecution of a particular activity will bring about a particular result. Certainly such appraisal is valuable; certainly a study of service rendered will determine whether or not an organization is engaging in a balanced program according to a somewhat empirical pattern, but endorsed by the unhurried judgment of competent observers. It would be unsafe, however, to allow measurement to depend entirely upon appraisal of service rendered. Possibly, on an annual basis, such measurement is the most satisfactory index of potential accomplishment, but on the other hand, it should be supplemented by studies of such morbidity and mortality rates and trends as may be proved to be safe indexes.

The very nature of the general subject indicates that no satisfactory system of measurement of adequacy and efficiency will, or should be built up as a suddenly completed instrument. What and how to measure will become better understood as real scientific data are accumulated. It must be admitted, also, that in every health program there are certain intangible services and results not amenable to weighing and measuring, but this is no reason for discouragement. Measure and evaluate whatever is amenable to such treatment and it is entirely possible that the measurable factors may be found to bear a rather constant relation to those now considered unmeasurable.

No attempt has been made to set up any new method of evaluation of health service. Rather, this has been a discussion of difficulties and possibilities which seem to be inherent in present units of measure and

factors measured. There is nothing in this treatment of the subject that would warrant conclusions, but the following summary may be significant.

SUMMARY

1. It does not seem practicable at this time to determine or measure all of the indexes of efficiency and adequacy of rural health service.

2. It does seem practicable and desirable to determine and measure such indexes as are amenable to this treatment.

3. An index of accomplishment must represent a specific item where cause and effect may be specifically demonstrated.

4. There appears to be need for accumulation of scientific data substantiating assumption that the prosecution of a given activity will be followed by a specific result.

5. There appears to be need for determination of what mortality and morbidity rates or trends may be accepted as indexes of accomplishment, and what population unit, or number of years' experience, shall be considered as essential for credit of such rates or trends.

6. There appears to be need for determination of specific standards of efficiency for various personnel employed.

7. Measurement of rural health service should be based upon a study of efficiency of personnel, adequacy of service and results obtained.

A Few More Recent Arguments in Favor of Pasteurization

Washington, N. J.—Two hundred and two cases of scarlet fever due to raw milk, 192 of which occurred within 6 days—May 26–31, 1927.

Plymouth, Mass.—One hundred and twenty-seven cases of scarlet fever, 101 of which were primary, occurring on one milk route which supplied raw milk to approximately 250 families. For 5 years previous to this outbreak in a population of some 13,000, the yearly average of scarlet fever had been 12 cases.

Wayland, N. Y.—One hundred and forty-one known cases of septic sore throat, including the proprietors of the dairy—husband and wife. Forty employees in one factory were off duty. Practically all of the victims became ill within 3 days—February 16–18, 1928.

Savannah, N. Y.—Seventy-five cases of septic sore throat, all falling ill within 8 days—March 10–18, 1928.

Lee, Mass.—Nine hundred and fifty cases of septic sore throat, occurring within 2 weeks, with 48 deaths.

Do we need further argument to show the importance of pasteurization?

Some Unsolved Child Labor Problems*

ETHEL M. JOHNSON

Assistant Commissioner, Massachusetts Department of Labor and Industries, Boston, Mass.

AS long as there is child labor, there will be child labor problems—special problems that do not apply in the case of adult workers—that arise from the physical weakness of children, their immaturity, their ignorance, and their helplessness.

One of these problems is the protection of children employed in industrialized forms of agriculture, and this is by no means confined to migratory workers. It is a difficult matter to deal with because of the popular conception that such work is confined to useful tasks on the home farm, doing chores for a neighbor, or earning a few pennies picking berries.

It is not such tasks which constitute the problem. It is where numbers of children are brought together to work under virtually industrial conditions, with foremen or overseers in charge, that the serious problem is created.

Of the thousands of children under 14 and under 16 years of age listed in the federal census as employed in agriculture, a considerable proportion—in some states, such as Massachusetts, the majority—are recorded as employed on other than the home farms. Many of them are working doubtless in the gardens of the Imperial Valley, on the beet fields of the middle west, on the truck farms of the Atlantic coast, and on the tobacco plantations of the southern states and New England.

Although this work is frequently carried on under conditions that at least approximate those in the factory, there is practically no regulation. Some of the states specifically exclude farm labor from the application of the labor laws, thus leaving children as well as adult workers largely without protection.

The failure of most of the state child labor laws to deal with the situation is in part due to the fact that many of these laws were enacted before the employment of children in certain forms of agriculture had developed on an industrial scale.

---

* Abstract of address given at the Convention of the Association of Governmental Labor Officials of the United States and Canada, New Orleans, La., May 23, 1928.

Massachusetts has, in general, high standards for working children. Yet aside from the school attendance laws, there is little protection afforded to the children who work on the onion and tobacco plantations in the western part of the state. There is not even a record of the numbers employed, as the work is carried on mainly during the summer months when the schools are not in session. The youngest children do not even have to be certified for this work.

People in a position to know have estimated that during the height of the season, several thousand children—boys and girls under 16 years of age—are employed on the plantations; and that the majority of these workers are under 14 years of age. As many as 100 are sometimes employed on a single plantation.

There is practically no regulation of working conditions; no limitation of the hours, other than the night work limits for all children under 14 (prohibition of employment before 6:30 A.M. and after 6:00 P.M.); and there is no age limit. Young children are desired for the work on the shade grown tobacco, to pick the lower leaves that grow close to the ground.

It is very hot and sultry under the tents during the months of July and August. There have been instances reported where horses working under the tents have died as a result of the excessive heat. That suggests what the conditions may mean in the case of young children, and there have been stories of children overcome by the heat and humidity.

There are, from time to time, reports from people in the vicinity of the plantations of moral hazards in this work, of bad working conditions, long hours, and sometimes of harsh treatment by the overseers. In the absence of definite regulations it is not possible to say to what extent such conditions, and others injurious to children, may exist.

There are difficulties in the way of securing legislative regulation of child labor in agriculture. It should not be impossible, however, to frame legislation which will permit regulating the employment of children in forms of agriculture which have become industrialized, and to check abuses wherever found, without interfering with the legitimate work of boys and girls on their parents' farms.

Safeguarding the health of children entering or already in industry is a matter which deserves more attention than it has yet received. Although the majority of the states have some provision for health certification for young children before they are permitted to enter employment, a number make no provision. In the case of some of those that do, the requirement for an examination is optional with the official who issues the permits.

Massachusetts is listed as one of the states where the requirement is mandatory. There is, however, a loophole in the health certification law which very greatly impairs its effectiveness. The law provides that every child between 14 and 16 years of age who wishes to go to work must present a health certificate from a physician who certifies that he has thoroughly examined the child and found him in sufficiently sound health and physically able to perform the work for which he is applying.

It was intended that this examination should be made by the school physician. By slipping in the words " or family," it was left for any physician to make the examination and issue the health certificate. In its operation, " family physician " means any physician who will sign the certificate, the result being that if a child is refused a certificate by one he has simply to go to another, until he finds one who will sign. The protection intended by the law is thus largely destroyed.

In some of the cities of that state, the work is assigned to one of the school physicians appointed for this purpose and is conscientiously performed. In other places, however, there is little attention given to it; and the admission is frankly made that the work is not being properly done.

A recent check-up made for a private agency, covering a representative group of cities and towns, showed that in many localities the work is superficially done; that in many places there is no standard for the examination; and that practically no children are rejected as physically unfit.

Many who are interested in the protection of children would like to see the responsibility for this work placed definitely with the school officials as originally planned. They would also like to see a properly qualified physician put in charge, given an adequate salary, and allowed time to visit industrial establishments to learn about the occupations in which children are employed.

The health certification of children entering industry has a direct bearing upon their health after they have gone to work. Aside from the provisions of the statutes of some of the states excluding children under certain ages from specified occupations presenting definite health hazards, little attention is given to the health of children once they have become wage earners.

There is need for more studies dealing with the health of working children, the effect of industry upon young children, and the effect of certain kinds of employment, so that there may be intelligent revision of the lists of those prohibited, in order to cover new hazards that have arisen since the original lists were adopted. Such studies should help

to indicate the kinds of employment that are safe, and the kinds from which children with certain physical defects should be excluded. They should tie up with the health certification for children entering industry and show how that important initial work can be strengthened and improved.

Prevention of accidents to employed children, and to all industrial workers, has received more attention than the other problems mentioned. A good deal has been accomplished, but much remains to be done. As long as boys and girls are maimed in industry, and young lives are sacrificed, the problem is not being met.

The Massachusetts child labor laws make careful provision to exclude children from industrial hazards. Prohibition against employments involving accident hazards extend to boys and girls up to 18 years of age. The Massachusetts State Department of Labor and Industries is given authority to add to the lists of prohibited employments for minors under 18 and under 16 years of age; and to exclude minors from any specific machine where there appears to be an accident hazard. This authority to act in individual instances is utilized from time to time. The general authority, however, to add to the list of prohibited processes has never been used by the present department; and only in 3 instances was it used by the former State Board of Labor and Industries.

Although the list of prohibited employments for children under 16 years of age is fairly comprehensive, and includes something like 20 different kinds of machine work, boys and girls below this age are still permitted to work " in connection with " some very dangerous machines. One of these is the spinning mule. Boys of 14 and 15 are frequently employed as back boys on the mules. Sometimes very serious, even fatal accidents occur. There was one very terrible accident where a boy of 14 was caught between the heavy steel carriage and the breast beam and crushed to death. Another boy of the same age in a similar accident escaped with a badly broken leg. An older boy, cleaning the machine while it was in operation, was caught and his head crushed. Still another, winding the sticks while the carriage was running, received a double fracture of the jaw and lacerations of the head and face.

One of the most dangerous machines in industry, as far as children are concerned, is the freight elevator. Most of the fatal accidents to boys under 16 years of age in Massachusetts industries occur " in connection with " freight elevators. The majority of the non-fatal elevator accidents to minors involve boys under 16.

Of 121 elevator accidents to minors investigated by the present

Department of Labor and Industries, 68 were sustained by children under 16, and of 23 fatal elevator accidents, 14 occurred to boys under 16. Of 6 fatal accidents to children under 16, investigated by the department in 1926, 2 were " in connection with " freight elevators. In one case a boy of 13, illegally employed in an industrial establishment, was crushed to death.

It should be noted that the Massachusetts law prohibits the employment of minors under 16 years of age " in operating, cleaning or repairing freight elevators." It does not, however, prohibit the employment of such minors " in, on, about, or in connection with " freight elevators, and it is in work that comes under this classification that most of the accidents occur.

A few states are trying to prevent, or at least reduce, industrial accidents to children by requiring extra compensation in the case of those injured when illegally employed, making this a direct penalty upon the employer against which he is not permitted to insure. The majority, however, have no such provision. Some even specifically exclude from their compensation laws those injured in the course of illegal employment. In Massachusetts, the question whether illegal employment is covered by the compensation laws has not been decided by the courts.* In the absence of a court opinion, the Department of Industrial Accidents grants the award.

The Massachusetts law makes no specific provision for an additional award in the case of injuries to children arising out of illegal employment. There is a provision to permit an extra award in the case of accident, whether to adult or minor, due to the wilful misconduct of the employer or his agent. In only a few instances has such an award been made, and in view of a court opinion it is of little practical value.

All of the problems mentioned present difficulties, but they are not insuperable. It is not unreasonable to look ahead to the time when legislative protection shall be given as a matter of course to all child workers regardless of the nature of their employment; when child labor in agriculture, as well as in factories, will be covered by regulations requiring fair working conditions; when adequate provision will be made through enforceable regulations to safeguard the health of children going into industry, and after they are in; when laws that were excellent at the time of their passage, but have gotten behind the times, will be revised to meet changing industrial conditions.

* An opinion of the Supreme Judicial Court of Massachusetts, May 29, 1929, apparently establishes the right of compensation in case of injury arising out of illegal employment.

Iodine in Water, Food and Urine

H. W. CLARK, FELLOW A. P. H. A., AND GEORGE O. ADAMS

Chief Chemist, Massachusetts Department of Public Health, Boston, Mass.; and Chemist, Lawrence Experiment Station, Lawrence, Mass.

MUCH has been written of late years in America concerning iodine in water, and its introduction into public water supplies which are deficient has been strongly advocated by some as a public health measure. Certain cities and towns have, moreover, adopted this procedure in an attempt to prevent or minimize thyroid troubles. During 1925 and 1926 the iodine in about 100 of the public water supplies of Massachusetts was determined and found to vary from none to 6.33 parts per billion. These results were given quite fully in the reports of the Department of Public Health of Massachusetts for 1925 and 1926. A more complete study of iodine in Massachusetts waters and elsewhere was given in a paper by H. W. Clark.[1]

In all this work attention has been called to the fact that we are not dependent upon water for iodine, as many vegetables and grains contain it in large amounts, and sea fish, especially certain species, are great carriers of iodine, as are marine growths, seaweeds, mosses, etc. Certain determinations of iodine in food have been made by the authors and by others. Some of this work has been summarized by the Bureau of Fisheries of the U. S. Department of Commerce in its bulletins. Among the many determinations of iodine in food made at the Lawrence Experiment Station may be given those shown in Table I.

TABLE I

IODINE CONTENT

	Iodine Parts per Billion		
Soft-shell clams	1,012	1,152	—
Quahaugs	197	130	205
Flour	16	9	—
Fresh codfish	1,056	946	—
Milk	17	—	—

It will be noticed how large the iodine content of these foods is compared with that of the Massachusetts water containing the greatest amount, namely, 6.33 p.p.b. As all these results made it evident that water furnishes only a small part of the iodine required by the human

body, it was decided to make some determinations of the excretion of iodine in order to show the comparative amounts taken in through water and the amounts excreted.

During 1928, 48 analyses were made of the urine of different individuals. The highest amount of iodine found was 210 p.p.b. and the lowest 5 p.p.b., the average being 41, or more than 6 times that found in the richest iodine-bearing water of the state. It was also found that there was a great variation in the amount of iodine in samples from different individuals, some giving uniformly higher results than others. It was also noticed that the amount of iodine was lower during warm weather. The average amount in the urine from 7 persons during April, May, October and November was 66 p.p.b., during June, July, August and September, 28 p.p.b. The low summer results are probably due to greater consumption of water at this season and dilution of the iodine taken in with food.

From the results of this work it is evident, in Massachusetts at least, that only a small percentage of the iodine entering and passing through the human system is obtained from water, and it is probable that the introduction of iodine into water supplies is more or less futile compared with selecting or preparing food, salt, etc., so that an amount of iodine sufficient for the needs of the body is taken in.

The method used by us for determining iodine in water has been given in the reports and article referred to. When this work was begun, however, it was found that there was no adequate or reliable method for the determination of iodine in urine; hence the following was developed at the Lawrence Experiment Station:

All organic matter must be destroyed, and owing to the large amount in urine the determination of iodine is much more difficult than in a sample of water. The usual method of burning the organic matter with oxygen presented so many difficulties that a different procedure was tried:

After evaporating 2,500 to 4,000 c.c. of urine with 10 gm. of caustic soda to the consistency of a thick syrup, it was transferred to a small iron pan, about 20 gm. more of caustic soda added, and the mixture heated slowly until fumes ceased to come off. This destroyed most of the organic matter at a comparatively low temperature. The resulting black clinker was ground in a laboratory hand mill and allowed to stand over night in a beaker with about 200 c.c. of alcohol to extract the iodides; the alcohol was then decanted through a filter, the residue washed by decantation several times with alcohol, finally placed upon the filter and again thoroughly washed with alcohol. A large part of the alcohol of the filtrate was then distilled off, the residue evaporated

nearly to dryness with 3 gm. of caustic soda in a nickel dish, the dish then heated slowly until the organic matter extracted was broken up, the volatile portion driven off and the remainder present as free carbon. The fusion was then dissolved, filtered, evaporated to a small volume, and a drop or two of approximately 1/10 normal arsenious acid added to reduce the iodates. The solution was then acidified with sulphuric acid, transferred to a separatory funnel and a few drops of strong sulphuric acid saturated with sodium nitrite added to liberate any iodine present. The iodine was then extracted with purified carbon tetrachloride and the amount present determined by comparison with a standard solution of iodine in carbon tetrachloride in a Dubosq colorimeter.

This procedure gave check results on duplicate samples and showed an average recovery of 75 per cent on known amounts of potassium iodide added to urine and carried through the regular procedure. This may appear to be a low recovery but it must be understood that the amount of iodine in the average urine analysis was only about 0.02 mg. or 0.00002 gm.

Where Automobile Accidents Occur

AN interesting study of fatal automobile accidents in New York State has just been published by J. V. De Porte, Director of Vital Statistics in the New York State Department of Health. This shows that in 1927 out of a total of 2,555 deaths due to this cause, 1,091 occurred in the City of New York, and 1,464 in the rest of the state. Expressed in rates per 100,000 of population this shows 18.3 per 100,000 killed in the city and 26.6 in the rest of the state. In order to visualize the magnitude of these rates it may be well to compare them with the death rates from some of the commoner causes of death in this city. Thus during the past ten years:

Deaths from Typhoid Fever—have averaged	2	per	100,000
Deaths from Measles — " "	7	"	100,000
Deaths from Scarlet Fever — " "	2.5	"	100,000
Deaths from Diphtheria — " "	13.6	"	100,000

Of the 1,464 deaths, 655 occurred in urban districts and 809 in rural districts.

These are surprising figures. It is probable that much of the high fatality in rural districts is due to excessive speed and carelessness engendered by the feeling that driving in the open country is free from danger. The figures here presented should serve as a warning, and should lead drivers to exercise the same caution in driving in the country that they do when worming their way through crowded city streets.—*Weekly Bull.*, City of New York Dept. of Health, June 8, 1929.

Disposal of Phenol Wastes from By-Product Coke Plants*

F. W. SPERR, JR.

Director of Research, The Koppers Company, Pittsburgh, Pa.

THE growth of the by-product coke industry in the United States has been phenomenal. Fifteen years ago, 75 per cent of all the coke was manufactured by the old beehive oven method in which the by-products were entirely wasted. During the first 6 months of 1928, 90 per cent of the coke in this country was made in by-product ovens. In 1913, about 17,000,000 tons of coal were coked in by-product ovens in the United States. Then came the war, in which the vital necessity of coal by-products for national defense was so forcibly demonstrated and so quickly and actively recognized that in 1918, 37,000,000 tons of coal (more than double the annual amount just before the war) were coked in by-product ovens.

We have the largest by-product oven installation in the world at the plant of the Carnegie Steel Company at Clairton, Pa., coking about 10,500,000 tons of coal per year, or nearly as much as the total of all the by-product coke plants of the United States 15 years ago. The annual capacity of all the by-product coke ovens in this country is more than 85,000,000 net tons of coal.

The growth of this great, new national industry has had very little public notice. It is principally a servant of the iron and steel industry and the gas industry. Its products reach the public through secondary and tertiary agencies such as gas companies, coke dealers, chemical and pharmaceutical works, fertilizer manufacturers, motor fuel distributors, tar product companies and a great variety of others. Most of the manufactured gas used in the United States is produced either directly from by-product coke ovens or from coke made in these ovens.

THE PHENOL PROBLEM

The phenol problem as it exists today, and in so far as it may be caused by by-product coke plant wastes, has been created largely by the rapid growth of the industry and by the introduction of the chlorination of public water supplies.

* Excerpts from paper read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

The first by-product coke plants that had to deal with the phenol problem were owned by iron and steel companies and produced substantially all of their coke for blast furnace purposes. Such plants could and did adopt the expedient of using the phenol wastes to quench the coke. The solution of the problem became much more difficult with the rapid introduction of plants for making domestic coke, for which the practice of quenching with phenol wastes is not feasible.

In considering the phenol problem as it exists today, from the standpoint of the by-product coke industry, it is important to consider the following points:

1. Although the individual plants are rather widely dispersed, most of them are so located as to affect three important drainage areas; thus, 35 per cent of the by-product coking capacity of the United States is located on the Ohio River drainage area; 16 per cent is located around the lower end of Lake Michigan; while 16 per cent drains into Lake Erie, chiefly near Cleveland and Buffalo.

2. Some other solution besides coke quenching must be found to solve the problem for those plants which sell their coke for domestic purposes.

It should be stated at this point that there is every reason to believe that the phenol problem has been solved so far as giving ample protection to the communities in the Ohio River drainage area is concerned. The solution, so far as this district is concerned, has been found almost entirely in the coke quenching method. Although this remedy has secured adequate protection to the public, it is not regarded as satisfactory so far as the industry is concerned, and a great deal of work has been done, and a great deal of money has been and is being spent to find some better method which will protect the public and which will have fewer technical disadvantages.

The extraordinary difficulty* of the phenol problem is proved by the enormous amount of work that has been done on it not only in the United States, but in England, Germany, and other countries. The problem is of serious concern in the crowded industrial districts of western Germany, and visits have been made to this country by many German engineers for the purpose of inspecting the methods that have been developed here. The present situation in America may be summed up by saying that public water supplies can now be adequately safeguarded by certain methods that have been developed. Although much remains to be done toward improving these methods and lowering their cost of application, there is every reason to believe that the problem will shortly be regarded as solved, not only from the standpoint of the public, but from the standpoint of the industry. All pos-

* This difficulty is emphasized in recent German technical literature on the subject. (See D. H. Wiegman, *Glückauf*, Mar. 31, 1928, p. 397.)

sible credit should be given to the very fine spirit of coöperation that has been displayed by the health departments of the different states affected. This coöperation has been responsible for the very rapid progress that has been made—a progress much more rapid than is generally realized and which would be greatly hampered in the absence of such coöperation.

OCCURRENCE OF PHENOL IN BY-PRODUCT COKE PLANT WASTES

In speaking of phenols from the standpoint of waste disposal, we refer to all chemical substances which give the so-called phenolic taste in chlorinated water. Thus, we mean not only phenol itself (C_6H_5OH) and the cresols and bodies of similar character, but also benzol and derivatives of benzol. All of these substances occur primarily in the gas and tar evolved when coal is coked in a by-product oven. Any water which comes in contact with such gas or tar will dissolve out a little of the phenols, and any water which comes in contact with the benzols in the benzol recovery apparatus will carry away enough of these to be objectionable. The sources of the phenols in by-product coke plant wastes are therefore as follows:

1. The gas liquor or weak ammonia liquor which has been condensed or scrubbed out of the gas in contact with tarry matter
2. The so-called final cooler water or water into which the gas has been brought directly in contact for cooling purposes
3. Steam condensate from the distillation apparatus in the benzol recovery plant and other water which has come in contact with benzol
4. Miscellaneous spillages and floor and ground drainage

ECONOMIC CONSIDERATIONS

There is apt to be very serious misconception as to the possible income that can be derived from the recovery of phenols from ammonia still waste. Many non-technical people, interested, as all of us should be, in the subject of stream pollution and having heard of the great values that have been found by some packing houses in the working up of what was formerly refuse, or by some chemical company in developing what was formerly a waste product, have hastily assumed that the same possibility applies to any plant waste.

Now the fact is that one of the serious difficulties of the problem is the very small quantity of phenols that can be recovered. With a phenol content of a little over 2 gm. per lit. of still waste, there will be about 0.5 lb. of phenols in the waste produced from one ton of coal. Most of the by-product coke plants that have to deal with this problem are of moderate size. The Clairton plant of the Carnegie Steel Company is in a class by itself and there are only a few plants handling

more than 3,000 tons of coal per day. The majority of by-product coke plants handle much less than this—1,000 tons per day would be a fairly typical figure. Such a plant would produce about 500 lb. of phenol per day in the ammonia still waste. The value of this is problematical. It should be remembered that it is crude phenol and would require certain refining to make it suitable for most purposes. Four cents per pound might be considered a possible value. At this price, if all the phenols in the still waste from a 1,000 ton plant could be recovered, they would have a value of $20 per day. This is a very slender margin for the operation of any process. The majority of by-product coke plants would be well satisfied if the income from any phenol recovery process would just balance the costs.

METHODS OF PHENOL RECOVERY OR ELIMINATION

A vast amount of experimental work has been done with the object of extracting and recovering the phenols in the gas liquor or ammonia still waste, or of eliminating or destroying it. In our laboratories, the reactions of the phenols with literally hundreds of substances have been examined under various conditions. There is always the possibility that some practical process may be discovered for the removal of the phenols by chemical reaction, but at present the most successful and the most promising processes are based on the employment of physical or biological means.

The processes which have reached large-scale operation may be classified as follows:

1. Disposal by Complete Evaporation:
   a. Evaporation of gas liquor
   b. Evaporation of still waste
      i. On hot coke
      ii. On blast furnace slag
2. Preheating Ammonia Liquor Entering the Ammonia Still
3. Extraction of Phenols with Solvents:
   a. Treatment of ammonia liquor with solvents
   b. Treatment of ammonia still waste with solvents
4. Removal of Phenols with Solid Adsorbents
5. Biological Treatment:
   a. By mixing with sanitary sewage
      i. Untreated sewage
      ii. Activated sludge process
      iii. Imhoff tank process
   b. Treatment on inoculated filters

In most cases, the plants producing phenol wastes are not conveniently located with respect to sewage disposal systems; but the bacterial method of phenol elimination may still be employed by re-

course to the so-called bacterial filters. These consist of beds of porous material—usually coke—inoculated with the phenol destroying bacteria by admixture with manure, sewage, activated sludge, Imhoff tank sludge, etc. The ammonia still waste must be clarified and diluted to such an extent that the bacterial action will not be inhibited or destroyed. A freshly inoculated bed appears to be quite sensitive to an excess of still waste; later, in some manner, the bacteria become more resistant toward the phenols and the proportion of still waste may be increased. The diluted still waste is sprinkled over the surface of the filters and percolates through the inoculated mass, which is preferably aerated.

The pioneer investigations of the treatment of ammonia still waste on bacterial filters were made by E. Frankland and H. Silvester[1] about 24 years ago. They studied the sewage disposal system of Oldbury, England, which consisted of large contact bacteria beds handling city sewage, with which was mixed as much as 9 per cent of ammonia still waste. Later, experimental bacterial filters were installed in England, Germany and America, for the direct purpose of ammonia still waste disposal. The Bradford Road Gas Works, Manchester, England, began using the bacterial filter for this purpose in 1908, and continued the practice for at least 6 years with apparent success, although in 1923 the process was still considered in the experimental stage in England, as shown by the extensive discussion in the *1923 Report of the Alkali Works Inspectors.*

Important work in the application of bacterial filters was done by Ralph L. Brown of The Koppers Company's Research Laboratories.[2] Brown found it desirable to mix humous material, such as peat, with the coke packing, and introduced the mechanical aeration of the filter bed. Instead of employing fresh water for dilution, he recirculated a requisite amount of the treated waste for this purpose. This recirculation is valuable in conserving the bacteria which otherwise would pass out of the system with the diluted waste. With this dilution by recirculation, the beds can be operated practically continuously, one apparatus on a laboratory scale functioning continuously for a year without change.

Present opinion in regard to the application of the bacterial filter under average American conditions is that it is too expensive in comparison with other methods for the elimination of the bulk of the phenols from ammonia still waste. It requires a large ground area (according to Brown, one cu. yd. of filter bed will handle 10 to 20 gal. of ammonia still waste per 24 hours) and the expense of installation is considerable. No bacterial filters have yet been installed on a large

scale in this country, and a single modern large-scale installation in the Emscher District in Germany has been found very expensive to operate. Experts, both in this country and in Germany, believe that the bacterial filter will find application in those cases where the bulk of the phenol is removed by some other method, where conditions make it absolutely necessary to eliminate the last traces of phenol, and where no sewage disposal plant is available for this purpose.

A process has recently been developed by The Koppers Company for the removal and recovery of the bulk of the phenols from the ammonia liquor in connection with the operation of the ammonia still. This is accomplished by taking the hot liquor from the bottom of the free section of the still and pumping this liquor over a scrubber through which a mixture of steam with air or other gas is circulated. The phenols pass into the hot gas and steam while the liquor runs back to the lime leg of the still. The mixture of gas and steam carrying the phenols is then treated in a second scrubber with a solution of caustic soda, which removes the phenols as sodium phenolates. The gas and steam mixture is then recirculated by means of a fan back to the first scrubber. The sodium phenolate is withdrawn from the second scrubber and treated in the usual manner for the recovery of the phenols.

This process, on a large experimental scale, has shown very high efficiency in the removal of the phenols; and in regular operation, over 95 per cent of the phenols are being eliminated. Two large plants are being constructed, one of which is just about to be put in operation at the present writing.

SUMMARY OF PRESENT STATUS OF PHENOL REMOVAL

The writer's personal view as to the application of the various methods that have been developed for the disposal of phenol wastes from by-product coke plants may be summarized as follows:

1. All phenol bearing wastes, with the exception of ammonia still waste, may be handled by installing suitable recirculating and intercepting systems so that no phenol from these sources need reach any public water supply.

2. The cheapest and most satisfactory method for ammonia still waste disposal consists in mixing the waste with ordinary city sewage, provided a sufficient amount of sewage is available.

   a. In cities having no sewage disposal systems, simple mixture with raw sewage will suffice to a certain extent, provided sufficient dilution or time of contact can be had. In these cases, it would be well to consider the installation of a sewage aeration system as this would greatly facilitate the destruction of the phenol.

   b. In cities using the activated sludge system of sewage disposal, a volume of still waste equivalent to 50 parts of phenols per million parts sewage

can be treated with certainty, and it is probable that a much larger proportion can be safely treated.

c. In cities equipped with Imhoff tank systems of sewage disposal, ammonia still waste properly clarified can be added either to the raw sewage or to the tank effluent; and if the effluent is suitably aerated, the phenols will be destroyed. We have not sufficient data as to the proportion of still waste that can be handled in this way, but it is probable that a proportion of 1 part still waste to 10 parts sewage may be safely handled, and Dr. Imhoff states that much higher proportions can be used.

3. Where the required amount of sewage is not available, the ammonia liquor should be treated for the removal of the bulk of the phenols; and this treatment should be followed, if necessary, by mixing the still waste, with its small remaining phenol content, with sewage, or treating it on bacterial filters. In most cases, the removal of the bulk of the phenol from the ammonia liquor will be sufficient without further treatment of the still waste.

4. The disposal of ammonia still waste by using it for coke quenching is available as an emergency method except for plants producing domestic coke; but although it offers adequate protection to water supplies, it is unsatisfactory for many technical reasons and will doubtless be superseded by other methods.

Regulations Governing Public Swimming Pools

THE following regulations governing public swimming pools were adopted at the regular monthly meeting of the Maryland State Board of Health held at the headquarters of the State Department of Health in Baltimore, June 18. The regulations became effective at once. They apply to any swimming pool used for a period of 6 days or longer and accommodating at any one time 10 or more persons.

1. No swimming pool shall be operated without a permit from the State Board of Health, or such local health authority as the State Board of Health may designate. Application for such permit shall be made in writing, upon forms provided by the Department of Health or the properly constituted local authority, stating the exact location of the existing or proposed pool, the approximate number of persons whom it is to serve, the proposed source of water supply, the methods of pool water purification to be employed and the sanitary conveniences to be provided. The form in each instance must be filled in sufficiently to constitute a complete description of the pool and the method of its operation.

2. Before the construction of any natatorium or swimming pool is begun, the plans and specifications for such structure shall be submitted to the State Department of Health or the properly constituted local authority for approval and a permit. The acceptance of a permit shall be construed to indicate that the applicant has read and accepted such rules of operation and maintenance as have been formulated by the State Department of Health under this regulation.

3. All bathing places shall be open for inspection by authorized health officials at all times when the place is in operation.

4. Health officers shall have the power to order reasonable changes relative to improving the operation and sanitary conditions of swimming pools and their surroundings, and, if deemed necessary, to close a pool until the conditions are approved by the State Department of Health.

5. All pools must be supplied with water which meets the minimum requirements of the State Board of Health.

FEDERAL HEALTH CORRELATION

A NEW bill for the coördination of federal health activities was introduced into the 71st Congress on May 20, 1929, by Representative James S. Parker; and a companion measure was introduced by Senator Jones in the Senate as S. 1195. This new bill differs somewhat from that passed by the last Congress and vetoed by President Coolidge, but is the same in its essential particulars.

The new Parker Bill (now H. R. 3142) would empower the Secretary of the Treasury, when requested, to detail officers or employees of the U. S. Public Health Service to coöperate in the health work of any executive department or independent establishment. It would also allow the Surgeon General to detail personnel to educational and research institutions and to extend the facilities of the Service to outside scientists. The establishment of additional divisions in the Hygienic Laboratory for this purpose is also authorized.

A commissioned status for sanitary engineers, dental officers, and other non-medical scientific personnel is provided—the alleged unconstitutional features of the former bill in this respect having been surmounted by vesting the appointment solely in the President, with the advice and consent of the Senate. The number of such appointments is, however, restricted to not more than 110.

The Surgeon General is given the same rank as the Surgeon General of the Army, and a new rank of medical director is created to correspond to that of Assistant Surgeon General, though the latter title would be continued for chiefs of divisions. Promotion would hereafter be the same as in the Army Medical Corps.

No provision is made in this bill, as was in the former one, for a Nurse Corps in the U. S. Public Health Service. Authorization for expansion of the Hygienic Laboratory has also been omitted, as that

is taken care of in another bill, H. R. 3143, introduced by Mr. Parker, for a National Institute of Health. This is the same as the Ransdell Bill of the last session, which passed the Senate. Mr. Ransdell has reïntroduced it in the Senate as S. 1171.

The new Parker Bill provides for enlargement of the present advisory board of the Hygienic Laboratory into a National Advisory Health Council, with five additional members appointed from the public health profession.

This is, of course, an excellent piece of legislation, as was the other bill which was adopted, but vetoed on the advice of the former Director of the Budget. Both the director and his chief are now out of office and the bill has good prospects of becoming a law. Sanitarians can aid in the repassing of this valuable measure by communicating to their senators and representatives their wishes that it pass.

THE PROBLEMS OF BOTULISM

THE occurrence of an outbreak of botulism is still capable of exciting general interest in the causative food and other factors incident thereto. The original report of the California Botulism Commission[1] is now a number of years old. The facts elicited by this commission do not appear to have been generally followed by home canners, since outbreaks continue to occur. These outbreaks are usually accompanied by a serious case mortality rate, and an effort to reduce these preventable fatalities should be immediately made. The preservation of food by heat, as well as the newer methods by cold, is a technical procedure of the first magnitude. The chemical reaction of the food, the consistency of the product, the size of the container, the original soundness of the material, the cleanliness of the packer, and, finally, the source of the bacterial contaminant with its thermal death time and point, cultural and growth possibilities with the production of poisonous substances, all play their part. Therefore, the preservation of food cannot be legislated into safety, but the general public can be educated to accept and use approved methods.

Fortunately, many universities, notably, Harvard, Stanford, Chicago and California, have interested themselves to the end that many facts have been ascertained and applied to canning. Apparently, the greatest benefactors of this unheralded but remarkable research have been the commercial canners of foods. This is shown in the absence during the past few years of outbreaks of botulism due to commercially canned products.

Recently, the *Journal of the American Medical Association*[2] very rightly sounded a note of warning to the home canners because of con-

tinued outbreaks in various parts of the United States. The methods to be adopted to make home canning safe are problems that should be met. There is now available enough information to make a start at least to do this, and official governmental and health agencies should at once adopt a program. This program should primarily be educational. There should not be issued general orders of one type only to have them withdrawn because of subsequently proved impracticability. There appears to be no doubt that certain food products are ordinarily safe from visible spoilage yet may be toxic. Again, there are foods whose acidity would preclude bacterial growth in the majority of instances. Likewise, there may be added to many foods certain inhibitory substances like salts or acids that retard the growth of spores like *B. botulinus*. It is advisable that a committee of qualified persons be appointed to study and report on the safety of the preservation of food, particularly as now practiced in the home, and to lay plans for its future safety.

PROGRESS IN CANCER

WITHIN the last few years there has been a notable advance in our understanding of cancer—not that we are materially nearer a knowledge of the specific cause, if there be one, of that disease, if it be a disease; but there has been distinct progress in the recognition of cancer as a problem which must be attacked in a different way than has hitherto been thought necessary. Instead of being looked upon as a private matter between the patient and his physician, it is now regarded as a subject calling for community action.

Health departments no longer give attention to cancer merely as a detail of vital statistics and as a subject for occasional notice in their periodicals. Its inclusion in the *Appraisal Form*[1] means that from now on the adequacy of health programs will be judged in part by what is done in investigating the prevalence of cancer; in providing for the diagnosis of early and curable cases; and affording proper treatment for the sick, both as to medical attention and nursing.

The broad plan of attack which is being made by the Massachusetts Board of Public Health is being watched with the greatest interest, embodying as it does a definite and continuous campaign of public instruction and the maintenance of clinics in all parts of the state, not to speak of a special cancer hospital.

Within the last three years there have been two international cancer conferences, one in America to consider the practical applications which should be made of existing knowledge, and the other in London on the subject of research.

The literature devoted to cancer has increased enormously during the last five years, every conceivable aspect of the question receiving its share of attention. The daily press, instead of avoiding the subject, as was formerly customary, eagerly prints as news acceptable to its readers whatever appears authentic and of value. The publication of a series of sixteen informative articles without any news value whatever in over five hundred newspapers was a public service which was without precedent and is not likely soon to be repeated for any other cause.

Although there has been distinct progress in the recognition of cancer as a great social, medical and public health question, the scientific solution of its causation awaits further study. Research in many directions and by specially qualified persons is now being actively prosecuted all over the world. The expectation is not that a single and complete solution can be found for all the cancers which occur, since they appear in a great variety of forms and grades of malignancy, but it is believed that by separating cancers into small groups or studying them individually, the chain of events which leads up to the development of the cancer cell may eventually be worked out.

BOOK REVIEWS

REVIEWS of scientific books present one of the most difficult problems of an editor. There is an overwhelming deluge, and some publishers are very insistent in asking for reviews of those they send in. A good review is an advertising asset, and not many years ago certain publishers demanded favorable notices at the cost of cutting the journals from their free list. Happily there has come about a great change in this respect. While publishers of course wish favorable reviews, protests against unfavorable ones are not common—at least in our experience. In a recent article the well known editor of *Science*[1] tells of an instance in which the sales manager of a university press canceled advertising on account of a notice to which he took exception.

Many factors must be taken into consideration in the reviewing of books. The first is the selection of those which are suitable for, and

worthy of, review in the particular publication, this depending to a great extent on the character of the journal and the class of readers which it reaches. It goes without saying that considerable latitude is possible, since there is much overlapping. A scientific journal must at times consider even novels and popular books, either to commend them for general reading or to condemn their false teaching. Our JOURNAL must consider books which are of interest and value to its varied membership.

When a book has been selected, to whom shall the review be entrusted? Preferably to some specialist on the subject of which it treats. In general, this seems the wisest course, but at times leads to unfair or too exacting criticism. Unrequested reviews are apt to be favorable, written by some friend of the author, though they may also come from scientific adversaries. The great object of an editor must be to obtain a fair and impartial criticism, devoid of personalities, adhering closely to the material presented, taking into consideration the claims made by the author, and to some extent those of the publisher. It must always be remembered that reviews are useful to readers who may not have opportunities for the critical selection of their reading matter. Many buy their books on the strength of reviews in standard journals. Authors generally appreciate fair reviews, and consider the criticisms in the preparation of second editions.

The editor must always have in mind the reputation of his journal for accuracy and fairness. A favorable opinion of a poor book reacts upon a journal, through loss of confidence on the part of readers. The reviewer must always be accurate in his statements and able to back them up by quotations, with page and line. Reviews should stick to the subject matter of the book. Too many reviewers seize the opportunity to write essays on some individual fad. Such contributions are articles rather than reviews, and often have only a remote connection with the material submitted.

There is great diversity of opinion as to the value of book reviews. Some hold that they are of interest to only three parties—the author, publisher and reviewer; others, that the larger part of a journal should be devoted to reviews. Such opinions are reflected in the practices of different editors. In our own JOURNAL, as much space as possible will be given to reviews. Writers will be selected for their special qualifications, and are urged to remember that the essentials of a good review are honesty, knowledge of the subject, clarity of expression, and brevity.

ASSOCIATION NEWS

58th Annual Meeting, A. P. H. A.
Minneapolis, September 30 - October 5
Registration Headquarters — Exhibit Hall, Minneapolis Auditorium

The Executive Board Proposes Association Changes

SHORTLY after the last Annual Meeting, the President of the A. P. H. A. requested the Committee on Cooperation, Development and Finance to study the services rendered by the Association to its members and to the cause of public health generally; to take stock of the effectiveness of its organization, and of its administrative and financial methods; and to devise ways and means of realizing the still undeveloped potentialities of the Association for fruitful activity. This organization like all others must be prepared for change and expansion to keep pace with scientific progress and the changing ideals in public health work. To achieve these purposes, the Committee on Coöperation, Development and Finance, with the approval of the President and with expert guidance, proceeded to analyze and study the Association.

In this effort the committee aimed to formulate proposals which would develop our activities in accordance with a carefully conceived, long-visioned and well-organized plan, which would simplify and strengthen our administrative machinery and would effect economies where possible, and at the same time define the responsibilities of our officers and the administrative staff in achieving our major objectives.

The facts and the observations that developed from these studies were embodied in large part in a report prepared by a consulting economist whom the committee had engaged to aid it. The following summarizes the chief disabilities which the studies of the committee revealed:

1. The Association has lacked financial resources to encompass the various enterprises which it has attempted to carry on.
2. Enterprises of importance have suffered because of a scattering of effort, time and money along too many lines.
3. Continuity in policy and in administration has frequently been lacking.
4. The executive as well as the administrative functions of the officers have not been clearly defined—as a result uncertainty and variation in performance have followed.
5. Clearly defined financial policies have been lacking. The financial methods of the Association have in important respects lacked effective organization.
6. In general, the value of the Association's service has been seriously impaired by various defects revealed by the committee's study. The objectives of the Association could not for these reasons be adequately achieved, and substantial financial and personal support is not likely to be secured until appropriate measures to remedy these deficiencies have been instituted.

On the basis of these findings certain proposals as to policies, organization, major activities and finances have been formulated. It has not been possible

to circularize all of our membership to acquaint them with these findings and proposals and to profit by their experience and suggestions, because of the costs involved and the necessity for prompt action. The Executive Board was therefore constrained to content itself with the counsel of a necessarily limited number of Fellows with whom contact could more readily be made, before publishing these proposals.

In offering the suggested changes, the Executive Board is mindful of the many excellent features in our present organization which it has sought to retain. It has also been studious to avoid modifications except where they would be likely to serve valuable purposes. Within the limits of space here available it is impossible to set forth the many considerations and reasons that have led to the conclusions upon which these changes are based.

In general the primary aim in these recommendations is to establish continuity in the government of the Association and to strengthen the executive and administrative services. In addition, such revisions have been designed to add to our existing governmental machinery the agencies and the personnel which could best formulate and execute comprehensive and sustained activities.

To effect these purposes, the Executive Board proposes certain necessary changes in our Constitution and By-laws which are here grouped under 4 headings:

1. General administrative organization
2. Major objectives and machinery for their development
3. Executive organization
4. Changes in Section organization

I. GENERAL ADMINISTRATIVE ORGANIZATION

A. *Officers*—To remedy the lack of continuity in administration, it is proposed that the Association elect annually a President-elect, who shall be a member of the Executive Board and in intimate contact with the affairs of the Association. In place of the Executive Secretary, it is proposed that a Fellow shall be elected to serve as Secretary of the Association with such clerical aid and assistance from our employed staff as he may require. The duties of the various elected officers are to be more specifically defined in the Constitution and By-laws in order to fix responsibility and to mark the bounds of authority.

B. *The Governing Council*—The functions of the Governing Council are to be as follows:

1. To establish policies for the Association and for the guidance of the Executive Board and the officers.
2. To establish Sections of the Association; to combine or discontinue them when necessary; to maintain coördination among them; and to formulate general rules governing the policies of the Sections.
3. To submit to the vote of the Association all resolutions which have received the approval of the Governing Council.
4. To elect and establish qualifications for Affiliated Societies, Fellows, Honorary Fellows and Members as provided in the By-laws.
5. To elect the Executive Board and the officers of the Association.
6. To receive from the Executive Board at its first session, at the time and place of the Annual Meeting of the Association, a definitely formulated statement of a program of major activities proposed for the ensuing year. At the Annual Meeting of the Association the Governing Council shall determine in general outline the allocation of Association moneys in the budget for the ensuing year. It shall require a report from the Chairman of the Executive Board in which the work, the accomplishments and the financial status of the Association during the year preceding such Annual Meeting shall be reviewed.
7. To publish after each of its meetings an abstract of the minutes of such meetings.

The purpose of the requirement that the Governing Council publish minutes in abstract form of all of its meetings is to acquaint the membership at large with its activities.

Inasmuch as it is desirable to provide

for as democratic and as equitably apportioned representation on the Governing Council as possible, it is recommended that the members at large to be elected each year to the Governing Council shall be nominated by a Nominating Committee which shall consist of one Fellow elected by each section, and an eleventh one designated by the Executive Board, all of whom shall be designated at the preceding Annual Meeting. It should be clearly noted in this connection that this recommendation does not abolish the present provision in the Constitution and By-laws making it possible for any twenty-five Fellows to make nominations for membership on the Governing Council.

In view of the fact that membership on the Governing Council should have great significance, the Executive Board decided to hold a referendum to ascertain from the Fellows of the Association the conditions under which an Affiliated Society may be privileged to be represented on the Governing Council. It has been contended that those Affiliated Societies that are well organized and a source of strength and support to the American Public Health Association should logically be thus represented. On the other hand, certain health associations which may now or in the future be affiliated may lack such elements of strength, and therefore the question arises whether they should exercise voting power. The referendum will in due time be held and the question will be more adequately presented.

C. *The Executive Board*—The Executive Board shall be composed of four Fellows to be elected by the Governing Council for terms of five years each. In the beginning, one shall be elected for a term of one year, one for two years, one for three years, and one for four years, and thereafter one shall go out of office each year. These elected members shall be past or present members of the Governing Council. The Executive Board shall in addition comprise the President, the President-elect, the retiring President, the Treasurer, and the Secretary, as members ex-officio with full voting power.

The Executive Board shall elect its own chairman, and he shall hold office for not more than three years, and not be reëlected after such tenure of office until one year has elapsed. He shall have authority to appoint all committees of the Association, subject to approval by the Executive Board. He shall be a member of the Governing Council. These proposals, also, are designed to fix responsibility more definitely and to centralize administrative control.

The proposed duties of the Executive Board shall be as follows:

1. To direct the administrative work of the Association.
2. To act as Trustee of the Association's properties.
3. To plan methods for the procurement of funds.
4. To recommend budgets for the Association's work.
5. To conform to the policies of the Governing Council in the conduct of its work.
6. To approve the appointment of committees by its chairman.
7. To transmit a report of its proceedings and transactions to the Governing Council at least thirty days before each Annual Meeting.
8. To ratify the appointments and changes in the employed staff of the Association.

II. MAJOR OBJECTIVES AND MACHINERY FOR THEIR DEVELOPMENT

In order to focus clearly upon the major objectives of the Association and to create machinery for their more comprehensive development, it is recommended that the fourscore existing committees be discontinued. Where definite commitments have already been made, however, with respect to special projects, the Executive Board is to carry out such commitments in a way that will best harmonize with the general scheme of organization herein proposed.

The Executive Board is reasonably

confident that all of the major objectives of the Association can be effectively centralized in four standing committees. It feels convinced that all committee activities will find a logical and effective place under one of these four standing committees. Any special committees that may be required to carry on important services of the Association can be constituted as subcommittees of one of the standing committees. The functions and composition of these four standing committees are briefly stated in the following:

A. *Committee on Administrative Practice*—The size, the composition and the employed personnel of this committee are to remain unchanged, so as to carry out commitments already made.

B. *Committee on Meetings and Publications*—The scientific transactions at our Annual Meetings form the largest and most substantial contribution to our publications. Furthermore, the major activities of the Association and its members would profit most if the plans and the conduct of the Annual Meeting were in the hands of a standing committee which would correlate the program of the Annual Meeting with the publication work of the Association. To this end a committee to be known as the Committee on Meetings and Publications shall be appointed to consist of five members serving for terms of five years each; in the beginning one shall go out of office at the end of one year, one at the end of two years, one at the end of three years, and one at the end of four years, and thereafter one shall go out of office each year. After serving for two consecutive terms a member shall not be eligible for reëlection until one year has elapsed.

C. *Committee on Research and Standards*—The Committee on Research and Standards should be responsible for carrying out research in relation to the development of standards in important branches of public health work and coördinating such research and standardization in a manner that will not conflict with the functions of the Committee on Administrative Practice. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council. This committee shall also be charged with the duty of reviewing from time to time standards already established, so that they will be made to harmonize with current theory and practice. This committee shall consist of fifteen members representative of the various points of view in public health practice, appointed for three year terms, one-third the total membership expiring annually. After serving for two consecutive terms a member shall not be eligible for reëlection until one year has elapsed.

D. *Committee on Fellowship and Membership*—This committee shall pass upon the eligibility of Fellows and Members; it shall carry on membership promotion and recommend action to the Executive Board to suspend or drop Fellows and members for nonpayment of dues. The committee should consist of ten Fellows, one to be chosen by each section and to serve for a term of two years. In the beginning, the Executive Board shall designate the five members who shall serve one year. An eleventh member shall be designated by the Executive Board to serve for two years. After serving for two consecutive terms a member shall not be eligible for reëlection until one year has elapsed.

The programs and policies and special activities formulated and directed by the above named standing committees should be carried out by salaried secretaries employed for the purpose.

The Executive Board cannot too emphatically record its judgment based on the studies that have been made, that no project should be included in the program of activities for a given year unless such project has been formally approved by the Governing Council. It also seeks to establish it as a principle of action that the Executive Board shall prepare and submit a tentative program of activities and a tentative budget for the next ensuing year, and that such program of activities and budget shall be acted upon by the Governing Council at the Annual Meeting, at which time the latter will determine in general outline the allocation of Association moneys in the budget for the ensuing year. A further principle of action which the Executive Board would recommend to future Executive Boards and Governing Councils would be to withhold from submitting or approving a program for which financial support is not reasonably assured.

III. EXECUTIVE ORGANIZATION

It is recommended that the title of the Executive Secretary shall be changed to Executive Director, or to some other designation which will more accurately indicate his actual position and duties in the Association.

As a result of these studies certain changes have already been effected in the auditing service, and in relation to office management. The more substantial changes that have been found necessary are under consideration and will be referred to the succeeding Executive Board for final decision.

The management of the finances and the financial policy of the Association were made the subject of very careful study. Changes have been inaugurated and will be further developed to bring our financial methods into harmony with current business practice.

IV. CHANGES IN SECTION ORGANIZATION

To overcome certain disabilities in the organization and functions of the section councils and better to define their duties and responsibilities, it is recommended that section councils shall each consist of five members elected by the section for terms of five years each; in the beginning one shall serve for one year, one for two years, one for three years and one for four years, and thereafter one shall go out of office each year. This will assure continuity in planning the activities and in shaping the policies of the respective sections.

In view of the fact that section constitutions and by-laws have not been generally adopted, nor in effect where adopted, it is deemed necessary in the best interests of simple and effective organization to eliminate section constitutions and by-laws.

It is recommended that each section council shall elect its own council chairman and such other council officers as it deems necessary, and the duties of the section council are as follows:

1. To recommend papers, and to make general recommendations in relation to the Annual Meeting program.
2. To advise on section membership.
3. To advise on section policies.
4. To submit annually to the Governing Council through the Executive Board a report of the transactions of the section.
5. To report annually to the Governing Council through the Executive Board on the plans, scope and policy of the section during the succeeding year.
6. To formulate rules of procedure for the section.
7. To approve and transmit to the Governing Council resolutions originating in the section.
8. To advise on the publication of papers and reports presented at the section meetings.
9. To advise with respect to the appointment of technical committees, sub-committees or section representatives on special committees of the Association.

It is understood that the election of section officers, namely chairman, vice-chairman, and secretary of the section, shall go on as at present.

It is recommended that the Constitution and By-laws be amended to require that every Fellow or Member shall consummate affiliation with some section in the Association within twelve months after election to such Fellowship or Membership. A Fellow or Member failing so to affiliate shall be placed in an appropriate section by the Executive Board.

The Executive Board submits the results of its labors and deliberations in the hope that those of our Fellows and Members who have constructive suggestions to offer will do so at once, and that all will coöperate in giving effect to the substantial features of the proposed plan of reorganization.

PROPOSED CONSTITUTIONAL AMENDMENTS

In accordance with the provision of the Constitution, notice is hereby given of the following proposed amendments to the Constitution, which, if approved by the Governing Council, will be voted on at the Minneapolis meeting.

ARTICLE III, *Section A,* Paragraph 4.

Now reads:

A representative to be appointed by each affiliated society to serve for one year. Such representative shall be at the time of his appointment a Fellow of the American Public Health Association.

To be amended as follows:

Representatives to be appointed by Affiliated Societies as provided for in the By-laws. Such representatives shall be Fellows of the American Public Health Association.

ARTICLE III, *Section E,* Paragraph 4.

Now reads:

To elect Affiliated Societies, Fellows and Honorary Fellows as provided in the By-laws.

To be amended as follows:

To elect and establish qualifications for Affiliated Societies, Fellows and Honorary Fellows as provided in the By-laws.

ARTICLE III, *Section E,* Paragraph 6.

Now reads:

To receive from the President, on behalf of the Executive Board, a report of the meetings, policies and work of the Executive Board; a report from the Executive Secretary concerning the administrative work of the year; and a report from the Treasurer concerning the finances of the Association.

To be amended as follows:

To receive from the Executive Board at its first session, at the time and place of the Annual Meeting of the Association, a definitely formulated statement of a program of the major activities proposed for the ensuing year. At the Annual Meeting of the Association the Governing Council shall determine in general outline the allocation of Association moneys in the budget for the ensuing year. It shall require a report from the Chairman of the Executive Board in which the work, the accomplishments and the financial status of the Association during the year preceding such Annual Meeting shall be reviewed.

Add:

7. To publish after each of its meetings an abstract of the minutes of such meetings.

ARTICLE III, *Section G.*

Omit the word "Executive."

ARTICLE IV.

Now reads:

The officers of this Association shall be a President, three Vice-Presidents, an Executive Secretary and a Treasurer. The officers, with the exception of the Executive Secretary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. Officers shall serve from the close of the Annual Meeting when elected, until the close of the next Annual Meeting, and until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained. The Executive Secretary shall be elected by and serve at the pleasure of the Executive Board.

To be amended as follows:

The officers of this Association shall be a President, a President-elect, three Vice-Presidents, a Secretary, a Treasurer and the Chairman of the Executive Board. The officers, with the exception of the Chairman of the Executive Board, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. Officers shall serve from the close of the Annual Meeting when elected, until the close of the next Annual Meeting, and until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained. The Chairman of the Executive Board shall be elected by the Executive Board.

ARTICLE V.

Substitute word "Fellows" for "Members."

APPLICANTS FOR FELLOWSHIP

LABORATORY SECTION: George F. Reddish, Ph.D., Washington, D. C.

HEALTH OFFICERS SECTION: Henry L. Akridge, M.D., Brunswick, Ga.; George H. Bigelow, M.D., Boston, Mass.; William C. Blake, M.D., Princeton, N. J.; Lester Van D. Chandler, Hackensack, N. J.; Warren F. Draper, M.D., Washington, D. C.; Charles H. Kibbey, M.D., Fairfield, Ala.; Burton K. Kilbourne, M.D., Fargo, N. D.; George Parrish, M.D., Los Angeles, Calif.; Charles W. Strowger, M.D., New Orleans, La.

VITAL STATISTICS SECTION: John Collinson, M.D., Baltimore, Md.; Willard C. Smith, Washington, D. C.

PUBLIC HEALTH ENGINEERING SECTION: Victor M. Ehlers, Austin, Tex.; A. H. Wieters, Des Moines, Ia.

INDUSTRIAL HYGIENE SECTION: Samuel C. Beach, M.D., Chicago, Ill.; James A. Britton, M.D., Chicago, Ill.; Bernard S. Coleman, Jersey City, N. J.; Henry H. Kessler, M.D., Newark, N. J.; Daniel J. Kindel, M.D., Fairmont, W. Va.; Clarence O. Sappington, M.D., Chicago, Ill.; Harold W. Stevens, M.D., Newtonville, Mass.

FOOD, DRUGS AND NUTRITION SECTION: Carl D. Geidel, Le Sueur, Minn.; Frederic W. Howe, Brooklyn, N. Y.; David B. Jones, Ph.D., Washington, D. C.; William B. Palmer, Orange, N. J.

CHILD HYGIENE SECTION: Helen Albano, Dr.P.H., Nashville, Tenn.; Maud A. Brown, Ph.B., New York, N. Y.; Reba F. Harris, Greensboro, N. C.; Harriet L. Hartley, M.D., Philadelphia, Pa.; Charles N. Johnson, D.D.S., Chicago, Ill.; Guy S. Millberry, D.D.S., San Francisco, Calif.; Clealand A. Sargent, M.D., Dover, Del.

PUBLIC HEALTH EDUCATION SECTION: Charles F. Glueck, Boston, Mass.; George F. Granger, Detroit, Mich.; Fred J. Wampler, M.D., Richmond, Va.

EPIDEMIOLOGY SECTION: Frank E. Coughlin, M.D., Harrisburg, Pa.; Edward H. Marsh, M.D., Albany, N. Y.; Clarence L. Scamman, M.D., Newtonville, Mass.; Herman F. Senftner, M.D., Albany, N. Y.

UNAFFILIATED: Adelaide Brown, San Francisco, Calif.; John C. Burkle, M.D., Lafayette, Ind.; Archibald S. Dean, M.D., Jamestown, N. Y.; George D. Heath, M.D., Bloomington, Ill.; John A. Kingsbury, New York, N. Y.

NEW MEMBERS

Angel de la Garza Brito, M.D., Mexico City, Mex., General Supervisor, Public Health Service

George H. Conn, D.V.M., B.S., Freeport, Ill., Veterinarian

Herbert A. Dirckze, Paiyagala, Ceylon, Medical Officer of Health, Kalutara Totamune Health Unit (Assoc.)

Winnifred G. Edgerton, R.N., Dubuque, Ia., School Nurse, Newton, Ia.

J. Frank Field, Caruthersville, Mo., Sanitary Inspector

Mildred W. Gardiner, M.D., B.A., Middletown, O., Assistant Surgeon, American Rolling Mill Co.

Abraham A. Gonzalez, M.D., Mexico City, Mex., Assistant General Surgeon

Geneva F. Hoilien, R.N., Detroit, Mich., Assistant Director, Detroit Visiting Nurse Association

Lafayette Isley, M.D., Excelsior Springs, Mo., City Health Officer

Dr. Bruno LaHaye, Nicolet, P. Q., Health Officer

Christina R. Love, R.N., Philadelphia, Pa., Pennsylvania Department of Health

John J. McNamara, M.D., A.B., Lowell, Mass., Director of School Hygiene

Josephine Marchesseau, R.N., Elkhart, Ind., Child Welfare Supervisor

Ellen O. Miller, Wellesley Hills, Mass., Clerk-Technician, Board of Health

Lucy M. Osler, Punxsutawney, Pa., State Nurse

George Shabo, D.C., Ph.C., B.S., Los Angeles, Calif. (Assoc.)

Solomon L. Skvirsky, M.D., Holyoke, Mass., Secretary, Board of Health

George L. Thompson, M.D., Wickliffe, Ky., Health Officer

Alexander R. Volk, Jersey City, N. J. (Assoc.)

William G. Wheatley, M.D., Azusa, Calif, Deputy Health Officer

Harriet F. Young, R.N., B.S., Wilkes-Barre, Pa., Executive Director, Visiting Nurse Association

DECEASED MEMBERS

Charles W. Bartlett, M.D., Tampa, Fla., Elected Member 1928

William J. Fleming, M.D., Troy, N. Y., Elected Member 1928

Lockhart Nelson, Hillsboro, O., Elected Member 1928

Chandler P. Robbins, M.D., Columbus, O., Elected Member 1925

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Reporting of Venereal Disease in Michigan—[In keeping with our policy of endeavoring to make this section a forum for Health Administrators, Don M. Griswold, M.D., D.P.H., Deputy Commissioner of the Michigan State Health Department, has favored us with a statement regarding the policy of his department with respect to the reporting of venereal diseases. This statement was written in response to one of the numerous inquiries received at Dr. Griswold's office but should prove of interest to all readers of the Journal.—Editor.]

All positive laboratory reports are presented not only to the physician but to our Bureau of Records and Statistics. These are checked against reported cases. If the case is not reported in a reasonable length of time, it is made a subject for query.

We keep in close touch with clinics, hospital services and other organizations caring for these patients. If we can find occasion to call their attention at least once a month to the fact that they are amiss in reporting, it serves to keep them alert.

Our reporting system:

(a) Our blanks require cases to be reported directly to the Michigan Department of Health, giving the name, street, and number. We have ceased emphasizing the venereal aspects of the diseases and are emphasizing their contagiousness and the fact that the greatest thing that a public health agency can do is to reduce the time of infectiousness. By doing away with many of the war-time procedures which only indirectly bear on the problem, and by concentrating on the parts of the program that are effective and have a direct bearing on the people, we are making progress. We believe that cases should be reported by name and address. I have heard health officers argue for hours that the number of the patient is as much good as the name. I can only say for these men that they are piling up administrative difficulties for themselves and making it much harder to accomplish the few simple things that we know are effective. I do not believe it is good administrative policy to make work harder, and we always strive to make it easier. Our cases are, therefore, reported by name and address.

(b) Is the question "Is this patient now under treatment with you?" important?

If this question is answered "yes," we feel that all that can be done is being done to make this patient non-infectious at the earliest possible moment. If this patient does not continue treatment with the physician until he is non-infectious, this fact must be reported to the Michigan Department of Health. When such report is received and an inspector calls on the individual and requires that he go under treatment at once, usually he claims that he had merely changed his physician. We cannot designate the doctor, but the patient must be under medical care if he is to be free from the houndings of our inspector.

If the above question is answered "no," the inspector calls on the individual and takes him to a physician where he will receive adequate treatment.

(c) The source of infection is also required to be given by name and address. If the source is under treatment with the same doctor as the orig-

inal case, he usually designates this fact. We then have an inspector call on this person and explain that he has not been following the doctor's advice with regard to preventing the spread of infection to others and that this constitutes a penitentiary offense in this state. If we are satisfied that this advice is sufficient it is left as a warning. If it appears that it is not sufficient, we take him to court and send him to a penal institution where he will receive proper attention.

If the source is not under treatment with the doctor who reports the original case, we go over our records to see if the case was reported by some other doctor. If it is found to have been reported, we proceed as above. If it is found not to have been reported, the inspector calls on the person to inquire into the facts of the case. The state law gives us the right to make examinations of persons that are "reasonably suspected" of having a venereal disease. Our position is that if a report reaches us as described above, that constitutes sufficient grounds to be "reasonably suspected."

If after this examination the physician will certify to the fact that the patient is non-infectious, we can go no further. If he finds laboratory or clinical evidence of the case being infectious, we require the person to place himself under treatment at once.

You can see from this that our efforts are directed toward placing venereally infected persons under treatment. This is the best way, of which we have knowledge, to render them non-infectious at the earliest possible moment. This wins for us the approval of the medical profession, who give their coöperation in the matter of case reporting. It frequently happens that a physician will report a case of venereal disease, and by using his ingenuity, will get the name and address of the source. Our inspector will call on the source and, if clinical examination is indicated, will bring the source of infection to the doctor's office for examination. Thus, the doctor has tangible evidence that we are coöperating with him. We can be of service to him, and he can be of service to us. To bring to the doctor the case needing treatment is far better pay for case reporting than would be the taking of 10 or 25 cents out of the state treasury for such report.

Use of Tabulator in Syracuse—[I. F. Thompson, M.D., has been good enough to send the Editor a statement concerning the use of the tabulator employed by him and Dr. Ruhland. This tabulator is a simple device which gives a ready method of finding the total amount of work performed.—Editor.]

Record forms have been planned for the Visiting Nurse Association and the School Health Service of Syracuse and both are using the tabulator to their entire satisfaction. The usual records can be planned for the use of such an aid. The principle is that of the "visible index." In this instance, the total of the day's work performed appears as the "visible index." The routine of operation is as follows:

In the Nursing Division of the Health Department and Visiting Nurse Association the daily reports are made out by the nurse and then given to the station supervisor for her information and checking. After the report is corrected, it is filed under the nurse's name. Shortly after the end of the month, when all the daily reports have been received, all the reports of an individual nurse for the month are placed in the tabulator and the columns added. A blank daily report is placed at the bottom of the tabulator on which is entered the totals of the nurses' work for the month. The tabulator should have as many leaves as there are working days in the month. After the totals for each nurse have been made, then

the sheets bearing the totals are placed in the tabulator and the total activities of the nursing staff are secured in one addition. These totals could be made at the end of each week, if desired.

What is saved by this method of procedure? In making up a bureau report under ordinary methods it is necessary to transcribe to a nurse's monthly report her activities for each day. At the end of the month, the monthly summary is made for each nurse. It is then necessary to transcribe each monthly summary to a summary for the department, then add, to obtain the total for the entire bureau. By means of the tabulator, there is no transcribing. The original figures are added to obtain the total for the individual nurse and that total is added to obtain the total for the bureau.

We believe it is a labor saver. Reports from the Visiting Nurse Association show that while they have doubled their staff and have more than doubled their work, the one clerk is able to get out her monthly report in less time than before they adopted this method.

LABORATORY

C. C. YOUNG

THE DETERIORATION OF IODIZED SALT

M. STARR NICHOLS, PH. D., FELLOW A. P. H. A.

Chemist, State Laboratory of Hygiene, University of Wisconsin, Madison, Wis.

SINCE iodized salt has been advocated and recommended quite generally by health officials and health boards as a means of supplying the deficiency of that element in the diet, it was thought advisable to ascertain if the quantity of iodide added remained under ordinary conditions of handling and sale of the article.

The samples were purchased in the open market. There were no means of determining how long the iodide had been mixed with the salt but a statement was given by the wholesaler or retailer of his opinion as to the age of the salt. The answers showed the samples to be from 1 to 4 months old at the time of purchase. Analyses were not made until 6 months after collection, so that the uncertainty as to age would be somewhat compensated for.

Twenty-six months from the time of the first analyses the iodide was again determined. If we consider the average age as 9 months at the time of the first analyses, and 35 months at the time of the second, we should be near the truth for estimation of deterioration.

Determination of the quantity of iodide present was carried out by the method of Kelly and Husband,[1] which is a slight modification of that of Kendall.[2] In applying this method it was found satisfactory to omit the first part of the procedure, which was intended for use when organic matter was present.

METHOD

Ten grams of the salt were placed in a Kjeldahl flask and 400 c.c. of water added. After solution, 3 c.c. of syrupy phosphoric acid and 6 drops of bromine were added. The flask was agitated to dissolve enough of the bromine so that the solution took on a deep yellow to brownish color. This treatment oxi-

TABLE I

AMOUNT OF IODIDE IN IODIZED TABLE SALT

Sample Designation	Amount of Sodium or Potassium Iodide Claimed Per Cent	Amount Found After 9 Months Per Cent	Loss First Period Per Cent	Amount Found After 35 Months Per Cent	Loss Second Period Per Cent
A	0.05	0.034	32.	0.029	15.
B	0.02	0.017	15.	0.016	6.
C	0.02	0.013	35.	0.015	—
D	0.02	0.026	—	0.016	38.
E	0.023	0.0105	54.	0.010	4.
F	0.02	0.008	60.	0.008	0
G	0.02	0.011	45.	0.0077	31.
EE *	0.023	0.015	35.	0.015	0
H	0.0222	0.017	23.	0.0008	95.
EEE	0.023	0.018	22.	0.015	16.
AA	0.05	0.042	8.	0.039	7.
FF	0.02	0.029	—	0.029	0

K	0.02	0.0012	94.	0.00	100.

* Samples with more than one letter indicate same brand purchased at different localities.

dizes the iodide present to iodate. After a few moments the flask was placed on the Kjeldahl burner, connected with the gas exhaust, and the solution boiled until there was no noticeable trace of bromine left. This usually required the loss of approximately 100 c.c. of water. To make sure that all the bromine had been expelled, a pinch of salicylic acid was added to the flask to offer combination to any trace of bromine which might remain. The flask containing the iodate in solution was cooled to room temperature, 0.25 to 0.5 gm. of potassium iodide dissolved in 5 c.c. of water was added and the resulting iodine titrated with N/200 sodium thiosulfate solution made freshly from a N/40 carefully standardized solution. The end point was accentuated by the usual starch indicator solution.

The iodide present in the salt was then calculated by the following relation:

$$\frac{\text{c.c. thiosulfate used} \times .0009301}{6} = \text{Potassium Iodide present in sample taken}$$

This method permits the estimation of minute quantities of iodides or iodine because 6 times as much iodine is titrated as was originally present in the substance analyzed.

To make sure that the large amount of sodium chloride would not interfere with estimation of the small amount of iodide, salt containing a known amount of iodide was analyzed. Four duplicate determinations were made, adding 0.005 gm. of potassium iodide to 10 gm. of iodide free salt. These gave 0.00502, 0.00503, 0.00502 and 0.005 gm. respectively.

DISCUSSION

The results show considerable loss during the first period of storage and a corresponding decrease thereafter. These first losses may, however, be only apparent as no attempt was made to check the accuracy of the manufacturer's statement of iodide content. Johnson and Herrington [3] consider that

sunlight and heat accelerate the deterioration, and individual samples before collection may have been kept under unlike conditions. Von Fellenberg [4] states that potassium carbonate does not affect the loss. After collection our samples were kept on the chemical shelves of the laboratory away from heat and sunlight and at room temperature. After 35 months' storage it will be noted that samples H and K had lost practically all their iodide.

Manufacturers of C, G and K stated that 1 per cent of calcium phosphate had been added. Samples A, E, H and AA contained 1 per cent calcium phosphate + 1 per cent sodium bicarbonate, and with the exception of sample H these samples did not deteriorate appreciably.

Other antihardeners used were magnesium and calcium carbonates. No definite relationship was established between these added materials and the keeping qualities.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Pulmonary Tuberculosis among the Insured—An analysis was made of 1,000 deaths from pulmonary tuberculosis among insured policy holders. The material for this study was taken from the files of the Pacific Mutual Life Insurance Company of California. The data compiled represent the findings in the medical examiners' reports at the time insurance was issued, the Disability Claim file, and the Death Record. A 15-year period of time is covered extending from 1913 to 1928. The average time that elapsed from the date of application to the beginning of illness was 4 years. The disability covered an average period of 2 years and 3 months. The average life policy was between 7 and 8 years. For one-third of the policies it was 5 years or less; for one-third 5 to 10 years; and for one-third over 10 years. There was an average age of 32 years at the time of application, and at the beginning of illness the age was approximately 35 years. The average age of death was between 38 and 40 years. Underweight occurred among 761 of the cases. Two hundred were 5 per cent underweight; 246 were 10 per cent underweight; and 127 were 20 per cent or more underweight. Two hundred and thirty-nine of the cases were overweight. There was a family history of tuberculosis in 7.4 per cent of the underweights and 8.7 per cent of the overweights. Low blood pressure was found in 3.2 per cent of the underweights and 2.1 per cent of the overweights. A history of influenza was found in 11 per cent of the underweights and 5.9 per cent of the overweights, and a history of common colds was found in 5.4 per cent of the underweights and 6.2 per cent of the overweights. A history of lymph-node enlargement was found in only 2 cases.

A study of the data suggests that

underweight is the factor which most clearly indicates a bad prognosis. A family history of tuberculosis associated with underweight is of less importance than is generally assumed. This conclusion is drawn from the fact that there was a positive family history in just as high a percentage of overweights as in underweights. A personal history of upper respiratory disease is a common finding, and of importance especially if the condition is chronic or recurrent. Low blood pressure is not of vital prognostic significance.—L. H. Lee. An Analysis of 1,000 Deaths from Pulmonary Tuberculosis among Insured Policyholders, *Am. Rev. Tuberc.*, 19: 412 (Apr.), 1929.

Diphtheria Mortality in Large Cities of the United States in 1928—A survey of diphtheria deaths in 81 cities of more than 100,000 population shows that 11 cities had mortality rates of less than 2.0 per 100,000 population in 1928. Two cities, Grand Rapids and Tacoma, had no diphtheria deaths during 1928. Tacoma was among the 10 cities with highest diphtheria deaths in 1925 and 1926, and Grand Rapids among the 10 cities with highest 1920–1923 averages. Of the other 11 cities, Des Moines had a rate of 0.6, Erie a rate of 0.7, Seattle a rate of 1.0 and Utica a rate of 1.0. Rates of 10.0 and over occurred in 21 cities in 1928, as against 31 in 1927. In 1928 there was only 1 city, Newark, which had a diphtheria death rate of 20.0, whereas in 1927 there were 2 such cities. Among the eight geographic divisions, the East North Central group of cities had the highest death rate of 11.3, and the Mountain and Pacific group had the lowest rate of 4.7.

Of the 12 New England cities, the Fall River diphtheria death rate showed a striking decrease from 14.3 in 1927 to 3.0 in 1928, the Lynn rate decreased from 19.1 to 6.6, and the New Bedford rate decreased from 15.6 to 9.0. In the Middle Atlantic group the rate for Utica fell from 22.6 in 1926 and 29.2 in 1927 to 1.0 in 1928. In the South Atlantic cities Jacksonville and Baltimore had decreases from 7.2 to 3.5, and from 11.3 to 7.6, respectively. In the East North Central group the largest increase was shown in Akron, where the 1928 rate was 12.4, as against the 1927 rate of 5.2. Three of the 4 East South Central cities had lower diphtheria death rates in 1928 than in 1927. Nashville was the only city with a rate above 10.0. Five of the 8 cities in the West South Central group showed 1928 rates that were smaller than the 1927 rates. The most conspicuous of the decreases were in Fort Worth and New Orleans where the rates decreased from 15.3 to 5.9, and from 15.1 to 8.6, respectively. In the Mountain and Pacific group, Salt Lake City showed a decrease in the diphtheria death rate from 14.0 in 1927 to 5.1 in 1928, and Tacoma, a decrease from 4.7 in 1927 to 0.0 in 1928.—*J. A. M. A.*, 92: 1759–1762 (May 25), 1929.

Typhoid Fever in Large Cities of the United States in 1928—The seventeenth annual report of the *Journal of the American Medical Association,* concerning typhoid fever in 81 cities, has been published. Nine of the 81 cities concerned in this study had no typhoid deaths during 1928. Of these 9 cities, 4 had similar records once before, and another, Yonkers, 4 times before. Twenty-five of the cities had death rates below 1.0 per 100,000 population, as against 20 in 1927. There were only 4 cities with death rates over 10.0 per 100,000.

Four of the 12 New England cities had no typhoid deaths during 1928. This is the largest number of cities in a single group ever to make such a record. For New Haven and Spring-

field it was the second successive year. The rate of 0.6 for Boston was the lowest ever recorded for that city. Fall River with a death rate of 4.5 had the highest in the New England group for 1928, and showed an increase over the 1927 rate of 2.3. In the Middle Atlantic group there were 2 cities, Elizabeth and Yonkers, with no typhoid deaths. The rate of 0.8 for Philadelphia was the lowest in its history. Atlanta in the South Atlantic group had a death rate below 10.0 for the first time since 1919, when its rate was 9.6. Its 1928 rate was 7.4 as compared with 14.0 in 1927.

In the East North Central group, Chicago lowered the 1927 death rate of 0.7 to 0.5, this being its third successive year with a rate below 1.0. Cleveland and Detroit had rates of 0.6 and 1.0 respectively, as compared with 1.0 and 1.2 for 1927. In the East South Central cities, the reductions in Birmingham and Memphis are especially notable. Birmingham's rate declined from 12.9 in 1927 to 7.2 in 1928, and that of Memphis from 14.5 in 1927 to 11.6 in 1928. Among the West North Central cities Duluth had no typhoid deaths. In the West South Central group, 4 of the 8 cities had lower rates in 1928 than in 1927. Tulsa had a rate of 3.5 in 1928, as against 8.7 in 1927, and San Antonio had a rate of 2.3, as against 5.7 in 1927. Tacoma, which stood at the foot of the Mountain and Pacific cities in 1927, and next to the foot in 1926, headed the list in 1928 with a record of no typhoid deaths. This is the second city in the group ever to attain this distinction.—*J. A. M. A.*, 92: 1674–1677 (May 18), 1929.

Measurements of Female Students—This study includes the measurements on 1,022 women entering the University of Minnesota during the school year 1925–1926. The average age was 19.6 years. The average height, 1,617 mm., was above that reported for the women in all American colleges, excepting Stanford, Smith and Vassar. Minnesota women averaged 128 mm. less in height than the men students, but there was no significant difference in variability. The average body weight of the Minnesota women was 54.37 kg., and the coefficient of variation was higher than in the men. In body build the Minnesota women averaged relatively more slender than any other American college group, excepting Oberlin and Nebraska. The average chest expansion was 63.42, as compared with 74 mm. for the men. The vital capacity in the Minnesota women averaged 2,888 c.c., which is above the averages for American college women, excepting Vassar and the groups of nurses. There was a marked sex difference, the vital capacity of the men averaging decidedly higher, even for the same stature and weight.

The correlation of stature with age was insignificant in the group. The normal increase of height with age up to about 20 years fails to occur, probably because those entering at the earlier ages are precocious physically as well as mentally. The correlation coefficient between stature and sitting height was 0.690; that between stature and weight, 0.451; and that between stature and chest girth, 0.254. The correlation between body weight and age in this group was low, there being only a slight tendency for increase of weight with age. The correlations between body build and age, pulse rate, and chest expansion are practically insignificant. The correlation with sitting height was low, while that of 0.672 with chest girth was high. These correlations are similar to those found in the Minnesota men. Vital capacity tends to decrease with age, showing a small negative correlation. The small correlation of 0.120 between vital capacity and chest expansion indicates

that in the women, even more than in the men, chest expansion is a very poor index of vital capacity.—C. M. Jackson. Physical Measurements of the Female Students at the University of Minnesota, with Special Reference to Body Build and Vital Capacity, *Am. J. Phys. Anthrop.*, 12: 363–411 (Jan.–Mar.), 1929.

Prophylaxis of Respiratory Disease with Vaccine—In an industrial plant employing 5,000 men, respiratory diseases caused 34 per cent of all cases of disabling illness, and 35 per cent of all time lost from sickness disability during the past 5 years. Vaccine therapy seemed to offer the most promising means of reducing the respiratory disease incidence. Treatments were given in October and November, 1927, and the results recorded on April 1, 1928. Of 382 cases given preventive vaccine treatment for colds, 68 per cent were benefitted. In two groups of apparently equal susceptibility, 30 per cent of the vaccinated group lost time from respiratory disease as against 49 per cent of the non-vaccinated group. Twelve cases of pneumonia occurred among the non-vaccinated employees and none among the vaccinated group. Sixty per cent of the men with a positive reaction to the vaccine were improved, as against 70 per cent with a negative result. It is probable that the degree of natural immunity governed the extent of the reaction, and that the individuals with a negative reaction had a higher degree of immunity than those with a positive reaction. Cases showing pathological conditions of the nose and throat were 69 per cent improved, as against 68 per cent in the negative cases. The only significant variation was in 55 cases with tonsillar disease which showed an improved rate of 62 per cent. The duration of the immunity produced by an attack of respiratory disease apparently varies over a wide range. A repetition of the maximum dose of vaccine at intervals of 30 to 60 days throughout the season of the prevalence of colds would probably increase the percentage of favorable results.—James M. Adams. *South. M. J.*, 22: 354–356 (Apr.), 1929.

Gall Bladder Operative Mortality—The medical report of 1927 for Garfield Memorial Hospital, Washington, D. C., shows that 169 operations by 23 operators were performed on the biliary tract. Of these operations, 8.8 per cent were fatal. Two of the operators performed 77 of the total operations, with a mortality of 5.1 per cent, as compared with 15 occasional operators whose death rate was 11.5 per cent. For the years 1926 and 1927 the total was 302 operations with a mortality of 6.9 per cent. The mortality rate for the individual operators varied from 1.6 to 28 per cent for the 2 years, giving evidence of some difference in methods used. A study of the charts of the fatal cases suggests that but 3 of the 21 could be classed as plainly unavoidable. In 3 others death may have been due to errors in technic. In 6 cases, death could be attributed definitely to poor judgment, and in 7 there was unquestionably an error in technic. In the last 2 there was error either of judgment, technic, or both.—J. Russell Verbrycke. *South. M. J.*, 22: 452–455 (May), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

CHLORO–PHENOL TASTES AND ODORS IN WATER SUPPLIES OF OHIO RIVER CITIES*

H. W. STREETER

Sanitary Engineer, U. S. Public Health Service, Cincinnati, O.

FOR several years past, and particularly since the war, tastes and odors of such a nature as to identify them with the presence of phenols and allied substances, have been experienced with varying frequencies in water supplies of cities located on the inland waterway systems of the middle-western and eastern portions of the United States. Tastes of a similar nature have appeared in water supplies located in other areas, both of this country and Europe. In no instance, however, has this difficulty been more serious or affected larger groups of population than in the area adjoining and tributary to the upper portion of the Ohio River, which drains a highly industrialized region serving as a center of the coal, steel and allied industries.

A search for the specific causes of the tastes and odors above described revealed the fact that during and since the war period the coke producing industry has been abandoning the use of the older "bee-hive" ovens for burning coke and has been substituting for them modern by-product plants, from which valuable substances are recovered from the gases which formerly went to waste in the atmosphere. The residues from some of these recovery processes, notably those concerned with the manufacture of benzol and ammonia, have been found to contain very considerable amounts of tar, phenols, cresols, creosotes, and similar substances, which, when discharged into sources of water supplies, produce characteristic "medicinal" tastes and odors in them which will be designated hereafter by the single term, "phenols." Although other classes of wastes, notably those derived from producer-gas plants, have been found to contain phenols and like taste producing substances, the relative total amounts of phenols resulting from the operation of coke by-product plants are so much greater than those produced by any other single industry, and their production takes place in such highly concentrated areas, that a large share of the responsibility for the difficulties caused by wastes of this class logically has been attributed to them.

In the upper portion of the Ohio River basin and especially along the Ohio River proper, the situation has been aggravated by the fact that in order to produce bacterially safe effluents for drinking purposes, municipal water purification plants are forced to resort to continuous chlorination of the water in addition to its coagulation, sedimentation and filtration. This condition is

* Discussion of Disposal of Phenol Wastes, by F. Holman Waring, presented before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928. *A. J. P. H.*, 19, 7: 758 (July), 1929; Discussions, 19, 7: 817 (July) and 19, 8: 901 (Aug.), 1929.

due primarily to the large volumes of untreated sewage being discharged into this river system. The addition of chlorine to water containing small amounts of taste producing phenols has been found to intensify the tastes caused by these substances, probably owing to the formation of chloro-phenol and allied compounds which are known to have exceptional taste producing properties.

In March, 1924, a report was prepared by Sanitary Engineer H. R. Crohurst of the U. S. Public Health Service, giving the results of a survey which he made of the water supplies affected by tastes of phenol origin and of the industrial plants producing phenol bearing wastes within the Ohio River basin. In his report, 17 coke by-product plants were listed at that time as discharging wastes of this character into the Ohio and its tributaries. Later reports submitted by the Departments of Health of Pennsylvania, Ohio, West Virginia and Kentucky, at a joint conference held in February, 1926, indicated that about the same number of plants were actively discharging phenol wastes at that time in this river basin.

Systematic records of the appearance of phenol tastes in Ohio River water supplies have been maintained since late in the year 1921 by operators of municipal water purification plants located along the river. These records have been collected by the U. S. Public Health Service from time to time and brought together for comparison. A summary of these records, showing the periods and roughly the relative intensities of phenol tastes observed in Ohio River water supplies, is shown graphically in Figure I, which has been plotted from these records. In this diagram are shown also the approximate locations, with respect to the various water intakes, of coke by-product plants discharging phenol wastes into the Ohio River and its tributaries at intervals during the period 1924 to 1927, inclusive. It will be noted in this connection that of the 17 plants indicated as discharging phenol wastes in 1924, only 4 were given as remaining actual contributors in 1927.* The reduction was brought about as the result of joint efforts by the Ohio River states and manufacturers, following conferences held in 1924, 1925 and 1926. The work thus accomplished has been described so fully † that it is unnecessary here to discuss that phase of the subject.

On referring to Figure I, it will be noted that up to the end of the year 1925, tastes of phenolic origin were present at frequent intervals and, during some periods, almost continuously, in the water supplies of East Liverpool and Steubenville, located, respectively, 43 and 65 miles downstream from Pittsburgh, and in those of Ironton and Portsmouth, located 326 and 355 miles downstream from the same point. At Ashland and Huntington, located short distances upstream from the Ironton-Portsmouth zone of the river but about 240 miles downstream from Steubenville, the recorded tastes were considerably less both in frequency and intensity; likewise at Cincinnati, located about 106 miles downstream from Portsmouth. At Louisville, 130 miles downstream from Cincinnati, no tastes of phenolic origin were recorded until December, 1925, and January, 1926, when a wave of these tastes, of unusual intensity, penetrated throughout the entire river down to this point.

Following the December–January phenol wave of the winter of 1925–1926, a renewed coöperative effort was made by the states of Pennsylvania, Ohio,

---

* In a recent paper, Waring indicates that in the autumn of 1928, this number had been further reduced to 2 plants, located, respectively, at Wierton and Follansbee, W. Va.

† Waring, F. Holman. Results Obtained in Phenolic Wastes Disposal under the Ohio River Basin Interstate Stream Conservation Agreement, *A. J. P. H.*, 19, 7: 758 (July), 1929.

West Virginia and Kentucky to bring about the elimination of phenol bearing wastes from the Ohio River system. The results of this effort, which left only 4 recognized sources of phenol pollution in the Ohio River at the end of the year 1927, were evidenced, as shown in Figure I, by a well marked diminution in the frequency and intensity of phenol tastes in Ohio River water supplies, the only outbreak of serious proportions during this period occurring in December–January of the winter of 1927–1928. The change in the status of such tastes occurring after the winter of 1925–1926 is further indicated by Table I, showing the months of the years 1924 and 1925, as compared with those of 1926 and 1927, in which tastes of phenolic origin were recorded in the water supplies of various Ohio River cities:

TABLE I

	Total Months in Which Tastes Occurred	
City	*1924–25*	*1926–27*
E. Liverpool	11	4
Steubenville	24	3
Huntington	5	2
Ashland	3	3
Ironton	7	3
Portsmouth	13	8
Cincinnati	2	4
Total	65	27

These figures fail to show the true contrast existing in the prevalence of tastes during the two periods indicated, because they do not take account of the greater intermittency and less intensity of such tastes during the later period. If these factors could be weighed properly they probably would show that a reduction amounting to fully 90 or 95 per cent has taken place since the end of 1925.

Aside from the foregoing indications, the conditions illustrated in Figure I are of considerable scientific interest in that they afford fairly definite evidence that the concentration of taste producing phenols in the river has had a marked tendency to become progressively reduced in passing downstream, to a greater extent than can be accounted for by increased dilution or by any other wholly physical influence. The evidence at hand sugggests very strongly, in fact, that a large part of the reduction observed is due to some natural process of purification, similar in its general mode of action to other phenomena commonly associated with the self purification of streams.

The tendency above noted is indicated, broadly: (a) by the sharp reduction in the prevalence of phenol tastes observed in water supplies located at considerable distances downstream from sources of phenol pollution, as compared with their prevalence in supplies located in the more immediate vicinity of such sources of pollution, and (b) by the marked seasonal variations in the relative frequency and intensity of phenol tastes occurring in all of the Ohio River water supplies and especially in those further removed from sources of phenol pollution.

On referring to Figure I, it will be noted that during concurrent periods phenol tastes occurred less frequently at Huntington, Ashland, Cincinnati and Louisville, all of which were located at distances of more than 100 miles downstream from recognized sources of phenol pollution, than at East Liverpool, Steubenville, Ironton and Portsmouth, which were located within short distances of such sources of pollution. The reduction observed has been particularly striking between Steubenville and Huntington, a distance of 242 miles, and between Portsmouth and Cincinnati, a distance of 106 miles. In the latter instance the reduction in the frequency of phenol taste prevalence, amounting to over 80 per cent, occurred in a river stretch in which the total amount of dilution water added to the Ohio, mainly through the Scioto River at Portsmouth,

ordinarily is less than 10 per cent. In the former case, it likewise could be shown that the reduction experienced in the prevalence of phenol tastes was far greater than would be accounted for in terms of added dilution water.

It will be noted in Figure I that although phenol taste producing substances penetrated throughout the Ohio River as far as Cincinnati on several occasions during the winter and early spring, they did not appear during the summer or early autumn at any of the cities removed by any considerable river distance from points at which phenol wastes were discharged into the river. If dilution were a material factor in these variations, their trend would be expected to be exactly the opposite of that actually observed, as the maximum

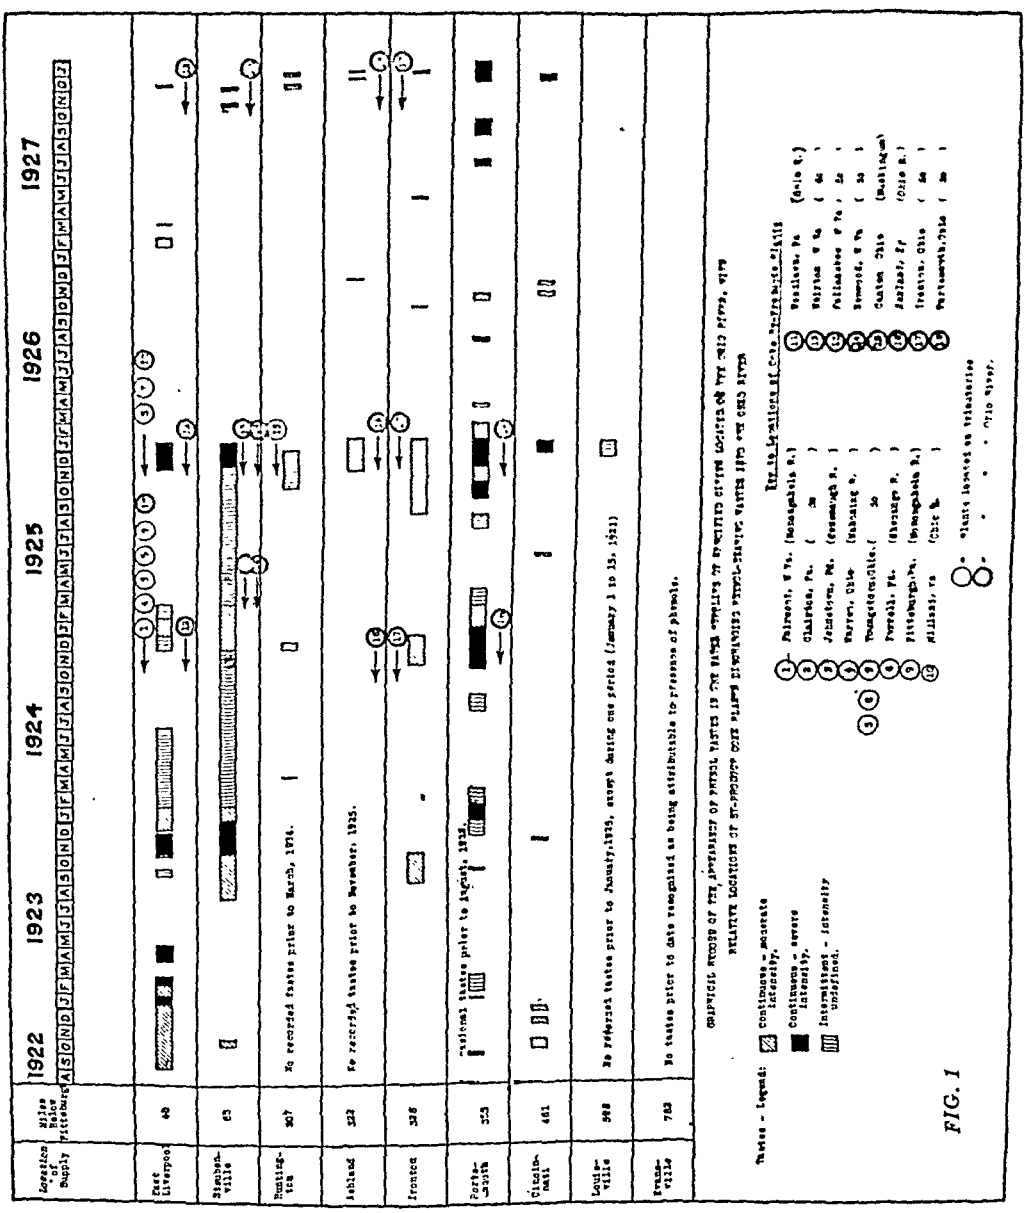

FIG. 1

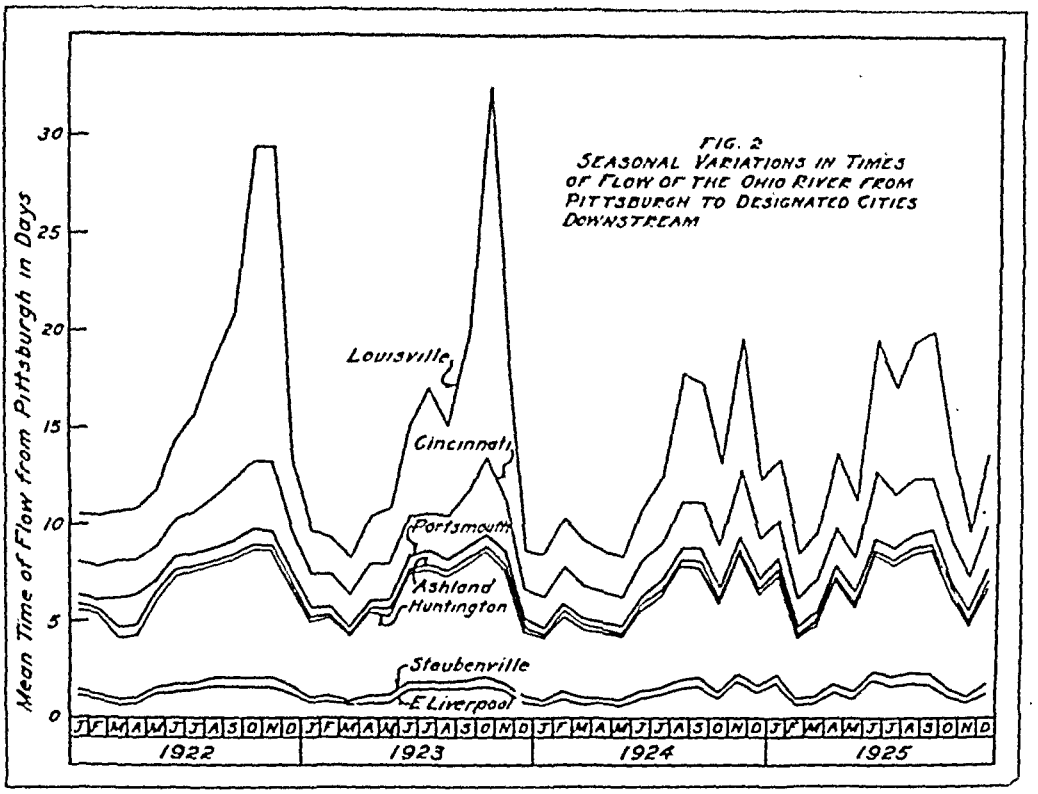
dilution provided by the Ohio River occurs in the winter and early spring, when the river usually reaches its highest discharge.

Although no data are at hand concerning the seasonal trend of production of phenolic wastes by coke by-product plants, it hardly would appear, from the nature of the industry, that such wastes could be produced in sufficiently greater volumes during the winter-spring season, as compared with the summer-autumn period, to account for the wide seasonal variations above noted.



The condition shown in Figure I is entirely consistent, on the other hand, with the view that the changes in phenol tastes prevalence observed in the various Ohio River water supplies, both seasonally and geographically, have resulted largely from some natural process of purification which, though limited in its degree of action, like all other processes of stream self purification, is sufficiently powerful to bring about a marked progressive reduction in the concentration of phenols in stretches of the river relatively undisturbed by pollution of this character. Thus it is noted that the maximum reduction has occurred during the summer and early autumn seasons when the Ohio River usually reaches its lower stages and the effect of longer times of flow, as illustrated in Figure II, is accentuated by that of higher stream temperatures. In general, the periods in which evidences of phenol pollution, as gauged by the appearance of tastes in water supplies, have penetrated to the downstream points far removed from the sources of such pollution, have occurred coincidently with shortened times of flow, as indicated in Figure II, and with relatively low stream temperatures, both of which conditions tend in general to bring about reduced natural purification effects in streams.[1]

In the foregoing connection, reference may be made to recent studies by Mohlman[2] and his associates, which have shown that the oxidation of phenols, which can be accomplished by ordinary biological processes of sewage treatment when phenolic wastes are mixed in proper proportions with sewage, is essentially a biochemical phenomenon, proceeding along definite time-function curves at rates varying closely with the temperature, being greater at higher temperatures, and *vice versa*. As the behavior of phenols in the Ohio River has been consistent, except in degree, with their reactions to artificial processes of oxidation, it would seem quite logical to infer that the progressive reductions thus observed under natural conditions may be due to a process of natural biochemical oxidation similar in its general characteristics to that which proceeds more intensively under artificial conditions.

If the foregoing theory is correct, its lesson is fairly obvious, in so far as its application to problems involving the elimination of sources of phenol pollution of water supplies is concerned. In cases in which water supplies are subject to continuous or frequent pollution by phenols, the important sources of such pollution are more likely to be found in the vicinity of the supply than at any considerable distance.

If, however, they are subject only to occasional pollution, occurring more especially during the colder season or, in streams, coincidently with high river stages, the source of the trouble probably is located at a more distant point.

In undertaking any general program of remedial measures, looking to the relief of phenol pollution of water supplies located along an entire stream, the maximum immediate benefit of such measures probably will be attained by eliminating, first, all sources of phenol pollution located directly on the stream in question or in the lower reaches of tributaries discharging into the main stream above the points at which the

water supplies affected are located. The history of phenol tastes in Ohio River water supplies, both during and following the institution of progressive remedial measures by the bordering states, has afforded an interesting confirmation of the principle stated, as is indicated in Figure I.

The effectiveness with which the pollution of Ohio River water supplies by phenol wastes has been brought under a large measure of control within the comparatively short period of time intervening since the year 1925 constitutes one of the brightest pages in recent sanitary history. Accomplished, as it has been, without any coercive legislation, but through the medium of coöperative effort by the federal and state governments and the industries concerned, it augurs well for the future solution of some of the larger problems of stream pollution now confronting the nation.

Although pollution of the Ohio River system by phenol wastes has not been completely eliminated, as evidenced by occasional "spills" which have occurred during the past year or two, it has been curbed to such an extent as to justify the expectation that in the near future it will cease to be a major problem along this important waterway. A generous measure of credit is due to those whose joint efforts have brought about this fortunate result.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Heating and Ventilation of Liverpool Cathedral—While the first structures including the Lady Chapel, Vestries, etc., of the new Cathedral, begun about 20 years ago, were arranged to be heated by a system of warm air and hot water, the plan for the rest of the immense structure, which, when finished, will be the largest in England and the next in size to St. Peter's at Rome, is to be heated by a new system known as a "warm floor." The system however was used by the Romans as may be seen in the baths at Bath, and the baths at Caracalla at Rome.

Almost the entire floor space consists of a double floor, enclosing a system of shallow ducts. The same air is circulated continually by means of a ventilating fan located in the basement and a hot water coil to raise the temperature to about 80°. Thus the floor becomes an immense radiator, although its temperature is considerably below blood temperature, and for this reason does not feel warm to the feet.

There will be no drying of the air of the Cathedral; heat will be evenly distributed and down draughts prevented; there will be no admixture of the heated air with that of the room space; fresh air for ventilation will be provided otherwise; neither the floors nor the walls will be obstructed by heating devices with their consequent staining effects; and heat will be uniformly distributed also at various levels above the floor, thus providing for "cool heads and warm feet."

The heating system will be put into operation as soon as the basement is finished, so that construction of the building may proceed to completion avoiding the damage which often occurs to joinery and fittings due to weather conditions. While the initial cost is a little greater, the low temperature maintained provides for an unusually economical working. The system is adaptable to houses, churches and halls. —Sir Giles Gilbert Scott, R.A., Architect, G. N. Haden and Sons, Ltd., engineers, Trowbridge, England, 27 pp., ill. (See also *Liverpool Cathedral, Official Handbook* (3d ed.), July, 1924, pp. 85–87.)

Atmospheric Pollution—The annual report for Rochdale (England) for 1927–1928 continues to emphasize the nature of atmospheric pollution, the chief ingredients being tarry matters soluble in carbon bisulphide, the sulphates, chlorine and ammonia. The main source of these tarry matters is the smoke from domestic fires, where the combustion of coal is less complete than in the furnaces of factories. It is a striking fact that rain brings down the soluble impurities of the atmosphere, but has little effect in bringing down the insoluble matter or soot. The explanation of this selective action of the rain probably lies in the fact that the particles of soluble matter containing hygroscopic salts form a nucleus for the rain drops, while the insoluble matter represented by sooty particles of a tarry nature tends to repel water.

While 4 years previously the average monthly deposit was about 63.5 tons per square mile, the deposit for the current year is but 33.24 tons. This decrease is undoubtedly related to the increase in the use of gas and electricity, as a substitute for coal, as a source of

heat and power. In fact, it is calculated that electric power units now used in Rochdale avoid the consumption of roughly 100,000 tons of raw coal per annum by private plants. Further decrease is to be expected from scientific treatment of raw coal to produce a smokeless fuel.—*Med. Off.*, 1089: 248–9 (June 8), 1929.

Health Leaflets for the Printing Trades—Twelve leaflets are enclosed in a folder bearing the above title. One makes an especial appeal to the employer to provide adequate ventilation, sanitary conveniences, seats and vacuum methods of cleaning; another appeals to the employed to coöperate in maintaining proper ventilation, the use of sanitary arrangements, lockers, canteens, the avoidance of the common drinking utensil, and of spitting; another discusses briefly healthy habits but has the rather surprising statements for the prevention of influenza and common colds—"a simple and yet effective preventive is to draw warm water through the nose, morning and evening," and "all cuts and scratches should be kept scrupulously clean and covered with plaster or other dressing."

The leaflet on the prevention of lead poisoning states that within the last 12 years there have occurred 230 cases (presumably in the Printing and Allied Trades of the United Kingdom) of which number 98 were compositors, 55 stereotypers, 20 linotypers, 14 monotypers, 2 electrotypers and 41 otherwise employed. Of this total, 160 cases occurred in ordinary letterpress printing, and 70 in newspaper works. The cases occurred in 185 plants.

The leaflet entitled "Precautions against Consumption" advises that in sedentary occupations the most suitable temperature for a workshop is from 60° to 65° F. One leaflet is devoted to ventilation and health; another to the dangers of bronzing with the claim that bronze dust appears to render workers very susceptible to diseases of the respiratory organs, such as pneumonia and pleurisy. A 4-page leaflet is devoted to good lighting of printing offices; a similar one to the dangers of defective eyesight, this prepared by W. B. Barker, past President of the British Optical Association; and a pamphlet devoted to convalescent homes. In connection with defective eyesight, of 139 employees who were examined by a specialist, 61 were found to require glasses. In another instance, of 134 employees, 86, or 64 per cent, needed glasses or revised prescriptions.—Joint Industrial Council, Printing and Allied Trades of the United Kingdom, 7–10, Old Bailey, London, E.C.4.

Industrial Clinic at McGill University—Dr. Frank G. Pedley, Director, announces that the industrial clinic operated by McGill University in the Montreal General Hospital celebrated its first anniversary in October, 1928. It had a most satisfactory year, having had more than 1,600 people in attendance for examination or treatment. Likewise it stimulated the installation of health service in many industrial plants. It will shortly inaugurate a dental clinic.—*Canad. Pub. Health J.*, XX, 2: 108 (Feb.), 1929.

Tuberculosis in Industry—The Philadelphia Health Council showed that approximately 1.8 per cent of cases of active or suspicious tuberculosis were to be found in small plants, while concerns having well organized medical departments have but 2 to 5 new cases appear per 1,000 employees each year. A definite chest clinic in connection with the medical department is of great value. Arrangements should likewise be made for sanatorium treatment, and fellow workers permitted to visit the sanatorium and, in fact, it is worth while to have one or two employees ac-

company the patient to the sanatorium in order to permit them to spread their impressions when they return.

Unquestionably, arrested cases of tuberculosis should not be put back into strenuous labor nor into any positions where health hazards exist. They should not be permitted to do piecework or any work in which there is an incentive or bonus. With wages and living conditions as they are in the United States at present, the economic status as a cause of tuberculosis has been largely overcome.

In the discussion which followed the above paper, Dr. Sawyer emphasized the necessity of getting all contacts under supervision, especially those in the family. Dr. Garner mentioned a philanthropic industrial plant near New York City manufacturing uniforms and washable goods which employs only recuperatives from tuberculosis.

Dr. L. R. Thompson of the U. S. Public Health Service emphasized that the latest British mortality data point out the unusual importance of tuberculosis as an industrial health problem, the disease being still the greatest cause of death in British industries. Likewise every industry having a high tuberculosis rate has a high death rate from other causes. It is striking to note that those industries which need healthy, strong individuals, such as the steel industry, as a rule, have a low sickness rate and a very low death rate, while less strenuous industries, such as clothing manufacture, have the higher disease rates and death rates.

Dr. Guy L. Kiefer, State Commissioner of Health of Michigan, and a consultant for the telephone company, emphasized that more or less delicate girls appeal to them for employment among whom many are found with a slight rise of temperature and a fast pulse when they apply for work. These are requested to return as often as three subsequent afternoons when, if temperature and pulse readings are not satisfactory, they are refused employment and given advice to consult their physicians or, where they say they have none, they are reported to the Board of Health.—T. Lyle Hazlett, Westinghouse Electric and Manufacturing Co. *Bull. Am. Assoc. Indust. Phys. & Surg.*, III, 1: 2–4 (Mar.), 1929.

Lead—This is Health Practices Pamphlet No. 3 of the new Division of Industrial Health, National Safety Council, 108 East Ohio Street, Chicago, Ill. The pamphlet is a compilation of experience, and should not be confused with official or insurance requirements. The more dangerous lead trades are specified as well as the commoner lead compounds. The toxicity of lead compounds is briefly discussed with a paragraph upon the portals of entry into the body and several upon the fate of lead compounds in the body. A synopsis is given of the diagnosis of lead poisoning, the chief clinical manifestations, the distinction between lead absorption and lead poisoning, and particular attention to the prevention of lead poisoning, both as regards the individual employee and his place of employment. A short bibliography follows. Illustrations show the lead line in the gums, wrist drop, stippled red cells and a proper exhaust system for the protection of workers. There is also a special form for employment and periodic examination of lead workers.

The Prevention of Lead Poisoning—The article discusses proper housing and working conditions in the lead industries, and should be consulted by those interested in the subject.—May R. Mayers, *Indust. Hyg. Bull.*, New York State Dept. of Labor, 124 East 28th Street, New York, N. Y., V, 9: 33–34 (Mar.), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Vitamin A in Avocados—A study of the vitamin A content of avocados was undertaken in view of the probability that their method of growth was favorable to the synthesis of this vitamin. The type used was the Calavo, the highest grade of the fruit, and all determinations were made on the fresh fruit. In the preliminary experiment albino rats in cages with raised screen bottoms were fed 3 different diets, normal diet, vitamin-A-free diet, and avocado diet using 5 gm. of avocado daily. The butter in the normal diet was replaced by lard in the vitamin-A-free diet, and was substituted by 5 gm. of avocado pulp in the avocado diet. Growth curves in this experiment showed the presence of vitamin A. Negative controls developed severe ophthalmia which did not appear in animals on either the normal or avocado ration. In the same experiment on younger rats, 30 days old, weighing about 50 gm., the animals were placed on the Osborne and Mendel control diet. All animals were exposed to the direct rays of the sun 2 days a week. Rats were divided into 4 groups: negative control with no avocado and 3 groups respectively 2.5, 5.0, and 7.5 gm. avocado daily. Ophthalmia appeared in about 5 weeks on the vitamin-A-deficient diet, the test diet starting after the development of ophthalmia. All of the controls were dead at the end of the 3d week, but on the avocado diet maintained good growth for 8 weeks. The growth curves would indicate that the quantity of avocado necessary to maintain good growth for the 8th-week period would be less than the 2.5 daily dose. It is pointed out that the high oil content of this grade of avocado was a significant factor.—Leroy S. Weatherby, J. Ellsworth Youtz, and Ruth V. Watson, *J. Home Econ.*, 21: 360 (May), 1929.

The Action of Irradiated Ergosterol in the Rabbit—Previous investigations chiefly on rats as experimental animals have indicated the toxic effect of excessive doses of irradiated ergosterol. This work was undertaken on rabbits weighing 2.2 to 2.6 kg. and the ergosterol administered orally or intramuscularly, in doses from 0.5 to 10 mg. The ergosterol was dissolved in almond oil, and preliminary tests indicated that the minimal curative dose was 1/20,000 mg. compared to the minimal dose of 8 mg. for cod liver oil.

Autopsies were performed on all animals and chemical determinations were made of calcium in the various tissues. The experiment indicated that doses of irradiated ergosterol greater than 1.0 mg. are decidedly toxic to the rabbit whether the drug is given orally or intramuscularly. Autopsies showed considerable calcium deposits in animals receiving more than 2.0 mg. of ergosterol and none in those receiving 1.0 mg. or less. The deposit was centered in the thoracic aorta, the kidneys and the lungs.

Experiments were undertaken to show the effect of the ergosterol on serum calcium and inorganic phosphate. An increase of serum calcium of from 38 to 49 per cent above normal was produced by doses of 2 to 10 mg. of ergosterol. The smaller doses were less pronounced although the tendency was to some increase. Experiments on some of the

animals with hypercalcemia showed that 10 days after the treatment was discontinued the serum calcium returned to the normal level. The effect on the inorganic phosphorus of the serum was not so definite because of the greater normal variations, but it appears that the administration of sufficiently large doses tends to develop the high inorganic phosphorus level.

An experiment was made to determine the effect of irradiated ergosterol on the tissues. Calcium was estimated in the lungs, kidney, liver, gluteal muscle, and spleen. In the latter organ determinations were averaged for the group. This experiment showed an enormous increase of calcium in the kidneys and lungs, but not in the gluteal muscle and liver, indicating a selective action for the irradiated ergosterol. Doses of 1.0 mg. or less apparently effected no increase of tissue calcium.

A discussion follows as to the relation of hypercalcemia produced by the irradiated ergosterol to the tissue calcium.—Maurice I. Smith and E. Elvove, *Pub. Health Rep.*, 44: 1245 (May 24), 1929.

The Vitamin Content of Honey—The literature from 1918 to 1923 reports investigations of honey to determine vitamin efficacy, all of which showed negative results. In view of the progress in vitamin research, the present experiment was undertaken on honey, testing for vitamins A, B, C and D. Two samples of honey were tested, one an English honey and the other of West Indian origin. There is given a description of the English sample of honey, which when extracted contained 84.95 per cent of dry matter and 0.10 per cent of ash.

Vitamin A was determined in young rats 35–40 gm., in separate cases, on a fat-soluble vitamin-free diet. After vitamin A deficiency was apparent 2 gm. daily dose was administered with a series of negative and positive controls, the latter with 3 drops of cod liver oil. Results showed that 2 gm. of honey contained no appreciable quantity of vitamin A. Vitamins B_1 and B_2 wese estimated on 6 groups of rats with various modifications in the basal diet with the 2 kinds of honey supplemented by autoclaved or dried yeast. All animals received 3 to 5 drops daily of cod liver oil. All the animals except those receiving the dried yeast showed little growth and this was true even when an antineuritic supplement was added. It was concluded, therefore, that both samples of honey were deficient in vitamins B_1 and B_2.

Vitamin C was tested on guinea pigs rendered scorbutic on an appropriate diet. The honey administered was diluted with one-third water, with the initial dose of 3 gm. being gradually increased. Results indicate insufficient antiscorbutic potency in the dose given, averaging around 5 gm. Vitamin D was tested on young rats on a rickets-producing diet low in phosphorus, the animals receiving a daily dose of 2 gm. of each of the different honeys. Negative controls and positive controls with 3 drops of cod liver oil were employed for each honey. Both honeys indicated no appreciable amount of vitamin D.—Edward Hoyle, *J. Biochem.*, 23: 54, 1929.

Effects of High Cereal Diets on the Growth of Infants—Growth and development of 1,200 Japanese and 869 Filipino infants in Hawaii were observed during the first 2 years of life. Diet of both races is high in rice and lacks milk, and infants are breast fed. Three hundred and seventy-nine Hawaiian infants were also examined for skeletal development.

A diet abundant in cereal without milk is compatible with a high birth rate, moderate infant mortality and good growth of the offspring during lactation

for the first 5 months of life, when infants are dependent on breast milk alone, if the mother's diet includes suitable, adequate, supplementary food other than milk.

After 6 months, when the infants have reached the age when additional food is needed, the gain in weight is not so rapid as when cow's milk is used as a supplementary food in the diets of infants. The subtropical location provides sufficient ultra-violet rays in the sunlight to give almost complete protection against rickets, which disease is extremely rare and is mild when it occurs.

Carpal centers develop early in infants in Hawaii. The eruption of deciduous teeth occurs early; earlier for the Japanese than for the Filipino infants. Dental caries was rare during this period of dentition. Disturbances of calcification appear to cause delayed dentition during the second year of life, rather than dental caries.—V. B. Appleton. *Am. J. Dis. Child.*, 37: 284 (Feb.), 1929.

Fatal Septicemia in Man Due to Bacillus (Salmonella) Suipestifer—*B. suipestifer* infections in man are not numerous, but it is not unlikely that they occur frequently unrecognized. Confusion as to the identity of the organism is responsible for a lack of accurate knowledge as to the incidence of infections in the past, and this may account for the failure to find more instances of this infection in man.

Jordan separates the organisms of porcine origin into at least three groups, (1) *B. suipestifer,* (2) *B. Paratyphosus B* (porcine), and (3) *B. typhi suis* or *B. suipestifer voldagsen* or *glasser.* The authors believe that the organism here discussed belongs to the first group of Jordan's classification, namely *B suipestifer.*

The authors indicate that this report shows the necessity of considering *B. suipestifer* as an agent in the production of febrile conditions simulating typhoid fever, especially when organisms of the paratyphoid group are isolated from the blood and all agglutinations with stock strains of *B. typhosus* and *B. Paratyphosus A* and *B* fail.

This article reports a fatal human infection suggesting typhoid fever and due to an organism with the cultural and serological characteristics of *B. suipestifer.* No necropsy of the body was permitted. The patient, an Italian stone mason of 46 years, was admitted to the hospital one week after he showed symptoms. During the course of the disease 3 blood cultures were taken; the first on the 10th day of the disease yielded approximately 8 colonies per c.c., the second on the 16th day of the disease about 75 colonies per c.c. and the third, at death, 225 colonies per c.c. The blood of the patient gave a negative Widal reaction with stock strains of *B. typhosus* and *B. paratyphosus A* and *B.* With the organism isolated from the blood, good agglutination occurred to a titer of 10,000. Later, the patient's serum was found to agglutinate *B. suipestifer* in a dilution of 1:5,000. One c.c. of a 24-hour broth culture of the isolated organism was injected subcutaneously in a rabbit and death resulted in 84 hours. Organisms with cultural reactions similar to that of the patient and which were agglutinated by the patient's serum in a dilution of 1:20,000 were obtained from the heart blood of the rabbit. In other rabbits inoculated with this same organism, death resulted from septicemia and the lesions were marked congestion of the lungs, spleen, liver, kidneys and intestines, with focal necrosis of the liver and kidneys.

The cultural reactions of the isolated organism showed them to be practically identical with those of *B. suipestifer.* They were different from *B. paratyphosus A* and *B,* and *B. aertrycke.* By means of reciprocal agglutinin absorp-

tion tests, in addition to the cultural characteristics of the organism and the serological action of the patient's blood with *B. suipestifer*, the relation of the isolated organism to *B. suipestifer* is close enough to establish species identity. Unfortunately, the source of the infection was not determined.—J. T. Bauer, Margaret McClintock, *J. Infect. Dis.*, 44: 292 (Apr.), 1929.

Intramuscular Infection of Guinea Pigs with Spores of Cl. Botulinum—Evidence is given that with formalin as a tissue debilitant, approximately 25 viable heated spores of *Cl. botulinum* inoculated into the muscles of guinea pigs may grow luxuriantly and produce a potent toxin, and that *Cl. botulinum* sporulates readily in the debilitated tissues. Six-tenths to 0.8 c.c. of 10 per cent formalin (40 per cent) was the debilitant used. Using the same procedure, attempts to infect a series of laboratory rats with spores of *Cl. botulinum* were unsuccessful. Additional attempts to infect rats using saponin as the tissue debilitant also were unsuccessful. These unsuccessful attempts indicate the presence of antispore substances in the rats or failure to produce sufficient tissue necrosis, the author favoring the latter explanation.

No data are given as to the conditions necessary for growth of *Cl. botulinum* spores in the body; however, the author suggests that from the work of Coleman and Meyer (closed vein and eye culture) a condition of stasis as regards fluids in an organ and also the presence of a medium of necrotic and coagulated tissue may be favorable to spores' development.

The author also discusses the practical significance of his findings in regard to human infection by *Cl. botulinum* spores. He gives suggestive data which may have a bearing upon the absence of reported botulism due to war wounds. He also points out that many housewives are in the habit of heating canned goods suspected of spoilage and then consuming them. As some of this food may be a veritable culture of *Cl. botulinum*, the spores of which may not be killed by such heating, its consumption by a person having ulcerations or other severe lesions of the digestive tract might not be without danger; and he cites a Montana botulism outbreak caused by the consumption of soup, presumably heated, which was made from contaminated corn.—George E. Coleman, *Am. J. Hyg.*, 9: 47 (Jan.), 1929.

Development of Vitamin A during Ripening of Tomatoes—California tomatoes plucked from the vines green but mature, were divided into 6 lots as follows: (1) prepared at once, (2) ripened in light, (3) ripened in the dark, (4) ripened in ethylene, 1:2,000 parts for 1 week, (5) ripened in the dark with 3 periods of ultra-violet irradiation, (6) later taken from the vines in ripened condition. All lots were stored in jars with a layer of carbon dioxide with a temperature below freezing to prevent oxidation. Rats 21 days old after development of vitamin A deficiency were fed weighed portions of the tomatoes in addition to 0.5 gm. yeast daily with the basal diet. The experimental period was 56 days. The result showed the development of vitamin A in the ripened fruit compared to the green. There was practically no difference exhibited between the tomatoes vine ripened and those artificially ripened. Further experiments are in progress to determine quantitative relations of the fat-soluble pigments, carotin and lycopin, with chlorophyll, and vitamin A in tomatoes and other plants. It is suggested that carotin and lycopin have a protecting effect in the development of vitamin A in plants when exposed to sunlight.—Agnes Fay Morgan and Laura Lee W. Smith, *Proc. Soc. Exper. Biol. & Med.*, 26: 44 (Oct.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

JUDGING THE SUCCESS OF A DENTAL PROGRAM

ELEANOR G. MCCARTHY, S. B., D. H.

Consultant in Dental Hygiene, Massachusetts Department of Public Health, Boston, Mass.

IT is more difficult to measure success when dealing in terms of healthy childhood than in shares of stock or dollars and cents—difficult, but possible. Child health work is not unlike other projects—it has very definite goals—and while progress cannot be measured quantitatively, certain definite tests can be made to determine its general direction. While measuring rods are being developed that will show the difference between certain types of programs and grade the success of each, is there not some way in which each individual community may judge the success of its efforts? Wherever there are definite objectives, there must be success or failure.

In one phase of the community health program, the dental program, how can a community tell if its attempts to improve the condition of the children's teeth are successful? As realization of the benefits of stock taking on the part of the director and the staff is the first requirement, they must realize that any growing program needs its height and weight measured at regular intervals. It goes back to the fundamental matter of attitudes. The health educator, planning a dental health education program for a group of children, includes the attitudes that they should take toward good mouth hygiene as well as what they should know about their teeth and what they should do in caring for their teeth. Many health workers have overstressed the knowledge and the habits and have not realized that attitudes, intangible though they may be, determine the doing as much if not more than the knowledge.

DEVELOPMENT OF ATTITUDES

National and state organizations, whose privilege it is to guide communities in health matters, should consider the development of good attitudes as a most important part of their programs. Such organizations should determine the desirable attitudes toward community dental programs, and give that information to as many of the health workers as possible.

School dentists, school dental hygienists, and all public health nurses should have a clear conception of what the goals of the dental program are, and the difference between relief work of a temporary nature and corrective work so mixed with education that its benefits are lasting. Communities expect their workers to guide them, as they have the knowledge and training that is fundamental in this work.

All kinds of organizations are asked to assist in the campaign for better teeth and healthier mouths, and it is absurd to expect the directors of lay organizations to have a public health viewpoint in the matter. It is perfectly natural for them, for instance, to consider the ways and means of starting a dental clinic if the school nurse has mentioned repeatedly in her report the number of defective teeth and asked for aid in correcting the situation.

Offering clinic service to worthy chil-

dren is a logical activity of the private organization in question; but should it not consider the whole question—the whole program and its objectives—before laying plans for part of it, with any hope of success?

On the other hand, if an organization has conducted a dental clinic for several years without this preliminary discussion of objectives, is it not perfectly natural for it to measure success in terms of "total number of operations, visits, fillings, extractions and cleanings"? Public health workers are all familiar with annual reports of this kind.

Who is to blame in a situation like this?—A small wealthy community decides to conduct a dental clinic for all its school children; a program is planned, guided by the dental clinician, that is unusually good from the point of view of preventive dentistry. This program is continued for a period of 10 years; the problem of dental caries is practically under control; and the people in that community feel that they have a perfect dental program. They admit in the same breath, however, that they are worried because so few of the high school students take good care of their teeth!

To have all the children with teeth in good condition, saved by the early filling of defective enamel, kept clean, and cared for regularly by the school dentist and hygienist, is indeed success as far as a clinic is concerned; but the tragic part of this program is that the community is so wealthy that there is no need for a clinic. Practically every family could afford to have this work done by a private dentist. It is easier to appoint a dentist, and pay him, out of tax money, a small fraction of what they would have paid him as private patients.

This type of clinic is merely a means of getting dental service at low rates for all parents; it is not a community program, nor is it a public health project.

This may be an unusual case as far as the financial status of the community is concerned, but it is a typical case of the wrong attitude toward a dental program. It is, of course, the product of the era of dental clinics when the objective in everyone's mind was to correct existing dental defects if they were found to be affecting the general health and scholarship of the school children. It is "a menace to the child and an expense to the community."

The dental clinic based on a policy of prevention rather than repair has a very real place in the community dental program of today because practically every community has a certain number of children worthy of clinic care. The dental clinic should no longer be the main objective of the whole program, nor the main consideration when evaluating the success of a program.

Many new attitudes and new objectives concerning dental health work have been developed in the last few years. The communities with programs ten or fifteen years old are slow in adopting the newer point of view, but those communities that are considering the problem for the first time and those that are ever anxious to improve their present programs must consider these new attitudes before further progress can take place. While very little formal work concerning attitudes and objectives for a community dental program has been done, some suggestions are enumerated in the hope of stimulating some thought and action on this subject.

Desirable Attitudes—that should be taken by the community or organization in charge:

1. An interest in determining the objectives of a well rounded community dental program before starting any particular part of it
2. A willingness to develop the most permanent features of the program first
3. An interest in determining the actual needs before starting a dental clinic project
4. A realization that they may need expert advice concerning certain phases of the program

5. A realization that dental care is a personal or a family responsibility

Desirable Objectives—for the program itself:

1. To make available to every mother and father the best known means for caring for the teeth and mouth and preventing dental diseases
2. To teach the school children the care and importance of the teeth; help them to establish habits of regular care; and develop such attitudes as may be necessary for the carrying out of these habits throughout life
3. To determine existing dental defects among school and preschool children each year and notify parents of these defects
4. To correct existing dental defects by
   a. *Offering clinic service for needy children*
   b. Launching a general campaign to interest parents, dentists and the children themselves in having this work done

Once a community is made to realize the foregoing attitudes and objectives it should be ready to judge the success of its present program. Instead of asking an outside organization to evaluate the work for it, the community should attempt to determine at least some of the facts for itself.

The following list may help to indicate the kind of questions a community could ask itself:

The General Educational Program:

1. Do the average mother and father know the simple facts about teeth—their development and care?
2. What printed material is distributed to the homes?
3. What demonstrations, meetings or lectures have been held to interest mothers in this problem?

The School Program:

1. How many children go to the dentist twice a year? How many children go to the dentist when new teeth erupt?
2. Has dental hygiene a definite part in the health education program in the school?
3. Are good nutrition and regular dental care stressed in the teaching outlines for this subject?
4. How many children have formed the habit of keeping their teeth clean?
5. Do the students in the high school assume the responsibility of caring for their own teeth although helped by a clinic when in the primary grades?

The Dental Clinic:

1. Does the dental clinic serve only the children needing help financially?
2. Does it have a definite preventive policy, caring for the younger children first?
3. Is the amount of service sufficient to care for the poor children in at least the lower grades?
4. Do the parents pay part of the cost of service whenever possible?

Attitudes:

1. Are the children and parents interested in good teeth?
2. Do the parents consider the care of the teeth their responsibility or do they rely on the city for help, whether needed or not?
3. Are the various organizations in the community willing to coöperate with each other in building a well rounded program?
4. Do these organizations ask advice as to the latest methods of conducting dental examinations, dental clinics and other phases of the program?
5. Are they anxious to determine the success of their program so that they may seek to improve it?

A little wholesome introspection of this sort will not hurt any wide-awake community.

The following question summarizes this type of program: Is it wise to teach a child why he should care for his own teeth and interest him in doing so regularly, or is it wiser to care for his teeth for him without even explaining what you are doing? Incredible as it may seem there are many communities today carrying on the latter type of plan, and it is often called "successful."

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Ten Duties for Board Members—The following excerpt was originally presented as part of an address on "Function of Boards of Trustees and Committees," American Nurses' Association Meeting and Institute for Board and Committee Members of Nursing Organizations, Detroit, Mich., April 12, 1929:

1. To know why the organization exists and annually to review why it should exist.
2. To govern a board or a committee through joint thinking, not by majority vote.
3. To give money, or help get it, or both.
4. To face budgets with courage, endowments with doubt, deficits without dismay, and to recover quickly from a surplus.
5. To deal with the professional staff as partners.
6. To keep far enough ahead of the community to be progressive and close enough to it to be practical.
7. To interpret health work to the public in words of two syllables.
8. To deal with physicians on the assumption that the highest ideals of the profession dominate its every member and to face difficulties with recognition that both doctors and board members are human.
9. To be proud of a tradition but eager to improve it.
10. Always to combine a New England sense of obligation with an Irish sense of humor.

—Michael M. Davis, *Am. J. Nurs.*, XXIX, 6: 644 (June), 1929.

Frontier Nursing Service to Extend Territory—Public health nurses who have been fortunate enough to enjoy the hospitality and bring away some of the enthusiasm which abounds in the Kentucky mountains will be particularly interested in the *Fourth Annual Report of the Frontier Nursing Service.* The statement of the present financial status, an appeal for continued support and two objectives for the future are embodied in the brief foreword. Mrs. Breckinridge writes:

> There are two objectives the Frontier Nursing Service asks its supporters to keep in mind—one an immediate objective. We aim to treble our present territory and cover 1,000 square miles within the next four years. This will give us the statistical data Dr. Louis I. Dublin of the Metropolitan Life Insurance Company, who will tabulate it for us, considers necessary in order to demonstrate adequately that the work of nurse-midwives in remotely rural areas does lower the death rate of women and young children, and raise the general level of health of the population.
>
> Our second objective, once we have proved our purpose on a large enough scale to be convincing, is to raise an endowment which will enable us to carry our work into the length and breadth, height and depth of our American mountain ranges.

Feeding Fifty Folks More or Less—The summer number of the *Dairy Counciler* announces the advent of a new cook book. Not just a commonplace cook book this, with its bright cover and alluring illustrations which fairly make your mouth water, but an extraordinary one, for it caters to the imagination as well as to the palate. It is a compilation of recipes gathered together by Vera Armstead Hamilton, home economics graduate from Kansas State Agricultural College. Miss Hamilton is an experienced cafeteria director and consultant for church dinners and parties.

Public health nurses will eagerly seize upon this recipe book, especially if they are called upon to give advice or plan menus in quantities for home bureaus, community clubs, school lunches, junior clubs or camps.

Copies may be had for distribution from the National Dairy Council, 307 North Michigan Avenue, Chicago, Ill.

Asphyxia in the New-Born—In the June 8 number of the *Journal of the American Medical Association*, there is an article by Dr. Albert Mathieu and Dr. Albert Holman, in condemnation of the harsh and unscientific methods now used to resuscitate the new-born infant with atelectasis. They affirm strongly that the frail little body of the new-born infant is hurt rather than helped by the shocks of rough handling and cold water plunges. The method which they have used successfully and which they describe in detail in this article is based upon the fact that breathing is an involuntary process regulated by the brain center, by which carbon dioxide is given off by the blood and oxygen taken in. Although oxygen is necessary in the tissues and blood to allow the production of carbon dioxide, it is the accumulation of carbon dioxide which acts as a stimulant to the brain center. Asphyxia usually involves both low oxygen and low carbon dioxide content in the blood and tissues.

On this basis, a practical device has been worked out by which carbon dioxide (in mixture with oxygen) may be introduced into the trachea of the infant. The expired breath of the operator produces a satisfactory and convenient supply of carbon dioxide in mixture with oxygen, and a special catheter * with a trap is used, by which obstructive material may be withdrawn from the trachea and the carbon dioxide and oxygen mixture may be introduced.

The method is as follows:

Immediately after birth, the mouth of the infant is cleared of mucus and other superfluous material in the usual way. The baby is then placed on its right side and the cord is cut. If normal breathing does not start up after a short time or if attempts at respiration are evidenced by marked retraction at the costal margins without lessening of the cyanosis, the tracheal catheter is then used to remove any remaining mucus and fluid from the throat. It is then introduced carefully into the trachea and further fluid is withdrawn gently by suction by the operator. The catheter is cleared by blowing through it after its removal from the trachea. It is then re-inserted. The process of introducing the catheter into the trachea is easily learned. The writers state that their method is to have the baby's head supported over the edge of a table. The opening into the trachea is located by the right forefinger and the end of the catheter is guided in carefully under it.

The rate and force with which the operator sends air into the lungs is the most delicate part of the process. The operator should puff very gently about 40 times a minute and this should be kept up as long as the heart beats, until respiration is established. It may be repeated later if respiration fails again. It is extremely important that the baby's body heat be maintained through the entire process.

This method has given excellent results but, of course, does not work in cases of brain injuries and congenital deformities.—Dr. Albert Mathieu and Dr. Albert Holman, Resuscitation of the Asphyxiated Newborn. *J. A. M. A.*, 92, 23: 1917 & 1918 (June 8), 1929.—K. E. P.

Dedicated to Higher Education among the Colored Race—Of noteworthy significance was the statement made on June 19, 1929, when the Lincoln School for Nurses in New York City dedicated the new building to "its high purpose for the advancement and progress of scientific medicine among the colored race."

NEW PROGRAM OF HIGHER EDUCATION

In considering the future of Lincoln School as a center of higher education, 2 factors are outstanding: 1. The growing demand for its graduates as the health problems of the negro population

* The catheter is made by V. Mueller & Company, Chicago, Ill.

become more complex and more urgent. 2. The need, on the part of the graduates themselves, for positions of more responsibility, that they may utilize their training to the utmost and also develop their own latent capacities for leadership among their people.

To meet this twofold problem—Lincoln School for Nurses has adopted the following program as a guide to its activities in the immediate future. Details of this program will be carried out as rapidly as facilities, including financial resources, are available.

1. *Lincoln will coöperate with other movements organized to study and meet the needs of the negro population, especially those related to health*—It will make an intensive study of negro communities in the north, with the purpose of determining their need for nursing service.

2. It will expand its training of negro women by

(a) *Adding public health training.* All students will have four months' training along this line to include special work in the dispensaries, bedside nursing in the homes of patients from the wards and dispensaries, work in a communicable disease hospital, and field work in the Social Service Department of Lincoln Hospital and Henry Street Settlement. This training will be supplemented by *a course in principles of public health at Teachers' College.* Every effort will be made to develop qualities of leadership through this training.

(b) *Graduate courses in public health,* surgical nursing, pediatrics, midwifery, contagious diseases, administration. Scholarships will be provided for a limited number.

(c) *Effort to raise the standards of nursing education* in general, in the Lincoln School and other negro schools.

3. *Lincoln also proposes to develop a national placement service* for negro nurses, beginning with its own graduates This will include the development of opportunities such as the temporary subsidizing of a nurse in a needy negro community.

4. *An advisory service for negro nurses will be established* to aid them in securing training, in improving living conditions in positions held after graduation, and in other problems incident to their profession.

5. *Lincoln will invite affiliation with schools where training and experience are limited,* so that their picked students may take the last six months of their course at Lincoln.

Lincoln School is in a strategic position to carry out this program in full, because of its advanced equipment, its prestige as an institution of higher education and the standing of its graduates. Its association with Lincoln Hospital will be of increasing value, as the facilities of the hospital are enlarged according to present plans.

ERROR IN PUBLIC HEALTH NURSING PROGRAM

Through an error, the Thursday luncheon and afternoon sessions of the Public Health Nursing Section were listed in the Preliminary Program in the July JOURNAL (page 804) as closed sessions. These sessions, as well as all other meetings of this Section, are open sessions.

BOOKS AND REPORTS

Medicine. *Its Contribution to Civilization—By Edward B. Vedder, M.D., F.A.C.S. Baltimore: Williams & Wilkins,* 1929. 398 pp. Price, $5.00.

In the downpour of books on medicine and hygiene intended for the general reader, this one is somewhat "different." Not only is it couched in good language, but it is readable, the author possessing a subtle humor which frequently crops out, adding spice to the knowledge which is being imparted. One finds in this volume an accurate survey of what medicine has contributed to the world without any of the whoop and hurrah which too often accompanies such information, and without any of the misleading slogans which some of our boards of health have adopted.

While well balanced, it strikes us that Chapters I and VIII are particularly valuable, the first on the Causes of Disease, Predisposition, etc., and the last on Modern Preventive Medicine, which gives the story of the U. S. Public Health Service, and tells us what is going on. Curiously enough the average person accepts what is being done without any interest in knowing where it comes from. The reviewer is fond of asking students to whom they should apply for information on health subjects, or help along certain lines. Many of them do not even know that there are state boards of health, and except for the volumes of overheated air which emanate from Washington, many of them would never have heard of our Capital. We can hardly blame the average citizen for not knowing that Washington can furnish some real information, and that in the matter of health, it is the headquarters of the largest and best trained body of sanitarians in the world.

The book is beautifully printed, and can be heartily commended. A book of this type makes a reviewer feel that life is not simply a dreary drag of one thing after another. M. P. RAVENEL

Report of Fourth International Congress of Military Medicine and Pharmacy—*By W. S. Bainbridge, Commander M. C. F., U. S. Naval Reserve. Menasha, Wis.: George Banta,* 1927. Cloth. 248 pp.

The International Congress of Military Medicine and Pharmacy is assembled biannually for the purpose of collecting and standardizing methods employed in the prevention and treatment of disease and in the care of the sick and wounded in war and peace. The Fourth Congress was convened in Warsaw, Poland, on May 30, 1927, under the Presidency of General Stanislaw Rouppert, Surgeon General of the Polish Army. About thirty nations were represented. The United States delegation consisted of 5 medical officers, all of whom were members of the Reserve Corps of the Army or of the Navy.

The report as prepared by Commander Bainbridge is principally a compilation of official documents and communications presented to the congress on the subjects of Evacuation in Moving Warfare, The Etiology and Prophylactic Treatment of Influenza, and The Arsenobenzol Chemical Methods of Analysis and Estimation. Naturally, these subjects are considered from the viewpoint of military medicine, but contain much data of interest to those not directly concerned with military affairs. The papers dealing with influenza are good and

have a distinct public health interest. The reports on Evacuation in Moving Warfare should prove of value to students of the military phases of military medicine. The report contains a number of illustrations showing groups of delegates and views, most of which have not even the vaguest connection with the subject matter of the report. It is perhaps unfortunate that illustrations pertaining to military medicine as practiced in countries other than the United States were not used in lieu of some of those given in this book.

G. C. DUNHAM

Your Eyes and Their Care—*By Edgar S. Thomson, M.D. New York: Appleton.* 175 pp. Price, $1.50.

This little book is written with the hope of removing the disadvantages due to lack of understanding on the part of the usual uninformed person suffering with eye trouble. The aim is to give sufficient information that such a person may best coöperate with the eye physician. Dr. Thomson has admirably covered the subjects of anatomy and physiology without using too many technical terms. He gives the lay reader clear knowledge of what part of the eye is at fault, when the individual is nearsighted, farsighted, or astigmatic.

More such volumes from the hands of competent ophthalmologists will tend to offset vicious teaching now so common, particularly those misleading statements of charlatans that eye exercises improve vision of the nearsighted eye. Dr. Thomson makes clear that there is no inherent power to cause shrinkage or shortening of the globe which has already grown too long.

The frank discussion of squint is refreshing to lay people and commends itself to public health workers who are continually obliged to upset the teaching of old-fashioned doctors and of old-fashioned grandmothers about outgrowing squint (cross-eyes). This book emphasizes the fact that squint must be treated in the developmental period, that is, long before school age is reached.

Finally, public health workers will be pleased with Dr. Thomson's fine presentation of the relationship between malnutrition and disease of the eyes. Public health teachers have only begun careful observations in this field and it is well that an able clinician should lead the way in setting us right in his field.

A good deal of comfort will be afforded the sufferer with glaucoma or cataract by reading the chapters on these two subjects.

B. FRANKLIN ROYER

Dunn's Food and Drug Laws. Supplement January 1, 1929—*By Charles Wesley Dunn. New York: United States Corporation Company,* 1929. 228 pp. Price, $2.00.

Two-thirds of this paper bound supplement to the 3 volumes of *Dunn's Food and Drug Laws* are devoted to federal laws and regulations pertaining to foods and drugs, which were adopted during 1928, while one-third contains the new state laws and amendments of Alabama, District of Columbia, Louisiana, Massachusetts, Mississippi, New Jersey, New York, Rhode Island, South Carolina, and Virginia.

The volumes to which this is a supplement were reviewed and highly recommended in these columns in June, 1928.

J. A. TOBEY

The Writing of Medical Papers—*By Maud H. Mellish-Wilson, Editor of The Mayo Clinic Publications. (3d ed. rev.) Philadelphia: Saunders,* 1929. 184 pp. Price, $1.50.

The third edition of this book, the first of which appeared in 1922, under the name of Maud H. Mellish, will be welcomed. It has won its place as a standard. This latest edition has been increased in size, chiefly through addi-

tions to the list of medical journals and the abbreviations which should be used for them in references.

There are some inconsistencies to which attention must be called. On page 13, we are advised to "Use only English words and phrases," yet on pages 18 and 19 some 130 words and phrases, chiefly Latin and French, are given to show which are generally italicized, and which are not.

There is little question that words and phrases from foreign languages are often used in an attempt to show learning which has little existence in fact, and the advice to avoid such terms in general is good. However, some of them have become incorporated into our language, largely for the reason that there is no exact translation for them.

The section devoted to Standard Abbreviations for Medical Journals shows a number of inconsistencies as well as omissions. For example, the *American Journal of Physiology,* the *American Journal of Psychiatry,* and the *American Journal of Psychology* are incorrectly arranged. The *Clinical Journal* is placed below *Clinical Medicine,* as well as several others which it should precede. There are certain inaccuracies in abbreviations, as "Mental Hygiene," and "Jour. Ment. Pathology." The giving of "Mental" in full is not uniform with the *Quarterly Cumulative Index Medicus,* in addition to being inconsistent with the author's plan. The *New England Journal of Medicine* is still given as the *Boston Medical and Surgical Journal,* while no mention is made of the fact that *The Nation's Health* has been combined with the *American Journal of Public Health.* Among the omissions noted are *Physiological Zoology, American Journal of Science,* and *Journal of Nutrition.*

The book is well printed, and will doubtless hold its well earned position.

M. P. RAVENEL

Four Centuries of Medical History in Canada—*By John J. Heagerty, M.D., D.P.H. Toronto: Macmillan,* 1928. (2 vols.) 395 and 374 pp. Price, $12.00.

The author has rendered a distinct service, not only to Canada but to the medical profession in general. However localized history may be, it must contain lessons for the world in general, and the present volumes are full of material of wide interest.

The medical history of Canada goes back to the days of Francis I. The narration is unusually exact and well documented, since the Jesuit missioners kept daily records with meticulous care, which were sent to headquarters in France. The author has given us a picture not only of the early struggles of the French colonies centered particularly around Quebec, but also the development of medicine, surgery and public health in the various provinces, including Newfoundland, and the cities of the Dominion of Canada.

The first volume gives an account of the epidemic diseases—many brought in by the immigrants in ships which were overloaded and inconceivably lacking in the ordinary conveniences and decencies of life. We have an illuminating discussion of these epidemics, to which various names were applied. It seems clear, however, that yellow fever was one of the common scourges which went under the name of "ship fever," though the term included typhus, typhoid, plague, leprosy. and smallpox, brought from Marseilles where disease was common and from which many of the ships set forth for the French settlement of Quebec.

Another chapter deals with what was known as the *mal de la Baie St.-Paul,* the exact nature of which remains unknown, though the evidence is strong that it was syphilis widely disseminated extra-congenitally and in a form not known today.

Particularly touching are the accounts of smallpox among the Indians, and the courage of the priests who ministered to them.

The development of medical journalism, beginning with the *Quebec Medical Journal* in 1826, holds especial interest; but less than the foundations of medical schools, the first of which had its origin at the Montreal General Hospital in 1822; or hospitals, the earliest of which was instituted at Quebec in 1639.

There are many points of interest which the reviewer would like to stress, and would like especially to honor by name the pioneers who founded medicine in the new dominion, and those others who through 400 years have not only sustained the fair reputation of the profession, but have greatly extended it.

However, such books do not lend themselves easily to review. We can only advise that they be read, with the assurance that they have been written not only conscientiously, but with literary skill.

The printing and make-up are good.

M. P. RAVENEL

BOOKS RECEIVED

THE WRITING OF MEDICAL PAPERS. (3d ed.) By Maud H. Mellish-Wilson. Philadelphia: Saunders, 1929. 184 pp. Price, $1.50.

HYGIENE OF THE MOUTH AND TEETH. By Thaddeus P. Hyatt. Brooklyn: Brooklyn Dental Pub. Co., 1929. 64 pp. Price, $1.00.

DEVILS, DRUGS AND DOCTORS. By Howard W. Haggard. New York: Harper, 1929. 405 pp. Price, $5.00.

IN TRAINING FOR HEALTH. By C. E. Turner and Jeanie M. Pinckney. New York: Heath, 1929. 151 pp. $.72.

SCIENCE AND THE WAY TO HEALTH. By J. Mace Andress and Maud A. Brown. New York: Ginn, 1929. 367 pp. Price, $1.00.

A HISTORY OF THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY. By Colonel P. M. Ashburn. New York: Houghton Mifflin, 1929. 448 pp. Price, $5.00.

SUNRAYS AND HEALTH. Every Day Use of Natural and Artificial Ultraviolet Light. By Ronald Millar in collaboration with Dr. E. E. Free. New York: McBride, 1929. 124 pp. Price, $1.50.

AT HOME AMONG THE ATOMS. By James Kendall. New York: Century, 1929. 318 pp. Price, $3.00.

NUTRITION AND HEALTH. (6th ed.) Helen Rich Baldwin. New York: The Borden Co., 1929. 107 pp. Apply.

PROCEEDINGS OF THE FIRST COLLOQUIUM ON PERSONALITY INVESTIGATION. Towson, Md.: American Psychiatric Association, 1928. 102 pp. Price, $1.00.

PRINCIPLES AND PRACTICE OF ELECTROCARDIOGRAPHY. By Carl J. Wiggers. St. Louis: Mosby, 1929. 226 pp. Price, $7.50.

BUILDING THE BABY. By Carolyn Conant Van Blarcom. Chicago: Issued by the Public Service Office of the *Chicago Tribune*, 1929. 144 pp.

CLINICAL LABORATORY METHODS. (3d ed.) By Russell L. Haden. St. Louis: Mosby, 1929. 317 pp. Price, $5.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Aseptic Nursing—The application of aseptic nursing principles in one infant ward reduced respiratory diseases only 10 per cent over a control ward, and proved of no value in preventing the spread of an outbreak of varicella.

ABRAMSON, H., and BARENBERG, L. H. Respiratory Disorders in Infants. J. A. M. A., 92, 26: 2156 (June 29), 1929.

Malarial Mosquitoes—Problems of Anopheline mosquito control in irrigated regions in the Southwest furnish the basis for an interesting discussion of the malaria danger.

BARBER, M. A., *et al.* Malaria and the Malaria Danger in Certain Irrigated Regions of Southwestern United States. Pub. Health Rep., 44, 32: 1300 (May 31), 1929.

Malaria Transmission—Examinations of mosquitoes 3 days after biting malaria victims treated with plasmochin indicate that the drug is effective in controlling the sexual forms of the malaria parasite. The combination of the drug with quinine, which controls the vegetative forms, is discussed.

BARBER, M. A., *et al.* The Effect of Small Doses of Plasmochin on the Viability of Gametocytes of Malaria as Measured by Mosquito Infection Experiments. Pub. Health Rep., 44, 24: 1409 (June 14), 1929.

Toxoid or Toxin-Antitoxin—Another contribution to the controversy. In the experience of these authors, diphtheria toxoid as prepared by Ramon given in 3 doses is superior to 0.1 L + toxin-antitoxin mixture even when 5 doses of the latter are given.

DICK, G. F., and DICK, G. H. Immunization against Diphtheria. J. A. M. A., 92, 23: 1901 (June 8), 1929.

Smallpox Prevention—A thoroughly British discussion of the subject of vaccination brought up, not because of any possible administrative question, but because of an "uncomfortable feeling that our efforts to control smallpox cannot be relied upon to attain the end to which they are directed" because of the deficiencies of health legislation.

BUCHAN, G. F., *et al.* The Control of Smallpox. Pub. Health, 42, 9: 283 (June), 1929.

"Blood Will Tell"—Examples of family trees of patients are offered as support to the belief that characteristics breed true and exert an inexorable force for good or evil. This includes disease potentialities.

DRAPER, G., *et al.* Studies in Human Constitution. J. A. M. A., 92, 26: 2149 (June 29), 1929.

Appetite Loss in Childhood—Some of the causes, natural and otherwise, for the loss of appetite by children and how the condition should be treated is the burden of this entertaining paper.

GARLAND, J. Appetite Loss in Infancy and Childhood. New England J. Med., 200, 22: 1135 (May 30), 1929.

Constipation and Health—Having heard much about but having read nothing by Arbuthnot Lane, this latest "whole-meal" dissertation—really an exhortation—about constipation was read with great glee. Women will be surprised to learn that it is constipation that makes hair grow *on* their chins and *off* their heads.

LANE, W. A. The Prevention of Constipation. Canada Lancet, 72, 6: 218 (June), 1929.

An Influenza Epidemic—An account of an imported influenza epidemic in an isolated community—a university—giving an excellent opportunity to follow its course.

MILLER, F. N. The Influenza Epidemic at the University of Oregon in the Fall of 1928. Pub. Health Rep., 44, 23: 1353 (June 7), 1929.

Poliomyelitis Control—An impartial, well-balanced summary of our knowledge of infantile paralysis giving both sides of the several moot questions associated with the disease.

MORSE, J. L. The Problem of the Control of Infantile Paralysis. New England J. Med., 200, 24: 1246 (June 13), 1929.

Streptococcus Epidemicus—Reporting bacteriologic findings of studies pursued in connection with the Lee, Massachusetts, milk-borne epidemic of septic sore throat.

ROBINSON, E. S., and BECKLER, E. A. Bacteriologic Study of Hemolytic Streptococci from a Massachusetts Outbreak of Septic Sore Throat in 1928. J. Prev. Med., 3, 3: 237 (May), 1929.

Industrial Hazards—Rather superficial consideration of some of the industrial diseases without much about practical preventive measures.

ROLLESTON, H. Industrial Diseases and Their Prevention. J. Roy. San. Inst., 49, 11: 617 (May), 1929.

Longevity—"It is difficult to find much evidence that the average physical constitution in this country today is much more hardy or more enduring than fifty, one hundred, or one hundred and fifty years ago." These words close a Connecticut study of mortality, modern and colonial. Whether *any* evidence was uncovered is not clear, for we must admit a "skimming" of the paper only.

RUSSELL, F. E., and LUCIA, E. L. A Comparison of the Mortality in a New England Colonial Town with that of Modern Times. Am. J. Hyg., 9, 3: 513 (May), 1929.

Irradiated Ergosterol—Administered in large doses irradiated ergosterol proved to be highly toxic to rabbits, a condition not applying to small doses. The inorganic phosphate content of the serum was increased as was the calcium in certain tissues.

SMITH, M. I., and ELOVE, E. The Action of Irradiated Ergosterol in the Rabbit. Pub. Health Rep., 44, 21: 1245 (May 24), 1929.

Tuberculosis Mortality—The conclusion of a study of corrected mortality statistics in New York State is that the trend of rural and urban death rates (1900–1915) was essentially the same. Since the war and influenza epidemic both rates have declined more rapidly, somewhat more so in the cities.

SYDENSTRICKER, E. The Trend of Tuberculosis Mortality in Rural and Urban Areas. Am. Rev. Tuberc., 19, 5: 461 (May), 1929.

Diet and Longevity—The extension of life expectancy is confined to the early ages, little change having been effected in ages 50 and above. The chief influence in prolonging infant lives is nutrition, according to Professor Sherman's demonstrations, which are reviewed for popular consumption.

TOBEY, J. A. Diet and the Duration of Life. Am. Mercury, July, 1929.

Iniquities of Health and Welfare Agencies—"And how often do we find on perusing the yearly reports of a lay organization that much of the funds have been expended in organization work . . . while but a very small percentage . . . have actually b e e n used to alleviate suffering!" Many will want to ask the author; how often? And the endowments dispensing medical charity are well berated, too.

VANDER VEER, J. N. The Evolution of a Health Program. New York State J. Med., 29, 12: 732 (June 15), 1929.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Pittsfield, Mass.—The 1928 report of this city of 50,100 population shows careful preparation, good printing and progress. The new *Appraisal Form for City Health Work* has been applied and the results are tabulated. The employment of a full-time bacteriologist, continued diphtheria prevention work, and additional milk inspections are among the outstanding activities of the year. There were 4 cases of measles and 24 cases of scarlet fever, with no deaths; and 31 cases of diphtheria with 2 deaths, 1 fatal case coming from outside the city. A crude death rate of 13.0 (resident 10.98), an infant mortality rate of 49.6, and a birth rate of 22.9 are recorded.

Miami County and Troy, O.—The public health staff of the city of Troy and the county of Miami function largely as a unit. It is customary for the two Boards of Health of these districts to hold a joint annual meeting to discuss future plans, to agree upon personnel, and to determine expenditures to be made by each board. The employees thus serving the boards jointly are the health commissioner, clerk, sanitary inspector, a supervising nurse and a staff nurse. In addition, each department employs other personnel for special activities.

Approximately 50 per cent of the school population is protected by diphtheria immunization. During the year, regulations were passed making it compulsory that milk from only tuberculin tested herds be sold in the county. Clinics for examination of children of preschool age were held at each graded school building during the summer, and concentrated efforts were made by the department and the Parent-Teacher Association to secure the attendance of all children due to enter school in the fall. Sanitary surveys of several districts have been made by the Rockefeller Training Station at Greenville.

The estimated population of the county health district was 26,639, and that of Troy 8,172. The county reports a crude death rate of 11.8, and the city a rate of 15.0; while the infant mortality rate of the county was 65.7 as compared with 59.6 for Troy. Gross per capita expenditures amounted to $.37 for the county and $.86 for Troy, while the per capita income from taxation amounted to $.19 for the county and $.36 for Troy.

Scott County, Ky.—In communicable disease control, the 1928 report indicates progress, and it is gratifying to observe the absence of cases of typhoid fever and smallpox during the year. A list of 49 schools indicates 100 per cent vaccination of children in all but one school, and 96 per cent of these were vaccinated. There were 6 cases of diphtheria with no deaths. It is stated that 43 per cent of the school children have been immunized and the work is going forward with a goal of 75 per cent protected before the end of the present school year.

The child hygiene program has consisted of child health conferences, home supervision by a public health nurse and talks to mothers and community groups. Eighteen conferences were held during the year with an attendance of 217. Nutrition classes have been organized in the schools.

San Diego, Calif.—This city with an estimated population of 119,700 reports for 1928 a birth rate of 22.0 and a death rate of residents of 14.2. The principal causes of death were heart disease (431), cancer (257), chronic nephritis (195), pulmonary tubercu-

losis (164), cerebral hemorrhage (123), and lobar pneumonia (116). An infant mortality rate of 48 is noted.

A public safety committee, sponsored by the automobile club, made numerous suggestions for the betterment of traffic and reduction of accidents, among which were the widening of streets, certain changes in the Uniform Traffic Ordinance, the painting of white center lines on all main streets leading in and out of the city, and additional traffic signals.

During the year 2,530 children were immunized against diphtheria, a disease which shows a decrease of 65 in reported cases over 1927, the total reported being 91. Child hygiene work has increased, and 101 welfare conferences were held with an average attendance of 19. Excellent coöperation in school work is received from the Parent-Teacher Association.

Winona, Minn.—An attractive cover, good paper, careful preparation, appropriate headings, and interesting descriptive text characterize this 1928 report of the department of health. A foreword contains the following statement:

> The phrase, "Health is a purchasable commodity," is misleading. Sometimes health lost cannot be regained at any price. The knowledge necessary to conserve health is purchasable, but it must be purchased before health is sacrificed. Healthful living is the finest art of the science of life, placing on the individual an obligation to guard his health by adhering to high moral standards of living, and a responsibility for generations yet unborn.

The milk supply comes from dairies with herds tuberculin tested annually, and physically examined quarterly. Regular inspections are made of dairy barns, equipment, and milk plants. All milk handlers and those handling milking utensils are required to have health examinations. "It is not sufficient to deliver a good quality of milk to the city. The supply must be safe at all times. All milk sold in Winona is properly pasteurized."

It is noteworthy to find in this health department report brief discussions of the importance of ventilation, recreation facilities and child health day. This city with a 1920 population of 19,143 reports for 1928 264 deaths (37 non-resident), 483 births (114 non-resident), 19 deaths of infants under 1 year of age. There were 291 births in hospitals (60 per cent), while 56 were attended by midwives. There were 6 cases of diphtheria with 2 deaths, the first cases reported in the city in over 6 years. Stress is given in the report to the importance of immunization. Commendable work in infant welfare is reported. "Winona has an infant welfare nurse with the ability to coöperate with all of the physicians. By this coöoperation and the proper community interest shown, we may hope to lower materially our 1928 record of 38 per 1,000 live births."

A. I. C. P., New York, N. Y.—The 85th annual report of the New York Association for Improving the Condition of the Poor opens with an attractive child photograph followed by impressive statistics of services under the caption "What your contributions helped us to do during the year." These include 132,076 visits made by visitors and nurses to the homes of the families and to clinics and other institutions and agencies in behalf of families. Some 21,000 visits were made to the association's dental clinics, and 142 families were assisted by the mental hygiene clinic "in an effort to understand and solve their problems."

The report abounds in attractive photographs illustrating effectively the health and welfare activities of the association. It also deserves honorable mention for the interesting descriptive text, appropriate headings and good printing.

NEWS FROM THE FIELD

HAWAII SURVEY

PROF. Ira V. Hiscock arrived in Honolulu June 11 to inaugurate for the Committee on Administrative Practice of the American Public Health Association a survey of welfare work in Hawaii. He was greeted on board ship by a welcoming committee composed of the Secretary of the Chamber of Commerce, the President of the United Welfare Board of Hawaii, members of the Territorial Board, and other prominent persons. The survey, sponsored by the United Welfare Board, will embody a study of public health and social work in all its aspects. Invitations to participate in this appraisal of health work in Honolulu were received from F. E. Trotter, M.D., Territorial Health Officer, and from the Governor of Hawaii. Prof. Hiscock has been assured complete coöperation by all of the leading public and semi-public health agencies and kindred organizations. The field work will probably require from 6 to 8 weeks.

HOUSTON FLOOD MEASURES

FOLLOWING an unusually heavy rainfall on May 30 on the small catchment area of Buffalo Bayou, which meanders through the City of Houston, the main and central pumping plant of the city water supply located on the banks of this stream was completely inundated on May 31. The entire system supplies approximately 300,000 people with an average of 30,000,000 gallons per day and one-third of this comes from the Central Plant.

Quick work on the part of the local officials and sanitary engineers of the State Department of Health and the U. S. Public Health Service brought about immediate shutting off of these units and inaugurating a comprehensive program of rehabilitation and sanitary protection. In the meantime the city system was supplied with water from the 7 outlying pumping stations not inundated by the high water, which were supplemented by numerous private wells interconnected with the system including provision for reasonable pressure for fire protection. An intensive program of cleaning, disinfecting, and laboratory testing was inaugurated and now complete chlorination of all the water is in effect. Little actual damage is recorded due to the high waters in the south Texas area, although some high water records were established.

NEVADA ADMITTED TO U. S. BIRTH REGISTRATION AREA

THE admission of Nevada to the birth registration area was recently announced by the U. S. Bureau of the Census, the bureau tests having shown that birth registration in Nevada is now at least 90 per cent complete. The only states not yet included in the birth registration area are New Mexico, South Dakota and Texas.

STATE AND PROVINCIAL HEALTH AUTHORITIES

AT the 44th Annual Conference of the State and Provincial Health Authorities of North America, in Washington, D. C., May 31 and June 1, 1929, F. E. Trotter, M.D., president of the Territorial Board of Health of Hawaii, was elected *President* for the ensuing year. Other officers elected were: *Vice-president*, E. L. Bishop, M.D., State Commissioner of Health, Nashville, Tenn.; *Secretary-Treasurer*, A. J. Chesley, M.D., Secretary of the Minnesota State Board of Health, St. Paul,

Minn.; and *Field Secretary,* S. J. Crumbine, M.D., General Executive, American Child Health Association, New York, N. Y.

New members of the Executive Committee are Matthias Nicoll, Jr., M.D., State Commissioner of Health of New York, and the retiring president of the organization, and A. T. McCormack, M.D., State Health Officer of Kentucky.

Many members remained to attend the 27th Annual Conference of State and Territorial Health Officers with the U. S. Public Health Service. At this conference, the opening address was delivered by Surgeon General Hugh S. Cumming.

UNIVERSITY OF MICHIGAN

THE University of Michigan, at Ann Arbor, is holding a series of Public Health Institutes week-ends during the summer session, June 21 to July 27, 1929. Some of the lecturers are Marjorie Delavan, John Sundwall, M.D., Henry F. Vaughan, M.D., William DeKleine, M.D., C. C. Slemons, M.D., Lillian Smith, M.D., W. W. Peters, M.D., Louis I. Dublin, Ph.D., and many others.

THOMAS W. SALMON MEMORIAL

ANNOUNCEMENT is made by the Hon. George W. Wickersham, Honorary Chairman of the committee in charge, of the establishment of the Thomas William Salmon Memorial to provide recognition to the scientist who has made the greatest contribution in the fight against mental disease during each year. Awards are to be national and international and will provide for the wider dissemination of the knowledge of mental hygiene and insanity, through coöperation with the New York Academy of Medicine, in whose hands the administration of the $100,000 fund is to be placed.

A series of lectures will be given in various cities of the United States, to be known as the Thomas W. Salmon Memorial Lectures.

The movement was initiated by a hundred and fifty of the leading neurologists and psychiatrists of this country who have associated with them leaders in the mental hygiene movement and in psychiatric social service and nursing fields.

GREENVILLE AND DARKE COUNTY

ON June 6, 1929, Dr. M. E. Barnes resigned as Health Commissioner of Greenville, O. His resignation was presented to the Boards of Health of Greenville and Darke County at their regular meeting.

His resignation brought to a close the coöperation between the local boards of health, the State Department of Health and the Rockefeller Foundation. This coöperation was started in February, 1927, for the purposes of:

1. Developing a local health organization adequate to meet the health needs of a community
2. Expanding this work only to such a stage that the finances of the local boards of health could maintain it indefinitely
3. Using the health work thus organized and developed as a training station for health workers.

As these three objectives have been accomplished, the Rockefeller Foundation is withdrawing from the arrangement.

Dr. Barnes has been transferred to Lansing, Mich., to work with the Michigan State Department of Health. The Rockefeller Foundation is assisting this department in opening ten county health departments, as soon as they can train a staff for the work.

NEW CANCER CLINIC IN CHICAGO

A NEW clinic for cancer research will be opened in July in Chicago under the direction of many eminent doctors, among whom will be Dr. Charles Mayo of Rochester, Minn.

Final plans for the clinic were drafted

by Dr. Herman N. Bundesen, Chicago, and Anton J. Cermak, President of the Cook County Medical Board, who went to Rochester to see Dr. Mayo. The activities of the clinic will be carried out by a research staff to be assigned by Northwestern and Loyola Universities and the Universities of Chicago and Illinois.

DR. AMES NEW PRESIDENT OF JOHNS HOPKINS UNIVERSITY

JOSEPH Sweetman Ames, Ph.D., has been appointed the next president of Johns Hopkins University, Baltimore, Md., to succeed Frank J. Goodnow, LL.D., who becomes president emeritus. Dr. Ames has been connected with the university since his graduation from it in 1886.

EDWARD WILBER BERRY, DEAN OF JOHNS HOPKINS UNIVERSITY

THE new dean of Johns Hopkins University, Edward Wilber Berry, has no degree of an academic nature. He has been professor of paleontology and paleobotany at the university since 1917.

FRENCH HONOR AWARD

DR. Amedee Granger, director of the X-ray department, Charity Hospital, and director of the radiology department, Tulane University, New Orleans, La., has been awarded the gold Palmes Universitaires by the French Government, in recognition of his achievements in the science of radiology. This is the highest university decoration awarded by France and confers the title of officer of public instruction on the recipient.

HEALTH "MEASUREMENTS" IN PHILADELPHIA

THE American Physical Education Association will conduct a test in Philadelphia to "measure" the health of 10,000 school children. The purpose of this survey is to gauge the children's fitness, muscular development, neuromuscular coördination and ability to engage in healthful recreation.

NEW OFFICERS OF DELTA OMEGA

HON. Herbert Hoover, President of the United States, has recently been elected an honorary member of Delta Omega; Surgeon General Hugh S. Cumming and Dr. Frederick F. Russell were also honored in the same way. Dr. Charles V. Chapin is the only other honorary member of this society.

ILLNESS IN NEW YORK

THE Welfare Council, set up with grants from the Laura Spelman Rockefeller Memorial and the Commonwealth Fund, has published the results of a two-year health inventory, which reads in part as follows:

There are in New York City 125,000 to 200,000 persons ill in bed every day, and two to four times as many ill though not incapacitated. Several thousand die each year, many from preventible causes.

The yearly cost of care for the sick—doctors, hospitals, nurses, clinics, drugs, healers and appliances—is $150,000,000. The loss in wages due to absence from work on account of illness is $75,000,000 a year, and there is an even greater loss because of diminished productivity and other results of illness.

New York has 11,000 physicians, 12,000 nurses, 6,000 dentists, and 200 hospitals.

The rating of public health work in New York is 709 out of a possible 1,000 points on the American Public Health Association *Appraisal Form for City Health Work*, but this rating scale was devised chiefly for use in smaller cities and should not be taken as perfect for New York.

Copies of the complete report can be obtained from the Welfare Council of New York, 151 Fifth Avenue, New York, N. Y.

MICHIGAN PUBLIC HEALTH ASSOCIATION

THE midsummer meeting of the Michigan Public Health Association was held July 20 at the University of Michigan, Ann Arbor.

OUR IMMIGRANT FOODS

THE National Dairy Council has prepared an interesting item, showing where some of our food originated. Here is where some of them first came from:

Celery from Germany.
Onions from Egypt.
Pears and apples from Europe.
Spinach from Arabia.
Walnuts and peaches from Persia.
Cucumbers from East Indies.
Quince from Crete.
Radishes from China and Japan.
Peas from Egypt.
Horse-radish from southern Europe.
Ice cream from Italy.

PERSONALS

M. P. RAVENEL, M.D., University of Missouri, Fellow of the A. P. H. A. and Chairman of the Editorial Board of the *American Journal of Public Health and The Nation's Health*, was recently made an honorary member of Phi Beta Kappa at The University of the South, Sewanee, Tenn.

DR. EMMET F. CASEY has been appointed health commissioner of the village of Hillside, Ill.

DR. WILLIAM H. WELCH has resigned from the State Board of Health of Maryland after 31 years of association with it. Dr. Thomas S. Cullen has been appointed by the governor to take Dr. Welch's place.

DR. CURTIS H. LOHR has been appointed hospital commissioner of St. Louis, Mo., to succeed Dr. J. W. Shankland.

DR. THEOBALD SMITH retired on June 30 from the directorship of the department of animal pathology of the Rockefeller Institute for Medical Research. Dr. Carl Ten Broeck became the acting director in his place.

MRS. SIDONIE MATSNER GRUENBERG, director of the Child Study Association of America, sailed on June 7, to attend the Home and School Conference in London held June 28 and 29.

ARTHUR B. EMMONS, 2D, M.D., has recently become Executive Director of the Boston Metropolitan Chapter, American Red Cross, 45 Newbury Street, Boston, Mass.

DR. SHERMAN S. KATHAN, of Conklingville, N. Y., Health Officer of the Townships of Hadley and Day for twenty-five years, died in the Albany Hospital on May 12. He was the only physician in Conklingville.

DR. WILLIAM J. FLEMING, Health Commissioner of Troy, N. Y., since January, 1928, died on May 19.

GROVER A. WHALEN, Commissioner of Police of New York, N. Y., addressed the public over the radio on June 8 on "Enforcement as an Aid to Safety."

MAGNUS W. ALEXANDER, president of the National Industrial Conference Board, New York, N. Y., sailed for the Netherlands, to address the Fifth General Congress of the International Chamber of Commerce at Amsterdam, Holland, July 9.

GEORGE A. SOPER, PH.D., Consulting Sanitary Engineer, sailed on June 22 for Liverpool, England, to investigate the organization, methods and apparatus used by foreign cities in the collection and disposal of wastes. He will visit England, France, Germany, Austria and Italy.

DR. JAMES H. FLYNN was appointed Health Commissioner of Troy, N. Y., to succeed Dr. William J. Fleming, who died recently.

ALBERT L. MORGAN, Health Officer of Dexter, N. Y., for over 35 years, died on May 19.

IVAN C. WELD, Secretary-Treasurer of the International Association of Dairy and Milk Inspectors, died on March 15.

CONFERENCES

Sept. 26–28, Association of Military Surgeons of the United States, Denver, Colo.

Sept. 30–Oct. 5, American Public Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, American Child Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, International Society of Medical Health Officers, Minneapolis, Minn.

Sept. 30–Oct. 5, American Association of School Physicians, Minneapolis, Minn.

Sept. 30–Oct. 5, Northwest Conference of Child Health and Parent Education, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Sanitary Conference, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Public Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Organization for Public Health Nursing, Minneapolis, Minn.

Sept. 30–Oct. 5, American Social Hygiene Association, Minneapolis, Minn.

Sept. 30–Oct. 5, Conference of State Laboratory Directors, Minneapolis, Minn.

Sept. 30–week, National Safety Council, Chicago, Ill.

Oct. 14–18, American College of Surgeons, Chicago, Ill.

Oct. 24–26, International Association of Milk Dealers, Toronto, Can.

FOREIGN

Aug. 22–29, Adult Education Conference, Cambridge, England.

Oct. 16, International Conference for the Revision of International Classification of Causes of Sickness and Death, Paris, France.

Summer Problem No. 3—DIARRHEA

AGAROL is the *original* mineral oil—agar-agar emulsion with phenolphthalein and has these special advantages:

Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

Next to constipation, fermentive diarrhea is a most frequent problem in summer, especially in children and the aged. Thorough and regular elimination need consideration.

AGAROL

the original mineral oil and agar-agar emulsion with phenolphthalein, will prevent stasis, maintain normal elimination. No alkali, alcohol or sugar to cause difficulties. And Agarol is so palatable that children take it gladly.

Two regular size bottles are at your service for the asking. Send for them.

Maternity as a Public Health Problem*

MATTHIAS NICOLL, JR., M. D., FELLOW A. P. H. A.

Commissioner of Health, State of New York, Albany, N. Y.

BEFORE the advent of what is commonly called modern public health, health administration was comparatively simple; its field was narrow; and the duties and prerogatives of health officials were generally accepted without dispute, not only by the public but by the medical profession.

With the constant expansion of the field of public health, due to popular demand, unquestionably stimulated and rendered vocal and effective by the activities of official and nonofficial health agencies, the administration of public health is becoming increasingly difficult, largely because the borders of the field are continually impinging on the rights and prerogatives, real and fancied, of other official and non-official agencies. This leads to frequent disputes, bad feeling, lack of coöperation, working agreements, and all sorts of more or less futile compromises. Yet the health official, who seeks to limit his work to the quarantine and control of infectious diseases, the protection of water and food supplies, and such matters of routine as daily come to his attention, can hardly expect to keep abreast of the demands of modern life.

It is safe to say that the average health officer does not of his own volition seek to enlarge greatly the scope of his activity. Most of them would prefer to perform more efficiently the fundamental and essential work of their office with the production of more immediately measurable results than is usually possible in the majority of the newer fields; but the powers and responsibilities conferred by law upon health officers of larger jurisdictions are so far reaching and inescapable

* Presidential Address delivered before the State and Provincial Health Authorities of North America at the 44th Annual Conference at Washington, D. C., May 31, 1929.

that they cannot be avoided with self-respect and a sense of obligation to the oath of office.

Among the more recent activities in which health officers must engage may be mentioned the control of venereal disease, cancer, well baby clinics, periodic health examinations, and the reduction of maternal mortality. I have chosen the latter as a basis for some general observations—not that it is by any means the most important branch of public health, but because it presents a problem which includes possibly as many controversial elements as any of the others mentioned, and because no other phase of public health has produced more widespread discussion throughout the nation, or more heated arguments pro and con, than that of the care of the pregnant woman, involving as it does questions of federal and state financial policy, political expediency, personal prejudices, authority for the conduct of the work, and, most important of all, the control of methods of medical practice in the home and hospital.

Briefly stated, what is the problem which we as health officers are called upon to solve? In the 40 states and the District of Columbia, comprising the registration area for 1927, 13,837 women died from causes directly connected with childbirth. From a statistical standpoint, the figures themselves are not startling compared with those for the principal causes of death, but when the fact is taken into consideration that we are dealing not with a disease but with a physiological process, they are most disheartening, and a reproach to public health administration and its frequently vaunted claims of rapid progress in the achievement of definite results.

The deaths annually of 14,000 or 15,000 women from causes directly connected with childbirth, and the chronic invalidism of many times that number, constitute a much graver problem than an equal number of deaths among the general population or among infants and young children, since in a large number of cases the death of a woman in childbirth involves the disruption of a home, the future welfare of many dependent children, and other sociologic and economic factors, with which it is frequently very difficult to deal.

The definite recognition of maternal mortality as a public health problem in this country can be said to date from the enactment of the Sheppard-Towner Act, by which funds were made available to the states for work in maternity and child hygiene. Before that time little was done for the welfare of the expectant mother except in a few large cities and by unofficial organizations. During the last five years with greatly increased financial resources within the states, directly and indirectly as a result of the federal act, and an immensely aroused

public interest, especially among representative American women, the work has gone forward with a degree of success which is not easily estimated—certainly not statistically—and yet only the most prejudiced critic would dare to assert that no progress has been made toward the solution of what is and for a long time will be an extremely difficult problem.

As good Americans, we claim and frequently exercise the inalienable right to criticise and condemn our own shortcomings as a nation, and in this spirit most of us at one time or another in our moments of oratorical inspiration have called upon our audiences to witness the disgraceful neglect of expectant mothers prevailing throughout this country, resulting in a higher maternal death rate than in most of the civilized nations. This fact would seem to be proved statistically, and yet before permitting ourselves to indulge in too violent self-condemnation, let us be certain that the figures of other countries are as accurate as ours, and based on identical methods of allocating causes of deaths. Furthermore, those countries that show the lowest maternal death rate are very small in area compared with the United States, and contain a much more homogeneous population than that with which we have to deal. No nation, except ours, is called upon to face such a racial variation in fitness for motherhood. It can hardly be supposed that maternity work in certain states in the northwest is accountable for the low maternal mortality as compared with that of most other states; it is rather the physical development and habits of people of Scandinavian blood, among whom in their mother country the maternal death rate is exceedingly low, and, incidentally, lower than among the immigrants of that race and their descendants in this country.

In a recent pamphlet published by the Maternity Center Association of New York, N. Y., the problem with which we are confronted is summed up as follows:

> In the United States there are:
> 3,026,789 square miles of territory
> Whole communities without roads
> Wide stretches of territory without doctors
> 1,900 counties without a public health nurse (almost one-half of the counties in the United States)
> At any given time more than 2,000,000 pregnant mothers distributed over this vast territory.

Let me point out other inherent difficulties which we as health officers are facing, and will have to face for many years to come. I had hoped to present an analysis of the facts regarding some 3,000 maternal deaths in the State of New York, based on a questionnaire sent

out to all the physicians in the state in whose practice such deaths had occurred. Unfortunately tabulation of the results has proved much more time consuming than was at first anticipated. It may be of interest, however, to record the fact that more than 80 per cent of the physicians who were asked to fill in this confidential questionnaire responded promptly and fully—a splendid example of coöperation between the medical profession and public health authorities. The same kind of questionnaire sent to the various hospitals received far less consideration. A preliminary analysis of 696 replies received for the year 1925 brought out these facts among others:

Of the 696 cases, hospital care had been involved in 74 per cent, about half of which were delivered and died in the hospital, and the rest delivered in the home but died in the hospital later.

Only one-third of these cases reached full term; one-fifth were under 5 months gestation.

The lapse of time between the delivery and the death of the mother was as follows: In one-fifth of the cases death and delivery were practically simultaneous; in one-fourth there was a lapse of from 1 to 5 days between delivery and death; in one-fifth 6 to 14 days, and in one-eighth 16 to 50 days.

As to nationality—75 per cent were American born, 9 per cent Italians, and 4 per cent Poles.

Over 5 per cent were illegitimate births.

There were 230 questionnaires which stated at what stage the patient had entered the hospital. Only 13 per cent entered before delivery, 37 per cent during labor, and 50 per cent after delivery.

What chance did the doctors have as indicated by the number of days under care before death? To this question there were 483 replies. Fifty per cent had the case 1 week or less; over 10 per cent had the case less than 1 day; the balance were under care for varying periods, but only 13 cases were reported as having been carried the whole 9 months.

Only 16 cases were reported as having been delivered by a midwife, but others had a midwife in attendance at some time. A midwife was involved in 1 death, but was later exonerated.

As to prenatal care, 41 per cent failed to answer. Of the 408 answers, 65 per cent reported *Yes;* 35 per cent reported *No.* From the meager information as to the details of prenatal care, it was most difficult to gauge the effectiveness of such care. Judged by the generally accepted standards—the minimum standards as issued by the State Department of Health some five years ago—it would appear that few cases had enjoyed what might be termed adequate prenatal care. An attempt to ascertain when such care began showed that 34 per cent did not have prenatal supervision until the 7th, 8th or 9th month.

The most important fact to be derived from this analysis is that 74 per cent of these patients had been hospitalized, but that half of them had been delivered before going to the hospital, and later died therein. This represents a very high degree of emergency, with the

inevitable conclusion that the patients received little medical supervision until it was too late.

During the hearings on the Newton Bill before the Committee of Interstate and Foreign Commerce of the 70th Congress, the remarks of Dr. George W. Kosmak of New York were especially interesting. He represented, I believe, the state medical society, and is incidentally one of the dozen consulting obstetricians whose services the State Department of Health placed at the disposal of the county medical societies of the state by the use of federal funds. The object was the imparting by lectures and demonstrations to the general practitioners of the state an up-to-date knowledge of obstetrical procedures. Dr. Kosmak expressed the opinion that the work in maternal hygiene, as conducted in the various states under the provisions of the Sheppard-Towner Act, dealt too largely with what he regarded as the nonessentials of the problem, namely, prenatal care and instruction; that the question was largely one of obstetrical practice; and that failure to obtain more striking results in the diminution of maternal deaths was due in a large degree to bad obstetrical procedure. With the latter part of this statement I think most of us will agree; but that good prenatal and postnatal care cannot be characterized as a nonessential is adequately proved by the results which have followed well organized work in this field.

Through the courtesy of the Child Health Demonstration Committee of The Commonwealth Fund, I am permitted to call attention to the work of that organization in Clarke County, Ga., and Rutherford County, Tenn., from 1925 to 1928. This involves a group of some 5,000 women, approximately proportioned 2 to 1 as regards white and colored. Of these, 1,271 were under maternity care and 3,755 not under maternity care supervised by the health department. The maternal mortality per 1,000 live births in the combined group of white and colored, supervised and not supervised, was 9.4 (5.9 among the white, 16.4 among the colored); in the whole group not under official supervision 11.2 (6.9 among the white and 20.9 among the colored); under maternity care 3.9 for the whole group (2.6 among the white and 6.0 among the colored).

The cases under supervision in relation to maternal deaths include those visited by health department nurses for prenatal and, in most instances, for postnatal care. This is a striking example of what may be accomplished by thorough-going prenatal care, and presumably does not include supervision over the kind of obstetrical practice which these women received.

For what they are worth, data are submitted of the results among

approximately 1,000 expectant mothers attending the prenatal consultation clinics held by the New York State Department of Health during the past 5 years. By these it is shown that the mortality among mothers who visited these clinics was 14.6 per cent lower than the general puerperal mortality rate of the state, exclusive of the City of New York. The total number of deaths in this group was so small, however, that the figures in themselves cannot be regarded as of any great significance. Numerous other examples could be quoted of efficient and persistent prenatal and postnatal supervision which have produced definite results in lowering maternal mortality.

To return to the question of the practice of obstetrics as influencing maternal mortality—while undoubtedly the lives of a great many pregnant women are sacrificed annually in this country through the inaccessibility of medical care, or the entire lack of it, when the fact is considered that a large part of these deaths—certainly more than half—occur in cities and communities where doctors *are* available and *do* take charge of such cases, it is essential that the methods of obstetrical practice in this country be taken into account, however difficult it may be for health officers to ascertain the facts regarding them.

No one will question the oft-repeated statement, especially by members of the medical profession, that the teaching of obstetrics in most of our medical schools is totally inadequate. In many the instruction and experience afforded students is far less than that required of midwives in those states which supervise their work and license them. Indeed in some of our medical schools the faculties have not departed from the original conception that the practice of obstetrics is hardly a man's job, and can be mastered apparently by inspiration or after the observation of a few normal cases, in the actual delivery of which the student takes no part. The medical schools must then be held directly responsible for the kind of obstetricians which are being turned out in many parts of the country.

On the other hand, there has arisen of late years a school of meddlesome obstetrics founded on the practice and teaching of certain unquestionably skilled obstetricians, the popularity of whose practice is undoubtedly based on the very natural desire of women to be relieved in so far as possible of the sufferings of childbirth—even though among the more intelligent there must be knowledge of the additional risk to their lives and health, as well as to the children. These men have little or no regard for the processes of parturition which nature has perfected and which cannot be improved upon in a vast majority of cases. Yet some of them as a matter of routine resort to artificial methods of manual delivery; use instruments; and perform Cesarean

operations on the slightest provocation, or with none at all. I have had occasion to analyze the results of this kind of practice and, for one, am ready to state that in the broader sense it constitutes malpractice, even though it cannot be legally so adjudged.

As health officers, we are helpless to remedy this condition of affairs, and it is time that the organized medical profession should be empowered by law and stand ready to clean house in the interest of the lives and health of prospective mothers in this country. If they do not do so, the health authorities will be obliged to perform the task with a weapon, always at their command—pitiless publicity.

In the study that I have had prepared by the New York Division of Vital Statistics of death rates from specified puerperal causes in the original birth registration area from 1915 to 1925, omitting the years 1918, 1919 and 1920, which showed abnormally high rates owing to the prevalence of influenza, the following facts are elicited:

The death rate per 10,000 live births, due to accidents of pregnancy, increased on the average 2.4 per cent annually.

From puerperal hemorrhage 1.5 per cent.

Other accidents of labor 2.9 per cent.

Puerperal phlegmasia alba dolens, embolus, sudden death, 5.2 per cent, while deaths from puerperal albuminuria and convulsions decreased 2.0 per cent, and puerperal septicemia 0.9 per cent.

Incidentally, it may be stated that the mortality of infants from injuries at birth for the 10-year period 1915 to 1925 has risen on an average 3.6 per cent annually. If these figures mean anything—and they are based on a sufficiently large number of cases to be significant—they represent the results of meddlesome and unskillful obstetrical practice.

While progress is slow, the trend of maternal mortality in this country since the beginning of the campaign is definitely downward. The work of reducing maternal mortality differs widely from such procedures as immunizing the population against diphtheria; protecting a community against a water-borne outbreak of typhoid fever; or controlling infant mortality partly by means of the supervision of the milk supply. It is and always will be a more or less piecemeal affair. The cases are widely scattered throughout the country, and the conduct of a campaign must be based not only on general principles affecting the whole problem, but on racial peculiarities, and numerous other local conditions.

It is well to point out the fact that very little work is being done in the greater centers of population where, of all places, facilities should be at hand capable of producing definitely good results. It is

also of immense importance that knowledge should be forthcoming as to the kind of obstetrical practice afforded by hospitals of various types. Here again, the medical profession must assume the task in large measure. It will require independence, unselfishness, and a much greater indifference to that much abused term "medical ethics" than has hitherto prevailed. The work of public health education in regard to maternity must go on and be more effectively developed. Notwithstanding the criticisms to which it is constantly subjected it has produced and will continue to produce far-reaching results.

Many years ago Dr. Abram Jacobi of New York delivered an address in classic Latin before the Roman Medical Congress. If I remember correctly, he deprecated the then growing tendency to perform operations on the brain for the relief or cure of various pathological conditions. The title of his paper was *"Non Nocete"* (Do no Harm), an admonition which those who are responsible for the care of the expectant mother may well take to heart.

Tolerance

THERE is a limit beyond which abuse, misstatement, intolerance, and destructiveness must not be allowed to go. I hold no special brief for the medical profession. I realise that doctors, like the rest of us, have their failings. I am aware that privilege and vested interest may make some of them—sometimes—as selfish and intolerant as any. I tell them this at intervals, and admit, as greatly to their credit, that in spite of my abuse they continue to treat me with great friendliness and consideration; perhaps they do not take it too seriously.

Gratitude, however, for that friendliness is not the reason why I stand here today to defend them and their colleagues in the laboratories. Rather is it a sense of urgent necessity. When the beneficent work of the Medical Research Council is publicly denounced by a presumably responsible priest, when the use of radium, in the treatment of cancer, is openly described as an imposture by a qualified medical man who claims to have investigated it, and found it worthless forty years ago (9 years before it was discovered!), when the public is implored not to subscribe to hospitals lest its money be spent in torturing rabbits and guinea-pigs, when the greatest of human quests—the search for knowledge for the alleviation of suffering—is held up to obloquy by persons incapable of understanding or appreciating the beginning of what it means, then it is time for a counter-attack to be made.

. . . I do not propose, however, today to discuss only the fantastic opposition of the antivivisectionists. Their attitude of mind is only one aspect of a general phenomenon well known throughout history, a mild form of mental disorder, if you will, but one which has expressed itself from time to time in various hideous forms; in cruelty and persecution, in hatred and malice, in the perpetual treachery of hindering mankind in his slow and pathetic efforts to climb the ladder of civilisation.—A. V. Hill. From *The Lancet*, June 29, 1929, p. 1385.

Precision and Reliability of Underweight Measurement

C. E. TURNER, DR. P. H., FELLOW A. P. H. A.

Professor of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

THERE are two reasons for weighing school children. The first is the educational purpose of interesting the child in growing. It rests upon the realization that growth is a natural and continuous process and that the growth rate of children with good health and hygienic practices is better than that of children who are sick or who live unhygienically. The second reason for weighing school children has been to determine, in some degree, their health status by examining their height-weight ratio.

We are here concerned with the latter procedure, but it is desirable to point out at the beginning that the first or educational procedure is entirely separate from the second. It furnishes one of the best child incentives in the health education program and would continue to be useful even if the height-weight ratio as an index of health should be abandoned.

Can we assume that a child who is 10 per cent or 7 per cent below average weight for height and age is subnormal in nutrition or in health?

Can and should all children be brought out of this underweight group?

Can the effectiveness of a school health program be measured by the reduction in the number of underweight children?

These are important questions in determining certain phases of school health procedure. An examination of the nature and precision of the underweight measurement will help to answer them.

Children of the same height and age vary in weight for two reasons. The first is a difference in heredity, in nature, in skeletal proportions. The second is a difference in the amount of flesh, in nurture, a tendency toward emaciation or obesity—abnormal variations which are related to health or nutritional status. The presumption in the diagnostic use of underweight is that the underweight child has fallen below those variations which could be produced by the first

cause, and, therefore, must have something wrong with his health or nutrition.

AVERAGE WEIGHT—HOW ARE TABLES MADE?

Many standard weight tables have been made and an examination of these will show that each indicates a different average weight for boys or girls at each particular age. For example, 36 different tables give 33 different figures, ranging from 29 to 34.4 kg. as the average weight for boys 11 years old. In other words, when sets of tables are made the makers do not arrive at the same average weights.

We shall consider here the Baldwin-Wood tables. They were made from measurements of supposedly healthy children.* The process of making the tables includes, first, the weighing of many children without clothing and the determination of the average weight for each age-height group. A reasonable weight is then added for clothing and the resulting "average weight" is stated in terms of the nearest whole pound. (School people would do well to use the term "average weight" instead of "normal weight" whenever they refer to this figure because it is the average weight of a group of healthy children and does not indicate the weight which would be "normal" or "most desirable" for any particular child.)

Dr. Baldwin was good enough to send me some of the basic data from which his tables were made. Table I shows the number of children used in each computation. Table II shows the mean weights found for three age groups (7, 11, and 15 years) and the average deviations from these means. It will be seen, for example, that the average 11-year old boy varies from 2.6 to 10.2 lb. on one side or the other of the figure in the table according to the height group to which he belongs. Expressing such figures in terms of a percentage of the average weights we find that the average healthy 7-year old child varies from the mean by about 6 per cent, the 11-year old child by about 8 per cent, and the 15-year old child by nearly 10 per cent. Girls vary more than boys.

It seems apparent that a 7 per cent drop in weight below this average should not be considered as an indication of malnutrition since many supposedly healthy children show a variation as great as that. To be sure, some of these vary above the line, but an appreciable number in the Baldwin-Wood measurements must have been more than 7 per cent below the average weight. Variation in weight increases with age and one must expect to find many more 10 per cent underweight children among those 15 years old than among those 7 years old.

* No objective tests of health status were used in selecting the children measured.

We find, then, that the table does not indicate what a particular child should weigh, but an average weight from which healthy children vary rather widely.

In computing a child's relationship to average weight, his age to the nearest year and his height to the nearest inch are taken. One then looks up the average weight for the sex, age, and height as recorded in the table. The child's actual weight to the nearest pound is then divided by this figure and we say he is such a per cent of average weight. Whole units are used and this reduces precision.

The Age Factor—Ordinarily age is taken to the nearest birthday. Suppose a child is 10 years and 5½ months old on January 1; on February 1 he is 10 years and 6½ months. For purposes of computation his age has increased 1 year; actually it has increased 1 month. In schools where age as of a particular day in the calendar year is used, all children are underaged or overaged at particular weighing periods.

What difference will underaging or overaging make in the "per cent of average weight"? That may be determined for any particular case by referring to the Baldwin-Wood tables. The effect of underaging or overaging children under 8 years of age is slight, but after that time the number of children affected increases, and after 13 years

of age a change of 1 year in age would affect the "percentage normal" weight of the majority of children.

We have taken the trouble to compute the effect upon the "percentage normal" weight produced by overaging and underaging 1 year for boys and for girls at different age levels. Table III shows the maximum and minimum change in per cent from overaging 1 year at each age level. It may be as little as 0.75 per cent, or as much as 5.7 per cent. This tells us also the change which would be made in the percentage normal weight of a child who is given credit for being a year older when actually he is only a few weeks older. In other words, a child may become as much as 4 per cent or 5 per cent more underweight the day he becomes a year older. All children are not equally affected and Table III has, in the last column, a statement of the extent to which a whole population of children would be made underweight if they were overaged 1 year.

The Height Factor—What about changes in height? We use height to the nearest inch in computing the child's percentage of average weight. One often finds a child half way between the inch marks and wonders whether he should indicate the child's height as the lower inch or the higher inch in making the computation. How much difference does it make? What happens to a child's underweight status when he gains ¼ inch and gets credit for gaining a whole inch? By making sample computations from the Baldwin-Wood table it is found

that an added inch in height increases the extent of underweight by about 4 per cent. The use of whole inches may make an underweight figure inaccurate to this extent.

The Weight Factor—Weight is usually computed to the nearest quarter pound, but used as the nearest whole pound in making the com-

18	94.2	0.58	3.15	2.512

putation. Suppose you have a child just on the border line between one pound and another. If you choose the lower pound for your computation, he will be nearer up to weight than if you choose the upper pound, and the extent of the change in "percentage normal" weight will be represented by the fraction $\frac{1}{\text{the average weight}}$ which will usually amount to 2 per cent for younger children and 1 per cent for older children.

Combination of Factors—It is easy to secure from our data instances in which the whole units have combined either for or against an individual child. For example, one boy in January, 1921, was 100 per cent of average weight, or exactly normal. He grew at the expected or average rate in both height and weight, but because he slipped over certain whole units of computation though not over others, in January, 1922, he was found to be 94.3 per cent, or 5.7 per cent below average weight.

In another instance a girl who, in June, 1921, was 89.1 per cent of normal weight or nearly 11 per cent underweight, grew in both height and weight at the normal rate. Because of the accident of computation she was 96.8 per cent, or only 3.2 per cent underweight in April, 1922, and if we had used her height for a previous month, as is done in some schools, she would have been exactly normal weight although her body proportions could not have changed appreciably since her rate of growth in both weight and height was average. These differences arise because of the crudity of the measure.

Group averages of "per cent normal weight" are more consistent than individual figures, and yet if the individual determinations are crude so that they jump up and down from month to month, then obviously the averages are less significant because the individual variations are wide.

Shoes—Another factor which enters into the statistics issued by different school departments is that of shoes. In some schools children are weighed and measured with shoes; in other schools they are weighed and measured without shoes. We took the trouble to weigh 1,000 children* with shoes and without shoes, and Tables IV and V indicate the maximum, minimum, and average changes found.

For most children the percentage of average weight is greater when weighed and measured without shoes. That is, children in shoes are really like children on stilts. They seem taller and thinner. An inch of shoe does not weigh as much as an inch of boy. Therefore, the computation of the boy's relationship to normal weight shows him to

* Thanks are due to supervisors and teachers in Malden and Newton for making this possible.

TABLE IV

RELATION OF INDIVIDUALS TO "NORMAL WEIGHT" WITH AND WITHOUT SHOES

15	51	10	5	3	6.0

be "skinnier" in shoes than without shoes. That is not true in every case because sometimes the child, when he takes off his shoes, falls below the next pound level but not below the next inch level. He, therefore, is computed as being of less weight but the same height, in which case, of course, he seems to be more underweight with his shoes off.

Table IV gives the maximum increase and the maximum decrease in the per cent of average weight for both boys and girls at various ages. The maximum increase for the older boys and girls runs as high as 12 per cent. That is, some children were changed 12 per cent in their relation to average weight when weighed without their shoes. This is partly because of the accident arising from using whole pounds and whole inches.

The average effect of removing shoes is shown in Table V for boys, for girls, and for the combined groups. It raises the average "percentage normal weight" about 2 per cent and decreases the size of the 10 per cent underweight group by one-fourth to one-half.

POPULATION CHANGES IN UNDERWEIGHT STATUS

In our Malden Studies a significant increase was found in the rate of growth for the group of children who improved their habits. We did not find a statistically significant change in the average "percentage of normal weight." In the latter computation the slight improvement was less than the probable error. Similarly we found no significant change in the number of children who were in the 10 per cent underweight group. We were, of course, very careful to avoid any change in the method of computing the per cent underweight. We

always used the Wood tables, age to the nearest birthday, and height taken at the same time as weight with shoes on.

A few children did come out of the underweight group and reach average weight. These were children who were thin because of poor health or poor nutrition and who made definite improvement in their health. Frequently, however, we noticed improvement in health as shown by color, alertness, and greater freedom from fatigue when there was no appreciable change in the body proportions. The most frequent changes in the number of children in the underweight group arose among those children who were near the 90 per cent figure and who were thrown into the underweight group or out of it by the crudity of the computations already discussed.

Different communities present widely divergent figures concerning the number of 10 per cent underweight children in their school population. Many school systems which started weighing and measuring with the children's shoes on now have the shoes removed, and a still greater number of schools have changed from the Wood tables to the Baldwin-Wood tables. Height is usually taken only two or three times a year and many schools follow the unscientific practice of using the height for the last measurement in computing underweight during the succeeding months when new weights are secured. In a few instances one age is used for the child throughout the year, and this results in the underaging and overaging process with the effect upon underweight data which has been pointed out.

The Malden Studies showed no significant change in the underweight figures when the same technic of measurement and computa-

tion was carefully followed. How extensive would be the changes resulting from modifications in the methods of determining which children are in the underweight group? In order to answer this question we made 5 separate computations for the group of 10 per cent underweight children in the Malden Studies in February, 1922. Table VI shows the results of these measurements.

TABLE VI

PERCENTAGES OF CHILDREN IN THE 10 PER CENT UNDERWEIGHT GROUP WITH CHANGES IN THE METHOD OF COMPUTATION

March, 1922

239 Boys and 236 Girls

Method of Computation	Per Cent in Underweight Group		
	Boys	Girls	All
Wood Tables, March Age, March Height, With Shoes	20.9	29.6	25.3
Baldwin-Wood Tables, March Age, March Height, With Shoes	11.7	28.4	20.0
Baldwin-Wood Tables, October Age, March Height, With Shoes	10.9	26.7	18.7
Baldwin-Wood Tables, October Age, October Height, With Shoes	4.2	16.5	10.3
Baldwin-Wood Tables, October Age, October Height, Without Shoes	2.1	7.6	4.8

Using the technic which we followed throughout our experiment, 25.3 per cent of the 475 children under observation were in the 10 per cent underweight group. In changing to the Baldwin-Wood tables the size of the underweight group is reduced to 20 per cent. If we use October age, the figure is 18.7 per cent. If we use October height, it is 10.3 per cent. In taking off the shoes for the group (with changes indicated in Table V for the respective ages) the size of the underweight group was further reduced by 50 per cent. In brief, with one method of computation 25.3 per cent of the children were 10 per cent underweight. Making four changes in the method of computation only 4.8 per cent of the group were 10 per cent underweight.

SUMMARY

Height-weight-age tables show the *average* weight for children by height-age groups and do not show the ideal weight for any particular child.

There is a distinct difference in the standards set by the different standard weight tables.

The average variation from the mean for the supposedly healthy children used in the preparation of the Baldwin-Wood tables was approximately 6 per cent for 7-year old children, 8 per cent for 11-year old children, and 10 per cent for 15-year old children.

The computation of a child's "percentage of average weight" is inexact because of using weight to the nearest pound, height to the nearest inch, and age to the nearest year. In unusual cases a child may vary 7 per cent in relation to average weight because of the crudity of the computations and without any change in his bodily proportions. Fluctuations of 3 per cent or 4 per cent from this cause are not uncommon.

Wide fluctuations because of the crudity of individual computations are reflected in the average status of small groups and lost in the averages for large groups.

Inexactness, lack of reliability, and wide fluctuations in individual computations make the demonstration of minor changes in underweight status for a group of children uncertain, difficult and unreliable.

Children drop in and out of the underweight group without changing body proportions because of the inaccuracy of the computation. These facts supplement and further explain the previously published data from the Malden Studies' and provide a means of rationalizing these data with divergent data on underweight status from other sources.

The Baldwin-Wood tables show fewer underweights in a school population than did the Wood tables.

The increase in natural variability with advancing age produces an increasing number of 10 per cent underweight children in each higher grade when the health status is the same.

The removal of shoes in weighing and measuring may make an individual child more underweight or less underweight, but on the average it brings children from 2 per cent to 2½ per cent higher, and reduces the size of the 10 per cent underweight group by one-fourth to one-half.

Changes in the methods of collecting data or in the method of computation (such as removing shoes, changing tables, the method of taking height and the method of aging) constitute "balanced errors" which, singly or in combination, have a distinct and definite effect upon the underweight figures.

CONCLUSIONS

The schools should realize more clearly that standard weight tables give average weight, not normal weight, that there is a normal variation, and that some children must be below the average.

It is unscientific and unfair to set average weight as a goal for all children.

The 10 per cent underweight standard does not apply with the same significance to all age levels. The school should expect a greater number of 10 per cent underweight children in the later age groups due to the increased natural variability.

Since the natural variability of girls is greater than that of boys one must expect more underweight individuals among the former.

Seven per cent underweight is so close to the variation from the mean of average healthy children that it would seem to be unsuited for screening purposes. It may be that the 10 per cent underweight limit should be changed for older children.

The separation of 10 per cent underweight children is a rough screening. We should further divide this group by separating those children who are underweight because of slender build from those who are underweight because of emaciation, general ill-health or malnutrition. The public school should use its medical staff to make this separation. Further anthropometric tests should be developed and used as an aid in separating these two groups.

The school should not give up the regular weighing of children as an educational means of interesting them in health and in health practices. Emphasis should be placed upon gaining in weight each month and not upon the child's underweight status. The making of weight graphs and other classroom procedures should recognize this principle.

The failure to gain in weight over a period of several months is abnormal. Further studies should be made upon the consistency of gain in order to determine more accurately its value as an index of health. The practice in school administra-

tion which brings to the attention of teacher, nurse, or doctor the child who fails to gain in weight over a period of 3 months would seem to be commendatory.

Regular gain in weight month by month should assist in relieving anxiety concerning the health of an underweight child.

The percentage of 10 per cent underweight children in two communities cannot be compared unless the method of gathering data and the method of computation are known to be the same.

Communities weighing and measuring children without shoes will have only half or three-fourths as many 10 per cent underweight children as communities weighing and measuring with shoes.

A reduction in the size of the 10 per cent underweight group in a school population has no significance unless it is known that there have been no changes in the method of gathering and computing data.

Changes in the size of the 10 per cent underweight group do not constitute a reliable measure for the success of a school health program.

In the hands of the physician underweight is one of the valuable diagnostic factors. The separation of underweights in a school population for further medical attention may be a valuable screening process. That underweight in itself does not constitute a complete diagnosis is now becoming more widely recognized by the lay public. It would be extremely unfortunate if the data presented above were used to discredit either the scientific medical use of underweight or the practice of weighing children regularly in school as an educational procedure.

Contagiousness of Leprosy

IN a group of 100 Louisiana lepers hospitalized more than 15 years ago, it has been disclosed from subsequent records that in 64 instances only one leper in the family developed the disease, while in the 36 other instances leprosy occurred in 83 additional relatives. There were 14 instances in which the disease occurred in a mother and one or more of her children; 15 instances in which the disease was found in sons of lepers; 21 instances in which the disease was found in daughters of lepers; 38 instances in which the disease was found among brothers and 31 instances in which the disease was found among sisters. In addition the following number of cases occurred in less closely related members of the family: 8 uncles, 8 aunts, 18 nephews, 9 nieces, 5 grandfathers, 3 grandmothers, 6 grandsons and 5 granddaughters. In some families the disease has invaded certain branches to the point of extermination.

Instances of the occurrence of leprosy in families have also been noted in cases from other states than Louisiana. It has not invariably happened that the parent became infected before the child; indeed, the reverse frequently occurred. Intimate contact for many years was common where there was more than one case of leprosy in a family. In many instances several contacts with leprosy also existed. In 5 cases the incubation period is calculated as not less than 6 years.

Antirabic Immunization with Desiccated Vaccine

D. L. HARRIS, M. D., FELLOW A. P. H. A.

St. Louis, Mo.

DESICCATED rabies vaccine has been used since 1912 for the immunization of men and dogs. The results and data are now reported, to permit a critical comparison of the value of this with other methods employed by various investigators in this country and elsewhere.

Shackell and Harris[1] found that if rabies vaccine were frozen to — 10° C. and then dried in vacuo over sulphuric acid, about 2 per cent of the infectivity could be preserved for several months. Harris,[2] continuing this work, showed that the proportion of virus remaining alive after desiccation depends entirely upon the degree to which the material is frozen. Fixed virus, frozen with liquid air and then dried, retains 90 per cent of its infectivity. When frozen with CO_2 snow and dried in vacuo over sulphuric acid in a jar which is kept at a temperature of — 15° C., the resulting product retains more than 50 per cent of its original infectivity.

In the original method the brain and cord was mixed with CO_2 snow and ground in a mortar. This resulted in frequent bacterial contamination, to avoid which a jacket was welded around a steel mortar, leaving a space between the walls. The CO_2 is now passed into and through this enclosed space, and the mortar is chilled without direct contact of the brain with the snow. In all other respects the preparation is carried on as heretofore described in detail.

Repeated experiments showed that subdural injections of 0.004 mg. of this desiccated material would regularly infect rabbits with the usual incubation period. It was further established that the subsequent rate of loss of infectivity depends upon the temperature at which the product is stored. When kept at — 1° C. the material has been found to be infectious for at least 3 years. One lot, dried and sealed in vacuo October 19, 1920, produced typical symptoms in 2 rabbits inoculated on October 27, 1923.

In a series of experimental inoculations to determine the rate of loss of infectivity I found that those rabbits which were injected with a quantity too small to infect acquired an immunity against a subse-

quent injection of a lethal dose of fresh virus. Since publication,[2] these results have been repeatedly confirmed, and the fact has been established that rabbits injected subdurally with non-infectious desiccated vaccine can later withstand a subdural inoculation of several hundred lethal doses of fresh virus.

In other words, the virus which after long preservation in vacuo becomes non-infectious, still possesses immunizing value. This, however, slowly diminishes and after a time disappears completely. The lot described above which was proved to be infectious 3 years after its preparation was found to have lost all its immunizing property 5 years later (1928).

In 1917, owing to a frequent bacterial contamination of the brain which was thought to be due to the trephine wound, I began to inoculate rabbits by inserting the needle through the optic foramen. Whether due to this procedure, or to the long preservation of the virus in the cold, or to some unknown factor, it was found in 1918 that many rabbits failed to develop the disease when inoculated with virus which had been kept in vacuo for longer than 3 months. This resistance to desiccation gradually lessened, so that in 1920 all infectivity of the vaccine disappeared after storage in vacuo for 2 months, without, however, any impairment of its immunizing properties, as shown by repeated tests on rabbits.

This rapid loss of infectivity necessitated a complete change in the original method of immunization, which consisted in the injection of increasing quantities of vaccine somewhat similar to the method of Högyes.

Having in mind Pasteur's theory that the injection of non-infectious cord protects against the subsequent injection of virulent cord, and that this in turn produces a degree of immunity sufficiently high to protect against the danger due to the bite of a rabid animal, I changed my scheme of treatment, giving 5 daily doses, 25 mg. each, of non-infectious vaccine of the old strain (A), and followed these, in ordinary cases, with 5 similar injections of a new and resistant strain (B) partly attenuated by preservation in vacuo for 3 months. This fresh strain secured from William H. Park, M.D., of New York, N. Y., was tested and found, as already noted, to remain infectious in vacuo for at least 3 years.

During the past 8 years, immunization has been based on this plan, and experience has shown it to be adequate for superficial bites. This last strain (B) has as yet shown no altered resistance as the result of repeated desiccation.

In the treatment of persons severely bitten on the hand the usual

course consists of 5 injections of the old strain (A), and 8 to 10 injections, of 25 to 35 mg. each, of the new (B), depending upon the extent of the bite and the number of days elapsed before treatment is begun.

After bites on the head and face, particularly when extensive or lacerating, 2 injections are given daily for 10 days, and the total amount administered is from 2 to 3 times that of the usual quantity.

Two examples will illustrate the present scheme of intensive treatment.

Case I—A farmer, age 28, was deeply bitten on the left hand and wrist by his own dog, October 6, 1926. The dog also bit 2 cows, and disappeared. These cows developed typical symptoms of rabies 2 months later and died. On December 17 treatment of the farmer was begun and it was continued intensively for 10 days. As shown in Table I, within the first 24 hours he was given 120 mg. (A), and during the next 9 days, 570 mg. of the infectious vaccine (B) which had been dried only 2 months previously and had therefore lost but little of its infectivity.

Case II—A boy, age 5, was severely bitten on the face, January 31, 1922. There was one deep wound over the left eyebrow, one on the chin, and a more superficial wound on the nose. Examination of the dog's head in the City Board of Health Laboratory had failed to show the presence of Negri bodies, but a guinea pig inoculated at the time developed symptoms 11 days later. Negri bodies were numerous in the brain. The boy was first brought in and treatment begun on the 13th day after the bite, 350 mg. of (A) being given during the first 72 hours. During the next 7 days, he received 350 mg. of (B) (see Table II).

During the past 17 years this vaccine has been given to 3,516 persons. In Table III will be found data on 2,032 of those treated.

Most of the treatments were sent by mail to the local physician with an enclosed questionnaire, but because in a large number of cases the physician either did not answer the questions as requested, or answered incompletely, the data in 1,484 cases are either entirely lacking or are too meager to justify their inclusion in this report.

TABLE III

DATA OF 2,032 CASES TREATED FOR RABIES

	Head	Hands and Forearm	Body and Lower Extremities	Contact	Total
Rabid	147	617	355	334	1,453
Probably Rabid	30	174	104		308
Unknown	19	100	87		206
Probably not Rabid	8	40	17		65
Total	214	931	563	334	2,032

Of all those treated, there has been only one failure. This was a farmer who, following a severely lacerating bite on his hand, July 1, 1913, began the treatment 5 days later. An intensive treatment was given for 7 days, but the patient insisted upon returning home for harvesting work. After a week of hard labor in the field during excessively hot weather, symptoms of rabies developed on the 20th day after the bite, the 14th day after the first injection.

I believe an important factor in our success is the intensive treatment given to all severely bitten patients.

One case of temporary post-vaccinal paralysis, occurring after a 10-dose treatment, has just been reported to me, but as yet I have not been able to obtain all the details.

No intensively treated patient has shown any paralysis. In my own personally treated cases reactions have been limited to local redness and swelling which disappeared promptly.

PROPHYLACTIC IMMUNIZATION OF DOGS

The prophylactic immunization of dogs presents an entirely different problem from that of men. The latter is one of necessity, while the former is a voluntary act for the prevention of a rare disease which is unlikely to occur. There are 2 prime requisites for a vaccine used as a prophylactic in dogs: first, its use must never result in the production of the disease itself; second, the immunity must be adequate to protect the animal, should it be exposed. The preparation must also be stable to permit distribution to veterinarians.

We believe that all of these requisites are found in our product. In its use in experimental work and in practical immunization of dogs,

not one of the animals has been infected by the vaccine and, so far as can be learned, no immunized dog has later developed rabies.

In all the earlier work the scheme for immunizing dogs followed that used in men. Beginning in 1915, dogs were given 6 injections of attenuated vaccine containing 125 mg. of the virus. Since 1920, when the method of dosage in men was altered, 300 dogs have been immunized with 3 injections of 30 mg. each of non-infectious vaccine (A), followed by 3 equal doses of the new (B) strain of attenuated virus.

It was evident, however, that 6 separate injections would be impractical and prevent its general use. Experiments were therefore undertaken to give the entire quantity in 2 doses—90 mg. of (A) followed 8 or 10 days later with 90 mg. of attenuated virus (B). These tests made on dogs, rabbits and rats have proved uniformly successful and entirely free from danger.

In one experiment 10 white rats were injected subcutaneously with 75 mg. of vaccine (A) and 5 days later were injected with 100 mg. of (B) which had been stored for 1 year in vacuo. At the same time 6 white rats were injected with 200 mg. of the same lot of (B). Twenty days later these 16 rats, together with 8 controls, were injected in the muscles of the neck with 1 c.c. of a thick emulsion made from the fresh brain of a dog that had died of rabies.

Four of the controls died of rabies. Negri bodies were found in their brains. None of the immunized rats developed rabies.

In a second experiment, 45 young white rats were injected subcutaneously with 200 mg. each of vaccine (B) which had been kept in vacuo for 8 months. Not one of these showed any symptoms of rabies during an observation of 3 months.

In a third experiment 28 young white rats were injected subcutaneously with 100 mg. each of virus (B) which had been kept in vacuo 27 days. Twelve days later 1 rat died, but no Negri bodies could be demonstrated in the brain. The others remained well for 3 months, when all were killed.

It is evident from these experiments that even in relatively large doses the vaccine is not infectious to white rats when given subcutaneously. The possibility that 1 rat may have developed rabies after a primary injection of (B) which was not attenuated, and which had not been preceded by the injection of a dose of non-infectious vaccine, is sufficient to justify the rule that no dog should be injected without a preliminary dose of non-infectious vaccine and that the second injection should always be with material whose infectivity has been somewhat lessened by storage in vacuo of at least 3 months.

Fifty dogs have been immunized by giving the vaccine in 2 doses. Not one of these animals has shown any symptoms of rabies, or any ill effect from that treatment.

Schoening's[3] experiments, and the fact that during the past year I have seen 5 rabid dogs which had been injected within less than a year with a single dose of phenolated vaccine, lead me to the conclusion that the degree of immunity resulting from a single injection of a killed vaccine is not adequate to protect a dog against all strains of street virus, and that the feeling of security from its use is not justified. As it has been found in distemper that dogs cannot be adequately immunized unless given a killed vaccine and a subsequent injection of a living virus, so I believe it will likewise be found in rabies that an effective immunization of dogs cannot be obtained by the use of a single injection of a killed vaccine. This should be reinforced, as in distemper, with a second injection of an attenuated but living virus.

CONCLUSIONS

In a total of 3,516 antirabic vaccinations, the uniformly successful treatment of every patient bitten on the head or face, with only 1 failure following a bite on the hand, warrants the conclusion that antirabic immunization with desiccated vaccine is as effective as by any other method.

Prophylactic immunization of dogs, to be effective, should consist of an injection of a non-infectious vaccine, reinforced later with a second injection of an attenuated but living virus.

School Psychologists in Switzerland

IN addition to the school medical service of Basel, which has been in existence for some years, the administrative authorities of that city recently appointed a physician as "school psychologist." The school psychologist will make psychological examinations of the pupils and prescribe treatment when necessary. Among his duties will be the determination of the causes of unsatisfactory school work and examination of children recommended by the teachers or physicians for special classes, such as classes for specially gifted children, or for backward children, or for those with certain physical or mental defects.

The school psychologist also will aid the vocational adviser by making the necessary psychological tests.—*Pro Juventute*, Zurich, Nov., 1928, p. 416.

Antirabic Vaccination by Means of Desiccated Virus

RIGNEY D'AUNOY, M. D.

Department of Pathology, Charity Hospital of Louisiana, New Orleans, La.

FOR 18 years these laboratories have administered antirabic prophylactic treatment with material prepared along the lines indicated by Harris. We desire to tabulate the cases treated during the past 14 years, and to add a few observations that have been made on various properties of desiccated virus. As some modifications have been made in the technic proposed by Harris, it may be of value to describe briefly the methods used in the production, storage and administration of rabic virus, for the greater part of the time covered by this report.

Full grown, healthy rabbits, averaging 2,200 gm., are inoculated intracerebrally with an emulsion of desiccated fixed virus, the amount used being usually 0.004 mg. of material in 1 mil of sterile physiological salt solution. Injection is made after trephining, the material being deposited by means of a 24-gage needle, directly into the lateral ventricles. After 6 or 7 days the animals develop typical symptoms, and when complete paresis has intervened they are killed by ether narcosis.

The cord and brain are removed under aseptic conditions, stripped of their membranes and placed in a sterile mortar. Carbon dioxide snow is then added with constant mixing and trituration until first solidification, and later rather fine division have taken place. The ground material is spread in a thin layer over a cold sterile porcelain perforated plate that fits within a 25-cm. pyrex glass Scheibler desiccator previously sterilized and kept for a few hours at a temperature of — 12° C. A layer of sulphuric acid or phosphoric anhydride 2 cm. deep covers the bottom of the desiccator, and acts as dehydrating agent. A vacuum of 2 mm. of mercury is quickly produced within the desiccator, and it is stored at a temperature of — 12° C. to — 18° C. If the material has been spread in a layer averaging about 5 mm. thick, no difficulty is experienced in accomplishing desiccation within 48 hours.

The material is then scraped off by means of a sterile spatula, collected in a sterile mortar, and pulverized. The finely powdered material is placed in pyrex glass tubes 125 mm. long by 10 mm. in diam-

eter. These tubes are quickly sealed by flame and stored in a dark place at a maximum temperature of — 10° C., the usual temperature averaging between — 12° C. and — 15° C.

Notwithstanding the care exercised in preparing the virus, it is conceivable that at times bacterial contamination may occur. It is possible, however improbable, that spores of such organisms as *Clostridium tetani* may be in the carbon dioxide snow. Although the injection of such spores in man would, certainly in the great majority of cases, be followed by no ill effects, we have assured ourselves against such happenings by cultural control of every batch of virus prepared. Aerobic and anaerobic cultures are made from material obtained from each animal used, and also from each tube of completed virus. It is believed that these precautions have not been taken in vain, as we have never even experienced localized infections after subcutaneous injections of virus so prepared and so controlled.

STANDARDIZATION OF DESICCATED VIRUS

It has appeared necessary to establish arbitrary standards in dealing with desiccated rabic virus. So little is known of the agent concerned that the problem is one of great difficulty. The established methods of standardizing on the basis of protection, or on the basis of neutralization of toxic substances are, of course, not applicable. Throughout his work Harris used as a standard a " unit " which represented the smallest amount of desiccated material necessary to infect a rabbit. We employ a similar standard, designating it the " minimal infective dose," and defining it as the least amount of desiccated material which within 5 days after preparation and when kept at temperatures of — 12° C. to — 15° C. will cause paresis in a 2,400 gm. rabbit within 7 days following intracerebral injection. It is not claimed that this standard is of any great degree of accuracy, as naturally a number of factors enter into the question of infection. However, it is believed to be an advantage to have some fixed unchanging basis on which to establish the degree of infectivity of any particular batch of virus. There is no difficulty in producing a virus with a " minimal infective dose " of between 0.002 and 0.004 mg. when desiccation has been accomplished within 48 hours. If it has taken longer, the number of " minimal infective doses " will be greatly reduced per unit of material.

Desiccated virus may be kept in the dark at temperatures of — 12° C. over long periods without demonstrable loss of infectivity. One lot so stored contained the same number of " minimal infective doses " per mg. as when prepared 6 years previously. At refrigerator

temperature (8° C. to 12° C.) infectivity may last approximately 3 years. At higher temperatures, infectivity is rapidly lost, never, in our experience, lasting longer than about 60 days at room temperatures (23° C. to 28° C.). We do not believe that there is any relation between infectivity and immunizing power.

METHODS OF ADMINISTRATION

Treatment has been carried out by administering subcutaneously an initial dose of 250 " minimal infective doses," doubling the quantity daily until a maximum of 2,000 was reached. We never consider the ratio existing between infective and non-infective material in the virus used. As a rule, the virus is 2 or 3 months old before use, but as it loses practically none of its infective power during that time, we are always dealing with a freshly prepared virus as far as infectivity is concerned. Usually a total of 11 treatments of 17,750 minimal infective doses are given, except in severe penetrating injuries of the face and scalp, when 15 treatments, or a total of 25,750 minimal infective doses, are given. In children under 3 years of age one-half the amount is administered.

During the last 14 years 5,125 patients have been treated with virus, generally prepared as outlined. Tables I and II show the treated cases and sites of injury by proven rabid animals. Table III classifies the treated cases according to age.

DIAGNOSIS OF RABIES

In this series, positive diagnosis of rabies was made only on finding Negri bodies (microscopic test), or on production of clinical rabies after intracerebral inoculation of test animals (biologic test). This latter we have discarded. With infected, decomposed brains it is useless, as invariably the test animals succumb to purulent meningitis when injected with such material. With satisfactory material it is too time consuming. Examination of brain sections, preferably cerebellar, prepared by a rapid fixation paraffin embedding method, and stained by Mallory's aniline blue, has been found the diagnostic method of choice.

POST-VACCINAL COMPLICATIONS

About 25 per cent (24.5 per cent for 1920 to 1923 inclusive) of the treated patients developed malaise and slight elevations of temperature. Approximately 10 per cent (9.8 per cent for the years 1920 to 1923 inclusive) developed a generalized urticarial-like eruption or localized erythematous wheal-like lesions at the sites of injections, probably due to sensitization by foreign protein. The gener-

alized rash proved extremely disagreeable and was accompanied by high temperature (102°–105°) in 0.2 per cent of the cases treated. Its usual time of appearance was between the 3d and 10th days of treatment, in some cases persisting as long as 5 days, the average duration being 36 hours. Its occurrence never prevented continuance of treatment.

Three cases of so-called "treatment paralysis" have occurred since our last report. One, in 1922, consisted of a transient weakness of the lower extremities in an adult white male, coming on the first day after completion of an 11-day treatment. It lasted 15 days and was treated by massage, hot baths, and bitter stomachics. Another case developed in a white male, 35 years of age, involving the facial muscles and the upper right extremities on the 8th day of treatment. Its duration was 10 weeks. Antirabic treatment was discontinued, and not again renewed.

Another case, in 1928 in an adult male, 49 years of age, terminated fatally, the immediate cause of death being ascending infection of the urinary tract after paresis of the lower extremities. Symptoms appeared after 5 injections. The offending animal did not have rabies. In addition to these authentic cases, it is possible that other slight and transient neuro-motor disturbances occurred, their nonrecognition being readily understood considering the type of patients treated by us.

We have had 5 deaths (non-protection) following complete treatment. The details of one (1919 series) is given in a previous report.[1]

The fatality in the 1921 series occurred in a negro, male (L. J.) 56 years of age, 44 days after completion of treatment, following slight injury to the hand by a rabid dog. In the 1928 series the first case of non-protection occurred in a negro child (D. L.) 10 years of age, symptoms developing 2 months after completion of treatment. The second, a man 44 years of age (E. S.), developed 2 days after completion of treatment. The third case occurred in a boy 14 years of age (T. G.), symptoms coming on 7 weeks after completion of treatment for bite on the hand by a rabid dog.

SUMMARY

There are reported 5,125 prophylactic antirabic vaccinations by a modified Harris method covering a period of 14 years. Of these, 2,380 followed injuries by proven rabid animals. Three cases of treatment paralysis, one terminating fatally, and 5 cases of non-protection after complete treatment occurred in the series.

Iodized Salt

WILLIAM C. GEAGLEY

State Analyst, Chemical Laboratories, Department of Agriculture, State of Michigan, Lansing, Mich.

SINCE the prevalence of simple goiter in Michigan and its relation to iodine deficiency was outlined in a preliminary report by the Michigan Department of Health,[1] increasing importance has been attached to a universal medium for correcting this iodine deficiency. Of all the means suggested the most effective and generally accepted appears to be iodized salt, for obvious reasons.

The Michigan salt manufacturers were, I believe, the first group to undertake supplying iodine in the form of iodized salt, giving this important element to the people of this and other states at no additional cost.

The general adoption of this procedure in coöperation with the medical profession led to a preliminary survey and examination of the many different brands of iodized salt appearing on the market, with chemical analyses to determine the iodine content. The findings showed a marked variation in iodine content which did not appear warranted, and lessened the effectiveness of iodized salt for the purpose intended.

A coöperative study of the manufacturing methods and conditions under which iodized salt was produced was undertaken for the purpose of determining whether this variation could be eliminated and a uniform product be produced. As a result, a number of outstanding features bearing directly on the problem were observed which, if taken into consideration, would be of material assistance in producing a uniform product.

Two iodine compounds, sodium and potassium iodide, are used generally in the manufacture of iodized salt in Michigan. Claims were made by some that sodium iodide possessed a distinct advantage over the potassium salt, because of a slight difference in physiological properties. However, there were points in favor of the use of one salt or the other for physical or manufacturing reasons. The majority of manufacturers were persuaded to use the sodium salt because of its apparent advantages. Many authorities maintain that in an iodized salt prepared by using potassium iodide the percentage of po-

tassium iodide to salt is so small that when the mixture goes into solution in the digestive system there is such a large excess of sodium over potassium that the effect of potassium is negligible. In other words, if the physiological action of sodium is desirable there is such an excess of it in the salt that it more than counteracts the slight trace of potassium present in potassium iodized salt. As sodium iodide takes up moisture more freely, decomposing, discoloring and freeing iodine in the process, it is not so well suited to the preparation of iodized salt as potassium iodide.

There have been a number of attempts made and, I believe, successfully, to use organic iodides in the preparation of iodized salt. In Switzerland a number of organic iodides have been used quite successfully, and they are less likely to undergo decomposition, thereby possessing some advantage over the inorganic products. The cost, however, is greater and would probably have some bearing on their use. In the last few years W. L. Chandler of the Department of Bacteriology, Michigan State College, has developed a form of organic iodine which is claimed to have advantages over the inorganic products. Whether the use of this form of iodine in iodized salt will be advantageous in so far as the goitrous condition in Michigan is concerned remains to be determined.

The net results of the joint survey pointed out the necessity for a standardized method for mixing iodine and a uniform control procedure.

RECOMMENDED METHOD OF MIXING

Pulverize potassium iodide. Weigh accurately—not measure—2 lb. 2½ oz. of the ground iodide to every 97 lb. 12½ oz. of calcium phosphate.* Mix in a batch mixer for at least 5 minutes. Next grind the mixture to pass a 100-mesh sieve, or finer, and mix again in the batch mixer for at least 20 minutes. The actual iodine content should be checked at this point by analysis.

Weigh accurately 1 pound of this stock mixture for every 99 lb. of dried salt and mix in a batch mixer for sufficient time to give a uniform product as determined by analysis. Each type of mixer will probably have a different time requirement. Ten minutes should give a uniform product with the average mixer.†

Due to the small quantity of iodine as compared to the large bulk of salt, the batch mixer is less liable to give decided variations in uniformity of product than is the continuous mixer. When dealing with a substance as potent as iodine, extreme care should be taken to avoid an overdose as well as to assure the consumer of the presence of iodine.

---

* Because the specific gravity of calcium phosphate is more nearly the same as salt, it lends itself to a better mixture than do most other drying agents. It also has some value as a mineral dietary adjunct for stock.

† Some manufacturers are using an extra mixing at this point. As an added assurance of obtaining a uniform product, the iodide-phosphate mixture is first mixed with a portion of the salt and later the remainder of the salt is added.

CONTROL

Accurate control is very essential because the percentage of iodine recommended is based upon reliable statistics. It is therefore essential that iodized salt adhere closely to this figure. It is of prime importance that the original iodide and dryer mixture be carefully analyzed for uniformity of iodine content. A sufficient number of samples of the finished product should be taken from each batch, or every hour's run, and the actual iodine content determined.

DETERMINATION OF IODINE IN IODIZED SALT

There are several recognized methods for the determination of iodine in the presence of chlorides. Most of them are either not applicable or are too unwieldy to be feasible in the case of iodized salt. The following method was worked out by the writer and found to be both fast and accurate: *

METHOD

Reagents:

1. Syrupy phosphoric acid. U.S.P.
2. Carbon disulphide c.p. This must be water clear and if not should be redistilled.
3. Hydrogen peroxide. U.S.P. Preserve in a cool, dark place.
4. Standard iodide solution is made by dissolving 0.2214 gm. of potassium in a liter of distilled water. It is not necessary to use salt and dryer in connection with this standard solution. Five c.c. of this solution represent 5 gm. of iodized salt containing 0.0221 per cent potassium iodide.† Preserve in a cool, dark place or make up fresh.

Weigh out 5 gm. of the sample. Dissolve in 25 c.c. of water in a separatory funnel.

Prepare at the same time two standards using 4.5 c.c. and 5.5 c.c. of the standard iodide solution. From this point, proceed with both the sample and standards as follows:

Add 5 c.c. of phosphoric acid. Pipette exactly 10 c.c. of carbon disulphide into the mixtures. Add 20 c.c. of hydrogen peroxide and rotate each for 5 minutes. Draw off portions of the lower disulphide layer through a pledget of absorbent cotton into test tubes of equal diameter, ⅜ or ½ inch preferably. Stopper tubes securely and compare the color of the sample with that of the two controls.

These controls represent a 10 per cent variation of iodine content. The sample should fall within the range of the two. If it does not, further mixing or adjusting of the batch will be necessary. A number of samples can be run at the same time, using the same two controls.

After iodized salt had been manufactured and marketed for a considerable time the director of the Bureau of Foods and Standards of the Michigan Department of Agriculture caused a number of representative samples of the different brands as offered for sale in the regular trade channels to be collected and submitted to the laboratories for determination of the iodine content (see Table I).

* This method may be used as an accurate, quantitative laboratory procedure by the use of a Duboscq type of colorimeter, in which case one control made with 5 c.c. of the standard iodide solution is used as the standard of comparison.

† This is recommended by the Michigan Department of Health and represents the iodine equivalent of 0.02 per cent of sodium iodide calculated to potassium iodide.

It will be noted that there is a deficiency in every instance except one.

The question naturally arises as to whether the deficiencies are due to a loss of iodine after manufacturing or to poor mixing. It has been

demonstrated a number of times that with carefully controlled manufacturing processes iodine may be incorporated in a fairly uniform manner throughout the mix. There are undoubtedly losses due to exposure and other conditions to which the manufactured product is subjected.

The laboratories have examined for iodine content many specimens of iodized stock salt in which the department has been interested because of its use and value for alleviating conditions found in newborn colts, calves, pigs, lambs, etc. After storing specimens under a number of different conditions it was readily demonstrated that many factors were influential in liberating iodine from salt.

This question was studied quite thoroughly under controlled conditions by Arnold H. Johnson and V. L. Harrington of the Chemistry Department of the Montana Agricultural Experiment Station. Their findings are quoted:

Iodized salts stored in atmospheres of relative humidities of 50 per cent lose smaller quantities of their iodine than salts stored under similar conditions at other humidities.

Iodized salts rendered alkaline by the addition of $NaHCO_3$ lose practically none of their iodine during storage, while neutral salts or salts rendered acid lose appreciable quantities.

Salts iodized with KIO_3 lose none of their iodine when stored for extended periods.

Exposure of iodized salts to sunlight effects a loss of iodine from neutral or acid salts; only a slight loss from salt rendered alkaline; and practically no loss from salts iodized with KIO_3.

Exposure to heat alone effects losses of iodine from acid, neutral, and alkaline iodized salts, and from salt iodized with KIO_3, in precisely the same order as did exposure to sunlight.

Exposure to light and heat simultaneously effects greater losses of iodine from salts of neutral or acid reaction than exposure to light alone or heat alone. In the case of iodized salts of alkaline reaction the losses of iodine are again insignificant or negligible, even though the salts are exposed to light and heat simultaneously.

The quantity of iodine liberated from a neutral salt iodized with KI appears to depend on the quantity of KI present.

Typhoid Fever in a Rural Village of Porto Rico Due to a Surface Well

E. GARRIDO MORALES, M. D., DR. P. H.

Epidemiologist, Insular Department of Health, San Juan, P. R.

IN a previous report[1] the writer discussed the typhoid fever problem in Porto Rico in general, pointing out some of the outstanding epidemiological features of the disease as observed in the island. The present paper is a discussion of an intensive study made of an outbreak which developed in Judea, a village located in the municipality of Utuado, following the recent hurricane.

The investigation of the outbreak included:

An epidemiological study of all the typhoid fever cases reported or located in the village

A special survey of the entire population of the village to obtain some knowledge of its composition, as well as the sources of water and food supplies and the sanitary status of the people

A special investigation to determine the sources of infection of the outbreak, including a bacteriological examination of water from a well suspected to have originated the outbreak

The municipality of Utuado, one of the 77 into which the island of Porto Rico is divided, is located in the central and western part. It has a town with 4,093 inhabitants, the remainder of the population totalling 34,523 persons, distributed in 23 rural districts.

Arenas, one of the rural districts, with an estimated population of 2,075 persons in 1928, has a village where slightly over 600 people live. Because of the proximity of this village to the town of Utuado, the water supply of the latter was extended to it. Previous to the recent hurricane, the people had 3 main sources of water: a spring located at the bottom of a hill; a surface well situated close to a creek which crosses the village; and the public water supply from the town of Utuado. Since the aqueduct was damaged by the cyclone, water from this source was not available during 2 weeks following it. Although the town has a sewerage system, there are no sewer connections in the village. The disposal of excreta is in latrines, some of very poor construction.

No accurate records of the occurrence of typhoid fever in the village in previous years were available, but from the information col-

TABLE I

DATES OF ONSET

Week Ending	Number of Cases with Onset	Number of Patients Taken to Bed

Oct. 13	6	3
Oct. 20	7	7
Oct. 27	10	10
Nov. 3	6	8
Nov. 10	3	5
Nov. 17	–	1
Nov. 24	1	1
Total	42	42

lected in a house to house canvass, it appears that these people have been comparatively free from the disease in recent years. A history of a probable attack of typhoid fever, during the last 5 years, was obtained from only 6 persons in the village. Two of these died and none was confirmed by bacteriological examination. Forty-six cases were reported from the village during the present outbreak, 4 of which were eliminated because they were not typhoid fever. All others were confirmed bacteriologically and 4 terminated in death.

The dates of the onset of first symptoms and the dates on which the patients were confined to bed were as shown in Table I.

The chronology of the outbreak suggests massive infection with its maximum intensity in the latter part of September.

The cyclone occurred on the 13th of the same month, and on this date that group of people in the village who had used water from the public water supply of Utuado, because of the damage to the aqueduct,

TABLE II

AGE AND SEX OF THE CASES

	Males		Females		Both Sexes	
Age Groups	No.	Per Cent	No.	Per Cent	No.	Per Cent

began using water from a surface well located nearby. Table II gives age and sex of cases investigated.

Males under 20 apparently furnished a disproportionately large percentage of the cases, though the numbers are too small to be significant.

The age groupings and sex of the cases and those living in the village who were not attacked are presented in Table III.

TABLE III

AGE AND SEX OF RESIDENTS AND CASES

Age Groups	Males				Females				Both Sexes			
	Persons		Cases		Persons		Cases		Persons		Cases	
	No.	Per Cent	No.	Per Cent	No.	Per Cent	No.	Per Cent	No.	Per Cent	No.	Per Cent
Under 20	150	52.26	12	63.16	200	57.47	12	52.17	350	55.12	24	57.14
Over 20	137	47.74	7	36.84	148	42.53	11	47.83	285	44.88	18	42.86
Total.....	287	100.00	19	100.00	348	100.00	23	100.00	635	100.00	42	100.00

The number of persons of both sexes under 20 in the village exceeded those over 20 years of age. The lengths of residence of the patients and controls were as given in Table IV.

TABLE IV

LENGTH OF RESIDENCE OF CASES AND CONTROLS

Length of Residence	Cases		Controls	
	No.	Per Cent	No.	Per Cent
1 year or less.....	12	28.57	181	28.50
2 years.....	12	28.57	135	21.26
3 years.....	9	21.43	181	28.50
4 years.....	8	19.05	92	14.49
5 or more years.....	1	2.38	46	7.24
Total.....	42	100.00	635	99.99

Although 28 per cent of the cases occurred among persons who had resided in the village less than 1 year, and over 95 per cent in those who had resided there less than 5 years, this was also true of those not attacked; so the disease was not excessively prevalent among newcomers.

Whether any of the patients or the control group had been absent from home during 30 days previous to the outbreak was determined, with the results shown in Table V.

TABLE V

Total	42	99.99	635	100.00	42	100.00	635	100.00

As one would expect to find in any rural district of Porto Rico, the economic and sanitary status of the people was rather low. The epidemic, however, was not confined to those of any economic or sanitary status, the cases being distributed in proportion to the number of persons in each group.

Whether or not the persons or patients had eaten ice cream or had meals away from home during 30 days previous to the onset of the outbreak was determined, with the results shown in Table VII.

TABLE VII

A	1	Sept. 23	5	Oct. 1	28	Oct. 23	34	Oct. 26
B	4	Sept. 28	17	Oct. 14	18	Oct. 15		
C	8	Oct. 4	9	Oct. 4				
D	10	Oct. 9	23	Oct. 20				
E	11	Oct. 10	42	Oct. 10				
F	12	Oct. 11	25	Oct. 21	40	Nov. 1		
G	14	Oct. 13	31	Oct. 25				
H	22	Oct. 19	24	Oct. 21				
I	32	Oct. 25	41	Nov. 4				

In families C, E, and H, contact infection was impossible. In families D, F, G, and I, infection through contact was possible but not probable, as the time between primary and secondary cases was presumably too short. The dates of onset of primary and secondary cases in those instances where infection could have been contracted through visiting were as presented in Table XI.

TABLE XI

INTERVALS BETWEEN PRIMARY AND SECONDARY CASES

Primary Case		Secondary Case		Interval in Days between Primary and Secondary Cases
Case No.	Onset	Case No.	Onset	
8	Oct. 4	39	Oct. 31	27
9	Oct. 4	20	Oct. 15	11
24	Oct. 21	37	Oct. 29	8
14	Oct. 13	30	Oct. 24	11
19	Oct. 15	29	Oct. 23	8
9	Oct. 4	13	Oct. 14	8
32	Oct. 25	33	Oct. 26	1

In case number 33 contact infection can definitely be excluded. In the rest, except case 39, the incubation period was perhaps too short for contact infection, unless a heavy dose of germs was ingested. This might have happened through multiplication of typhoid bacilli in a

contaminated food partaken by any of these patients. All, however, denied having eaten anything during their visits to other cases.

It has been definitely established that when typhoid fever is introduced into a community where the methods of excreta disposal are faulty and where the care and precautions at the bedside of patients are obviously defective, infection through contact always plays a part in the dissemination of the disease. In view of the above facts it is presumed that personal contact, both direct and indirect—in the present instance because of the unusual conditions prevailing in the village after the hurricane—although not the major factor was an agent of some importance in the spread of the outbreak.

The sources of water used by the patients and controls during 30 days previous to the outbreak are given in Table XII.

TABLE XII

ATTACK RATE BY SOURCES OF WATER SUPPLY

Source of Water	Persons in Village Using Each Source	Cases Using Each Source	Attack Rate per 1,000 among Each Group
Aqueduct and suspected well	226	28	123.89
Spring alone	139	1	7.19
Aqueduct and spring	46	2	43.48
Aqueduct, spring and suspected well	54	5	92.59
Spring and suspected well	30	5	166.67
Aqueduct, well, other sources	19	1	52.63
Spring, other sources	17	—	—
Aqueduct, other sources	49	—	—
Aqueduct, spring, other sources	22	—	—
Various sources	33	—	—
All sources	635	42	66.14
Well water	329	39	118.54
Not well water	306	3	0.98
Both	635	42	66.14

The risk of attack among those who used well water was 118.54 per 1,000, while the risk of attack among the group who did not was 0.98 per 1,000. Stating it in a different way, 329 people who used well water, or 51.81 per cent of the total population, contributed 39 cases or 92.86 per cent of the total number, while 306 people who did not use well water, or 48.19 per cent of the total, furnished only 3 cases, or 7.14 per cent of the total number recorded.

On the basis of probability, in a normal group, the expected number of cases among the people who did not use well water was 20, and only 3 occurred, while the expected number in the group who used it was 21, and 39 occurred. The probability that such a distribution was due to chance alone is 1 in 10,000. Two out of the 3 cases which occurred among those who did not use the well water gave a history of

direct intimate personal contact with a previous case and were regarded as probable contact patients.

CONTAMINATION OF THE WELL

The investigation conducted to locate the possible sources from which the well was contaminated revealed that on August 14 a young woman was taken ill with typhoid fever in the village. This patient had clinical typhoid, and her Widal on August 29 was positive. Her home was in close proximity to the well. The excreta from the patient was disposed of without the addition of any disinfectant, in a poorly constructed latrine about 6 yards from the well. The opportunities for its contamination with the privy contents were ample, especially after the heavy rains which accompanied the hurricane.

The bacteriological examination of a sample from the well, obtained on October 26, gave the following results:

Bacteria per c.c. innumerable
Fermentation in 10 c.c. (48 hours) 80 per cent
B. coli in 10 c.c. present
B. coli in 1 c.c. present
B. coli in 0.1 c.c. present

SUMMARY

The explosive character of an outbreak of typhoid fever following the recent hurricane among the people living in Judea, a semi-rural village of the municipality of Utuado, P. R., together with the high incidence rate among the population in the village, immediately suggested a vehicle in use by a large proportion of the people, as the chief factor of causation. Water from the public supply of Utuado was eliminated because the people in that town escaped. Only 4 cases occurred in that town with a population of over 4,000, 90 per cent of whom used the public water supply. The infection in 4 cases which occurred in a single family was traced to probable contact with a case in Judea, through a cook who nursed her sister, a typhoid patient in the village, and prepared all the food for this family in the town. Milk, ice cream, and other foods were excluded as contributing to the spread of the outbreak.

Water from a surface well used by about one half of the people in the village after the hurricane was regarded with suspicion. The result of the epidemiological investigation confirmed the suspicion and this water was regarded as the major factor in the causation of the outbreak. Although the people who used water from this well formed only 51 per cent of the total population of the village, this group contributed 92 per cent of the cases. Infection in 2 out of only 3 cases who did not use this water supply was definitely attributed to contact

with previous cases of the disease, leaving only 1 case in the group who did use well water whose origin was not determined.

The evidence seems to warrant the conclusion that water from the surface well was the major factor in the causation of typhoid fever during the recent outbreak in the village of Judea, and that contact infection acted as a secondary contributing factor.

Spanish Law on Maternity Insurance

COMPULSORY maternity insurance was established in Spain by a law passed March 22, 1929, the provisions of which differ considerably from those of the provisional decree on the same subject of August 21, 1923. The purpose of the law, like that of the decree, is to give effect to the international draft convention on the protection of maternity ratified by Spain in 1922.

According to the new law all wage earning women between the ages of 16 and 50, except those in domestic service, must carry maternity insurance. Each insured woman will pay 7.50 pesetas (about $1.50) annually, and her employer will pay an equal amount. The State is to contribute to the insurance fund 50 pesetas for each confinement and other unspecified amounts for nursing benefits.

Every insured woman is entitled to medical aid and medicines during pregnancy and confinement and to a weekly cash benefit for the 6 weeks following her confinement, during which she is required to stay away from work. Her place must be kept for her by the employer for a certain length of time. Upon presenting a physician's certificate of pregnancy, an insured woman has the right to stay away from work for the 6 weeks before her confinement, and a benefit is paid during that time also.

The amounts to be paid as benefits will be set in subsequent regulations.

The law also provides for the establishment of a Maternity and Infancy Fund (*Fondo Maternal e Infantil*) to be used for establishing new maternity and infancy health centers and for aiding those already in existence. The resources of the Fund will consist of a certain percentage of the premiums paid by the insured women and of donations from public and private sources.

When the available resources permit, a cash benefit may be paid beyond the prescribed period if the mother is ill as a result of childbirth, or if the mother loses her employment through such illness, or if the child is ill.

The general administration of the law will be in the hands of the National Provident Institute, which administers also the law on old-age pensions. To see that the women are given the medical aid, the cash benefit, and the rest period prescribed by law, local maternity insurance organizations will be established in certain cities. In other places local administration of the law will be carried on by certain approved mutual aid societies, public child welfare boards, public boards of education, or public health boards, in which the insurance organizations, the workers, and their employers must be represented.

The law prescribes fines for employers and employees who fail to comply with it.—*Gaceta de Madrid*, Mar. 24, 1929, pp. 2202–2206.

Nativity and Disease Susceptibility

GEORGE B. L. ARNER, PH. D.

Pennsylvania Bureau of Vital Statistics, Harrisburg, Pa.

MORTALITY rates from diseases of advanced life in the United States are uniformly higher among the foreign born than among the native born. Furthermore, the mortality rates from these causes are much higher among the Irish and German born than among those born in Italy, Poland and the former Austro-Hungarian empire. In view of these surface indications investigators have frequently assumed that the foreign nationals in the United States, and particularly the Irish and Germans, were particularly subject to whatever disease happened to be in question.

In making these statements such investigators have lost sight of the rather obvious fact that the foreign born are on the average older than the native born. The native born population is regularly distributed with regard to age with the largest number in the first age group and numbers diminishing steadily with advancing years. The foreign born population on the other hand is small in the age group under 5 years, since the children of the foreign born are themselves usually native born. In the population of Pennsylvania in 1920 the median age of the native born whites was 21.4 years, with quartiles at 9.3 and 39 0, while in the foreign born population the median age was 38.4 years, with quartiles at 29.4 and 49.8.

In 1927 there were, according to the state tabulation, 9,283 deaths in Pennsylvania from cancer and 20,771 from heart disease, giving crude death rates for these causes of 95.4 and 214.0 per 100,000 population. The median age at death from cancer was 62.2 years and from heart disease 66.3 years. The crude death rates by nativity for cancer were, native born 81.2 and foreign born 180.2, and for heart disease, native born 184.0 and foreign born 382.3 per 100,000 population. But by computing age specific death rates, multiplying these rates by the estimated native and foreign population at each age group and adding the products, it is found that on the basis of age alone the expected number of cancer deaths by nativity would be 7,096 native born and 2,187 foreign born. The actual figures were 6,843 native born, 2,343 foreign born and 97 unspecified. For heart disease the expected distribution of deaths was native 16,024 and

foreign 4,747 as compared with an actual distribution of 15,509 native, 4,970 foreign and 292 unspecified. In view of the difficulty of making satisfactory population estimates by age, 7 years after an enumeration, these results are remarkably close, and show that age for age there is little difference in the mortality from cancer and heart disease as between the native born and the foreign born.

Roughly estimating the numbers of foreign born in Pennsylvania by country of birth, the crude death rates for each of the principal national groups from cancer and heart disease were as shown in Table I.

TABLE I

Country of Birth	Rates per 100,000 Population in Each Nationality	
	Cancer	Heart Disease
United States	81	184
Ireland	428	1,127
Germany	480	1,120
Italy	105	195
Austria-Hungary	106	201
Poland	111	242
Russia	127	290
All Other	217	393

It will be noted that the death rates for the Irish and Germans are extremely high, while the natives of Italy, Austria-Hungary, Poland and Russia have rates little above those of the native born population. In the group of "all other countries" the largest numbers are from Great Britain, the Scandinavian countries and Greece.

The U. S. Census does not give the age distribution of the separate national groups of the foreign born population; so it is impossible to calculate directly the expected mortality of these groups on the basis of age. But it is well known that the waves of Irish and German immigration came early, while the Italian, Austro-Hungarian, Polish and Russian immigrations followed after the influx of the Irish and Germans began to decline. In the United States as a whole the populations of Irish and German birth were greater in 1890 than in any other census year. That was nearly 40 years ago, and the survivors of that early immigration must now be well advanced in age. On the other hand, in spite of the practical suspension of immigration during the World War, the populations of Italian, Austro-Hungarian, Polish and Russian birth were larger in 1920 than in any previous census year. It is certain therefore that the median ages of the living Irish and German born populations are far higher than the median ages of those born in the other countries named. The cancer and heart disease death rates of the Irish and German born correspond with the age specific death rates in the entire population for the group between

the ages of 60 and 69 years. Considering the time which has elapsed since the peak of the immigration from these countries it is entirely possible that the median age of the Irish and German born in Pennsylvania is somewhere between 60 and 70 years. The death rates from these causes among the other national groups mentioned correspond with the age specific death rates of the group between 40 and 49 years. Since the median age of the foreign born in Pennsylvania was 38.4 years in 1920, and since the foreign born in Pennsylvania were largely of this later immigration, and further since there has been very little immigration since 1920, it is very probable that the median age of the natives of these countries in Pennsylvania was between 40 and 49 years in 1927.

While the numbers of living persons by country of birth and age are not available, the deaths by nativity and age give some indication of the relative ages of the national groups in which the deaths occur. Table II gives for both cancer and heart disease the median age at death and first and third quartiles for all deaths from these causes in Pennsylvania in 1927 and for each of the indicated national groups.

The differences in age classification between the Irish and Germans and the other foreign born are very striking. In cancer, the median age at death of the German born is 13 years higher than for those born in Austria-Hungary, and in heart disease the difference is still greater. Since there are comparatively few deaths from either of these diseases under the age of 45, which is the lowest age on the table for a first quartile, the differences in age groupings between the

TABLE II

COMPARATIVE AGES AT DEATH FROM CANCER AND HEART DISEASE BY COUNTRY OF BIRTH
Pennsylvania, 1927

Country of Birth	Cancer			Heart Disease		
	1st Quartile	Median	3d Quartile	1st Quartile	Median	3d Quartile
	Years	Years	Years	Years	Years	Years
Total	51.8	62.2	71.1	53.5	66.3	75.7
United States	52.0	62.7	71.7	52.8	66.6	75.8
Foreign	51.6	61.1	69.3	55.1	65.4	75.4
Unspecified	48.4	58.0	68.0	52.6	64.6	74.1
Ireland	55.7	63.7	73.7	61.1	69.9	78.5
Germany	60.5	67.5	75.0	64.9	73.9	80.3
Italy	46.6	57.5	66.3	50.1	60.4	68.1
Austria-Hungary	46.9	54.6	62.5	47.2	56.3	65.1
Poland	45.7	52.7	60.3	45.7	54.2	62.3
Russia	48.9	57.2	62.6	50.3	59.5	67.4
Other Countries	53.7	62.6	70.7	58.9	69.0	77.0

native born and the total foreign born are not reflected in this table. The median ages at death from these diseases are even slightly lower for the foreign born than for the native born. The differences as between national groups are just what should be expected at the presumed relative age classifications of these groups.

While we should like to be able to confirm our conclusions by an accurate standardization of mortality rates as between the different groups of the foreign born, all of these figures point to the conclusion that there is no difference in rates from cancer and heart disease which cannot be accounted for by differences in the age composition of these national groups. These diseases, and perhaps all diseases of advanced life, appear to know no distinction between native and foreign, German or Italian, Irish or Hungarian. Any assertion of a greater or less susceptibility to disease in any group of the population needs to be supported by something more than crude rates.

The Woman Physician

NO group can so effectively, so humanly, meet the growing demand for health direction as the woman physician. I believe she is naturally better equipped to specialize in this line than the man of our profession. It has always been the woman who has cared for the health of her family; it was always the woman in the early communities, before the days of the doctor and nurse, who served her neighbors with natural, simple remedies, and it has been my observation that women have more interest in the constructive things of life than in the destructive. Perhaps the basis of this is biological. At any rate you and I have these desirable and necessary qualities of our sex in addition to our training as physicians to apply to furthering this new interest in health. The combination should make us lead out in this movement. Whether we become health specialists, or include the health practice with our present practice, there is still one more thing we may do, and that is, never let an opportunity pass of making clear the difference between the strictly medical, the protective and the preventive examinations on the one hand and the health examination on the other; and also by never letting a chance go by to stress the fact that a health examination automatically necessitates a health prescription leading to a specific goal of health positive. When we can get both the lay and the professional to come to a like understanding on these points, then health positive will have become a fact, a recognizable and accepted asset of human welfare. Lenna L. Meanes, M.D., "The Health Examination and its Goal"—An address read before the New York City Medical Woman's Association at the New York Academy of Medicine, *Med. Woman's J.*, 36, 7: 169 (July), 1929.

Two Milk-borne Septic Sore Throat Epidemics

PAUL B. BROOKS, M. D., FELLOW A. P. H. A.

Deputy State Health Commissioner, Albany, N. Y.

TWO milk-borne epidemics of septic sore throat developed in New York State between February 1 and April 1, 1929, under circumstances which in several respects were similar. Both were explosive in character and occurred in rural villages—in Wayland, Steuben County, with a population of 1,767, and Savannah, Wayne County, with a population of 612; each was traced to raw milk from a herd in which a case of mastitis was discovered; and there were cases of sore throat on both farms, in one instance previous to the discovery of the mastitis, and in the other subsequent to its discovery.

THE WAYLAND OUTBREAK

There were 141 known cases at Wayland, nearly all developing February 16 and 17, with the last on the 18th. All those investigated had used raw milk from the G. H. dairy, which sells approximately 128 quarts of raw milk daily to 120 families, out of a total for the village of approximately 700 quarts.

About February 1 there was a case of sore throat in the G. H. family, and on the 12th the principal milker developed the condition, apparently continuing to milk. There were no cases among patrons in the interval. On February 16 and 17, when most of the victims were having their onsets, Mr. and Mrs. G. H. developed the disease. On February 14 mastitis, involving one quarter, was discovered in a cow. As nearly as could be determined the milk from this cow was excluded until the 16th, was included on the 16th, 17th and morning of the 18th, and then permanently excluded. Table I gives the chronological relationship.

The epidemic first came to light on February 18 when the proprietor of a local chair factory reported that 40 employees were off duty on account of illness associated with sore throat. This factory obtained 80 pint bottles of milk from the G. H. farm daily, and investigation revealed that all of the employees who were ill had used the milk. In one family 3 persons who had used G. H. milk were ill, while 1 who used no milk, and a baby receiving only boiled milk,

TABLE I

WAYLAND

Feb. 1	2–11 inclusive	12	13	14	15	16	17	18
Case on G. H. farm		Onset of case of principal milker		Mastitis discovered		*Cases developed* among patrons; most of them on 16th and 17th		
				Milk from cow with mastitis excluded		*Milk included* 16th, 17th and morning of 18th		Definitely excluded on the 18th

escaped. In another family 2 children who received only boiled milk escaped, while 2 adults using G. H. milk raw were ill. In 2 cases it was determined with practical certainty that the milk responsible for the infection was consumed on the afternoon and evening of Saturday, February 16, and that the first symptoms of illness appeared early the following morning. Peritonsillar abscesses and adenitis complicated several cases, and death occurred in 1 case complicated by facial erysipelas.

The county laboratory on February 20 examined a milk sample from the infected quarter of the cow with mastitis. It was " thick and yellow and contained a great number of pus cells " and " short chain " streptococci. Tests were not made for hemolysis. Subsequently the state laboratory received " about 3 c.c. of slightly brownish thin milk " from the infected quarter, and, although there were many pus cells and bacteria, no hemolytic streptococci were found. The predominating organism was a streptococcus producing methemoglobin. At the same time throat cultures from a number of convalescent patients including the proprietor of the G. H. dairy were examined and found to contain hemolytic streptococci, believed to be of the type usually associated with human infections of this character.

THE SAVANNAH OUTBREAK

At Savannah there were approximately 75 cases, between March 10 and 18, most of them between the 10th and 13th, the " peak " occurring on the 12th, and the last cases, except 2 contact infections, developing on the 18th. All of those investigated had used raw milk from the W. H. dairy. The proprietor is the only dealer—aside from a few people selling surplus milk from one cow—and distributes between 100 and 200 quarts of raw milk daily. Three members of the W. H. household were ill, but not until March 12. No evidence could be obtained of the occurrence of sore throat on the farm previously.

One cow in the herd sustained an injury to one teat about March 2, which prevented the use of the milking machine, but the other three

quarters were milked by hand. A veterinarian examined the cow on the 6th and stated that at that time he found no evidence of mastitis. Swelling was said to have been discovered first on March 13, but milk from the unaffected three quarters appears to have been included until the 15th, when the dairy was visited by representatives of the State Department of Health, and the cow segregated. At that time the animal was obviously ill.

The epidemiological evidence connecting the W. H. milk with the epidemic was conclusive, as in Wayland. In one family a child who received the milk at school was ill, while no cases occurred among other members of the family who used other milk only. In another family 2 adults who used the W. H. milk on cereal were ill, while 2 children who had no milk escaped. Several cases were complicated by abscesses and adenitis, and there was 1 death directly or indirectly attributable to the epidemic.

TABLE II

SAVANNAH

Mar. 2	6	7–9	10–11	12	13	14	15	16–18
Cow's teat injured	Cow examined by veterinarian. No evidence of mastitis			*Case developed among patrons* Peak of epidemic onset of 3 cases on farm	Mastitis discovered			
	Milk from injured cow included				*Milk from* affected quarter said to have been excluded		*All milk* excluded	

Dr. Hervey reported the following interesting and significant instance of infection. The veterinarian, who lives in an adjoining village and had used no milk from the W. H. dairy, visited the dairy with representatives of the State Health Department on March 15. In the course of an examination of the cow with mastitis he drew material from the infected quarter, for visual examination, into the palm of one hand; then with this hand he drew milk from an apparently unaffected quarter into the other hand and tasted it "to see if it was salty." Two days later he developed a sore throat. Cultures submitted for laboratory examination were found to contain hemolytic streptococci.

Dr. Breed and members of the staff of the state laboratory isolated these organisms from milk from the affected quarter of the cow with mastitis. Throat cultures submitted to the state laboratory from a number of the patients were also found to contain hemolytic streptococci. This laboratory has reported that the organisms from the milk and from representative cases corresponded as to morphological and

cultural characteristics, and biochemical reactions, and apparently were of the type usually associated with human infections of this character.

RELATION OF MASTITIS TO THE EPIDEMICS

The most interesting question in connection with these outbreaks is the relationship, if any, between the cases of mastitis and the epidemics. At Wayland failure to find hemolytic streptococci in material from the infected udder leaves a " missing link " in the chain of evidence, since the material was not received and examined at the state laboratory until March 11, over 3 weeks after discovery of the mastitis. The possibility of these organisms having been present earlier must be considered. It will be recalled that the infected udder was discovered on the 14th, and the milk excluded until the 16th; it then apparently was included again until the 18th, when it was definitely excluded. All of the cases developed between the 16th and the 18th. If the mastitis was responsible, even in view of the 12-hour incubation period cited in 2 of the cases, the termination of the epidemic on the 18th can only be explained on the assumption that hemolytic streptococci were previously present, but had disappeared or were in very small numbers in the milk which was being included on the 17th and morning of the 18th. Recalling that the principal milker became ill on the 12th and continued to milk, the alternative explanation is that on the 14th or 15th, or both, the milk handled by him was grossly contaminated, probably through coughing or sneezing.

Basing judgment on information now at hand concerning the Savannah epidemic, the evidence incriminating the mastitis is convincing. Hemolytic streptococci, apparently of the same type, were isolated from material from the infected udder and from throat cultures. When the mastitis was discovered on the 13th it was well developed and probably had existed for several days. Allowing a 2-day incubation period, the cases with onsets on the 10th would have received their infections on the 8th and it is not unreasonable to assume that virulent organisms were then being discharged, especially in view of the history of previous injury. The milk from the affected quarter was excluded from the 13th but that from the other three quarters included. The opportunity for contamination by the milker was undoubtedly sufficient to account for the comparatively few cases which developed between the 15th and 18th.

NOTE: This report is based upon data furnished by John A. Conway, M.D., District State Health Officer, and A. E. Richmond, M.D., local health officer, who investigated the Wayland epidemic, C. R. Hervey, M.D., District State Health Officer, W. H. Sweeting, M.D., local health officer, and Robert S. Breed, Ph.D., Consultant in Dairy Sanitation, who investigated the Savannah epidemic, and on preliminary reports from the state laboratory. Both Dr. Breed and the state laboratory are, at the time of writing, engaged in further bacteriological studies.

Training and Personnel*

THE following tables similar to those presented in previous years include the data concerning students registered in schools of public health, and the public health degrees granted in the calendar year 1928.

The central office of the Association has collected certain data in an attempt to determine what happens to students after they are graduated from schools of public health. Through the courtesy of the Executive Secretary the information obtained is presented herewith. Twenty schools were questioned but only 15 were able to give sufficient information for tabulation. From 1921 to 1925 inclusive these 15 schools granted degrees to 56 women and 282 men.

Of the 338 graduates listed, information regarding 133 was missing or was insufficient to tabulate. The subsequent careers of the remaining 205 graduates are listed in Table IV.

Although the classification of occupations is general, the data are of some interest. It will be noted that 133 individuals out of 338 have practically disappeared from the field of public health. Data regarding scholarship or fellowship grants are not available from all schools. The reports indicate that at least 150 of these students held scholarships or fellowships. An appreciable number of the individuals holding fellowships were foreign students.

The following tentative statement of desirable minimum training requirements for all public health workers expresses the opinion of the committee. It is here presented for further consideration, and by vote of the committee each section representative has been requested to submit the statement to his section with the request that said section prepare a statement of the desirable further training requirements for the field of public health work in question.

MINIMUM BASIC TRAINING FOR THOSE WHO ANTICIPATE ENTERING THE PUBLIC HEALTH PROFESSION NO MATTER WHAT THE SPECIALTY MAY BE:

I. General College Training

The general college training or its equivalent should include courses in general inorganic and organic chemistry, physics, zoölogy (general biology), and, if possible, also psychology, sociology and civics.

---

* Report of the Committee presented at a Dinner Session of the American Public Health Association at the Fifty-seventh Annual Meeting, Chicago, Ill., October 17, 1928.

II. Instruction Directly Related to Public Health

No suggestion is here made as to specific courses, which may be combined or subdivided in various ways at various institutions. The characteristic viewpoints of these 5 fields should, however, be represented.

1. *Physiology and Personal Hygiene*—The structure and functions of the human body and the various factors essential in building up and maintaining it in a sound, vigorous and harmonious state. Its relation to air, sunlight, water, food, shelter, exercise, rest, poisons and injury should be given due consideration. The prevention and correction of defects, periodic health examinations and mental hygiene should have their proper emphasis.

2. *Bacteriology and its Application to Public Health*—It is desirable that some reference to both sanitary and medical bacteriology be included. Data should somewhere be presented as to the nature, source and methods of the transmission of communicable diseases and their control.

3. *Public Health Engineering*—The engineer's angle of approach to the problems of water supply, waste disposal, air conditioning and milk sanitation.

4. *Vital Statistics and Epidemiology*—Fundamentals of sound elementary statistical procedures and the statistical methods employed in studying the incidence of epidemic and other diseases.

5. *Community Health Practices and Education*—The social and psychological problems involved in health organization, sound civic administration and the formation of public opinion.

All lecture courses should be supplemented by appropriate laboratory or field work.

The foregoing fundamental training should prove to be an excellent foundation upon which specialization in the various fields of public health may be built.

Training indicated under I may be secured in any college.

Training indicated under II may be secured in many colleges.

SUB-COMMITTEES AND SECTION REPRESENTATIVES

In order to strengthen its working efficiency the committee hereby empowers the appointment of sub-committees by the chairman, as occasion arises, for the pursuance of special pieces of work and the committee requests the sections of the Association to appoint section representatives on this committee for 2-year periods instead of 1-year as in the past.

RECOMMENDATIONS

The committee is of the opinion that the accumulation of data amounting to a stock taking of the training and professional status of public health workers in the United States is desirable. It is a necessary step for the committee to formulate definite recommendations for the future training, tenure of office and economic return for public health workers. In line with the report of the special sub-committee which has been studying this problem we believe that:

1. A comprehensive survey should be made of the institutional facilities and procedures now in use in the training of individuals ultimately intending to enter the professional field of public health work. The collection of such material by mail is inadequate and unsafe, since so many of the advantages or objectionable characteristics of the procedures do not appear in second-hand exchange of information by letter writing.

2. A careful and first-hand study should be made concerning the variety of extension courses now carried on by federal, state, and municipal public health

agencies, universities, voluntary agencies, or any of these jointly, in order to acquaint the committee with the progress that has been made in supplementing the professional activities of public health workers by extramural training courses. Many in public health work are of the opinion that such extension courses made available to active workers are more effective developers of initiative and efficiency than the ordinary full-time university courses. Examples have been noted in the literature of the great value of such courses in various cities and universities. A review of such undertakings is likely to be instructive.

3. The present status of salary standards, permanence of tenure, and mode of selection of workers should be reviewed. Here again field investigation is essential, particularly with reference to permanence of tenure and mode of selection of workers, since the political, psychological, and other controlling factors in this situation are, and will continue to be, of great importance in the attempt to raise the general level of professional public health work.

4. A survey should be made of the nature, quantity, and quality of previous training of the public health workers now in active practice.

5. The use and abuse of legislative and civil service restrictions in the selection and dismissal of public health workers are matters of considerable interest. These regulations and restrictions should be carefully reviewed and tabulated, in order to determine their advantage, obsolescence, and danger. The lay public must be educated to the inherent objections or advantages in the present variety of laws and civil service requirements. Some of these requirements are helpful, others harmless,

and still others have proved their usefulness, primarily in affording opportunities for political interference in the appointment and dismissal of public health workers. The committee could perform an exceedingly helpful public duty by analyzing this situation in the country at large, by pointing out the demerits wherever found and ultimately by formulating recommended procedures of legislative and civil service regulation.

6. Considerable discussion arises at every session dealing with the training of public health workers as to whether or not existing medical schools contribute much or little to the instruction in preventive medicine of medical students. The content of, and the allotment of time to, the public health courses in medical schools should be the subject of further study and report.

It is recommended that this committee establish a budget and, with the aid of the administrative office of the Association, seek special funds for the employment of a part-time or full-time worker with sufficient allotment for travel expenses to perform the duties noted above and to report in detail and in writing to the Committee on Training and Personnel on the results of the study.

SALARY STANDARDS

It is the belief of this committee that the report on salary standardization made to the Association in 1922 is now in need of revision in respect to both facts and recommendations. This committee desires to undertake a revision of that report and requests the Association to approve the setting up of a budget for the purpose, the amount of said budget to be determined by the Executive Board and the work to be done in connection with the more extensive study outlined above or as a separate investigation.

Local Immunization and Antivirus

NEWTON W. LARKUM, PH. D.

Michigan Department of Health, Lansing, Mich.

LOCAL immunization by means of antivirus has received relatively little attention in the medical literature of the United States. It would appear that this situation has resulted partly from a lack of faith in the reports printed in foreign journals, and partly to a lack of familiarity with such publications. Consequently it would seem advisable in a public health periodical to review the subject briefly, and to state what appears to be the present status of this method of immunization. Such a discussion must include two quite separate and distinct discoveries—one, local immunization, a conception that since in a given infection a certain tissue is primarily affected, immunization of that tissue should prevent the infection; the other, that a certain substance, "antivirus" (Besredka), contained in filtrates of old broth cultures of bacteria is the principle which can best produce this local immunity. Such antivirus is specific, and when used in the treatment of staphylococcus infections should be prepared at the expense of staphylococci.

The idea of local immunity was originated by Besredka and is fully presented in *Local Immunization.*[1] Every pathogenic bacterium is virulent for a certain tissue according to this author. Thus, the typhoid, paratyphoid and dysentery bacilli and the cholera vibrio primarily attack the mucosa of the small intestine. The anthrax bacillus is a saprophyte except in the cutaneous tissue. The staphylococcus and certain types of streptococci select the skin for their attack. Immunize these tissues and the infection cannot occur.

According to Besredka's own confession, the idea of local immunity had its genesis in a study of immunity to anthrax in guinea pigs. Ordinarily, these animals are most susceptible to this infection, yet when they were inoculated with many times the lethal quantity of anthrax bacilli in such a manner as to avoid injury to the skin or contact of bacilli with the skin, they resisted the invasion, in fact gave no symptoms whatsoever. They acquired no immunity as the result of inoculations of this type. If, however, the skin was vaccinated either by intracutaneous inoculation or by direct application of the vaccine,

the animal became immune to anthrax infection. Such an immunity was not accompanied by the presence of demonstrable antibodies, nor was it possible to immunize passively a second animal by means of a serum from a completely immunized guinea pig. There is at present little tendency to dispute these observations. In so far as anthrax is concerned, the fundamental observations have been repeatedly confirmed not alone with guinea pigs but with rabbits. The principle of "cuti-immunization" has been applied to the protection of large animals on a broad scale and in so far as may be judged by the reports available has been eminently successful.

Although not the only tissue susceptible to the attack of staphylococci and streptococci, the skin is particularly subject to infection. It may be said that these cocci have a predilection for such tissue. Consequently it was not long after the establishment of anthrax immunization by means of intracutaneous inoculation that Besredka and others attempted similar work with the pyogenic cocci. They succeeded. In animal experiments they were able to confer a very high degree of immunity by intracutaneous inoculation of killed cultures, or by application of dressings soaked in such material or soaked in filtrates of old cultures of these organisms. The success attending these experiments was not so complete as that attending anthrax immunization; yet it was considerable and sufficient to warrant the application of the method to treatment of such infections in man.

In dysentery and typhoid fever the mucosa of the small intestine is the susceptible tissue. If the organisms causing these diseases are introduced into animals by any route they will localize in this tissue. Further, by rendering such tissue more permeable through damage such as may be produced by bile, animals ordinarily immune may be made to undergo a typical typhoid or dysentery infection. Conversely, a very considerable immunity may be conferred by introduction of killed cultures into the small intestine, which preferably has been previously prepared by ingestion of a small amount of bile. Again these findings have been carried over to human application with results sufficiently striking to warrant further investigation.

Although not described in Besredka's monograph, his method of immunization has been applied to many other infections, and has become in addition a method of treatment. Tuberculosis and gonorrhea in particular have been the subject of extensive investigation. Like all problems involving treatment of man, there is required too much of detail and of control to make evaluation possible at the present time.

So much of Besredka's monograph as depends upon observed phenomena is not difficult to accept, especially in view of the ample sup-

port it has received. That part of his work bearing upon an explanation of these phenomena is less easily digested. As in the case of bacteriophage, the consideration of underlying causes bids fair to overshadow the very practical accomplishments. This is unquestionably necessary, for it is inconceivable that a therapeutic measure could come into general use without a rational basis for its acceptance. The greatest difficulty seems to concern the denial of antibodies in the immunity produced. This is, for many, a pill hard to swallow.

No brief summary can do justice to Besredka's ideas, but some suggestion of his method of reasoning may challenge a more intensive study of the theory. According to this author, immunity is largely dependent upon phagocytosis. Providing that leucocytes can be brought into contact with bacteria, phagocytosis occurs. The idea of *positive* chemotaxis Besredka rejects. Except in the presence of negative chemotaxis it is the normal function of phagocytes to approach, surround, ingest and if possible to digest foreign bodies. When a tissue is susceptible to invasion by a given organism it possesses receptors which Besredka thinks may reside in some of the reticuloendothelial cells in that tissue. These receptors in conjunction with the invading organisms produce a state of *negative* chemotaxis which prevents phagocytosis and allows the establishment of infection. Contact of the susceptible tissue with the organism, rendered noninvasive, exhausts these receptors and hence provides for immunity by making possible immediate phagocytosis upon invasion by viable organisms. The exhaustion of the receptors depends not upon the bacterial antigen but upon a substance associated with bacteria. It is present in small quantities in heat killed vaccines but is much more abundant in filtrates of old cultures. This substance Besredka calls antivirus. Hence it has come about that the terms antivirus and local immunization are practically inseparable.

No one reading Besredka's monograph or the abundant literature upon the subject can help believe that as a method, local immunization has much to recommend it. One is likely to feel equally impressed with the weakness of the theory which supports it. This fact should lead to intensive investigation either to strengthen the theory or to provide another having fewer weaknesses. French, German, and Italian investigators have attacked this problem. The literature in the English language is practically nil. It is difficult to state what is needed to bring this problem to the attention of investigators in this country. The question is so dependent upon a combined clinical and laboratory investigation that it requires a united attack by physicians and laboratory investigators such as can best be provided by a sub-

sidized group. In view of the magnitude of the problem it is not too much to hope that America will not long remain in almost complete ignorance of this subject.

Enemies of Knowledge

ONE last word. It is possible to hold strong opinions and still to be tolerant. We must have theories, and we may believe them very implicitly, if we are to progress. A sheer accumulation of facts will gradually overwhelm the human brain, if no means of ordering them be available. We must, however, continually reflect upon the possibility that after all we may be wrong. So long as we do nothing unfair to other people and their theories, so long as we do not interfere with their liberties in the pursuit of their lawful business, our own strong beliefs, our own stupidity and ignorance, may be forgiven.

Inside the front page of a recent book on physical astronomy a friend of mine has pasted a cartoon of a young lady talking to an old fisherman: "What did you think," she says, "of last night's wireless lecture on the atom?" "Never heard such a pack of lies in my life." That, however, is not the same thing as intolerance; no old fisherman would wish to burn, to imprison, or even to pray for the deaths of Professor Eddington and Sir James Jeans. I do not much care if the Countess of X, or her friends in the Government, take the same cheerful view that the results of medical research are a "pack of lies." That is her business, and, after all, I probably have the same contempt for many of her sacred beliefs. I am content to leave the decision between us in such matters to the public intelligence. What I do protest against, and would fight against with all my strength, are calumnies and persecution, and attempts at legal interference with our liberties, wantonly intended to hinder the advance of knowledge; or national and political hatreds which prevent coöperation in the greatest of human quests; or theories, however well grounded, which their owners cannot conceive as being otherwise than true. In such matters, after all, modesty, friendliness, humanity, judgment, balanced by a reasonable sense of humour, are, as in other things, the basis of human welfare.—A. V. Hill. From *The Lancet*, June 29, 1929, p. 1388.

LABORATORY STUDIES OF YELLOW FEVER

MORE than two years have elapsed since the discovery that the *Macacus rhesus* monkey may be inoculated successfully with yellow fever. The finding of a suitable laboratory animal opened a new era of research in yellow fever, and the work published so far has not only confirmed the essential findings of the Army Yellow Fever Commission under Walter Reed, but has also made a considerable addition to new knowledge.

The discovery that yellow fever is transmissible from man to monkey was made by Stokes, Bauer, and Hudson[1] of the West African Yellow Fever Commission of the Rockefeller Foundation. It was confirmed in Senegal by Mathis, Sellards, and Laigret,[2] and later in Brazil by Aragão.[3] The virus soon became available for study in Europe and America, as Sellards[4] was able to transport it in frozen monkey liver from Senegal to England, and from there to the United States. Later it was sent successfully from Nigeria direct to the United States under various methods of preservation. Up to the present, yellow fever virus from West Africa has been studied, through the use of monkeys, in Lagos, Accra, Dakar, London, Paris, Berlin, Amsterdam, Rio de Janeiro, Bahia, Boston, and New York, and the virus from South America has been similarly investigated in Rio de Janeiro, Bahia, and New York. The methods of preservation of the virus for storage or for shipment between laboratories have been improved step by step until it is now possible, according to Sawyer, Lloyd, and Kitchen,[5] to desiccate blood-virus in the frozen state and keep it in sealed tubes for at least 150 days.

One of the great needs in yellow fever control operations and in the preliminary epidemiological studies is a specific diagnostic test by

which the mild and recovered cases can be identified and the endemic areas ascertained. As yet no simple and inexpensive test has been found, but it is possible, by the use of monkeys, to determine whether a person has had yellow fever. The serum from a recovered patient, when injected in suitable amounts, will protect a susceptible monkey against a subsequent inoculation of the virus.

The monkey commonly used is the *Macacus rhesus* from Asia, but several other species of the same genus are susceptible, and Davis and Shannon[6] have found that a South American monkey, *Cebus macrocephalus,* is possibly slightly susceptible. By means of such protection tests Theiler and Sellards[7] and also Hudson, Bauer, and Philip[8] have shown that the serum of persons who had recovered from yellow fever in the Western Hemisphere protected against African strains of the virus. One of the protecting serums had been taken from a person who had had yellow fever in Peru 7 years before. These experiments add to the evidence that yellow fever as found in Africa is the same disease as that found in the Americas.

Bacteriological studies of yellow fever in monkeys have, as a rule, failed to reveal any organism which could be considered the cause of yellow fever. The single outstanding exception is the announcement by Kuczynski[9] of a bacterial organism which he believes is related to the disease. The filterability of the virus in blood serum has been again demonstrated by Stokes, Bauer and Hudson[1] and the causative agent is generally considered to be one of the filterable viruses. This classification has recently been supported by the discovery by Torres[10] of intranuclear inclusions in the liver cells of monkeys which had been inoculated with Brazilian strains of yellow fever virus. These inclusions are made up of clusters of acidophilic particles and are suggestive of the intranuclear inclusions of herpes. Similar inclusions were later found by Torres[11] in monkeys inoculated with African virus. The intranuclear inclusions have been studied by Cowdry and Kitchen,[12] who found them in monkeys inoculated with an African strain of yellow fever and also in human yellow fever tissues from Africa and the Western Hemisphere. Pathological studies of the tissues of monkeys dead of yellow fever have been made by Hudson,[13] who is of the opinion that the lesions are strikingly parallel to those produced by yellow fever in man.

The virus of yellow fever is easily transmitted from monkey to monkey by the mosquito *Aëdes* (*Stegomyia*) *aegypti,* the well known transmitter of yellow fever and dengue. By the use of laboratory animals, the virus in the mosquito can be studied more closely than formerly when the work involved the use of human volunteers. The

incubation period in the insect has been found, by Bauer and Hudson,[14] to vary from 9 to 12 days, and they demonstrated also that the mosquitoes contain virus in infectious form throughout the incubation period, although their bites are then harmless.

Perhaps the most significant result of the studies of the mosquito is the finding that the common stegomyia is not the only mosquito capable of transmitting yellow fever. A number of species have been studied in Africa by Bauer,[15] and under laboratory conditions yellow fever was transmitted by the bites of the following species: *Aëdes luteocephalus, Aëdes apicoannulatus,* and *Eretmopodites chrysogaster.* It is still a matter of speculation whether any of these three species helps spread yellow fever under natural conditions.

The work of the Army Commission in Cuba and the general experience with post-mortem examinations had shown that objects contaminated by yellow fever patients and the bodies of persons dead of yellow fever are not dangerous. It appears, however, that those who work with the highly infectious blood or liver emulsion of infected animals are in great danger. Eight accidental infections with yellow fever have been reported in bacteriologists working in laboratories with the experimental disease in monkeys, and 4 have lost their lives: Adrian Stokes, Hideyo Noguchi, William A. Young, and Paul A. Lewis. The method of entry of the virus was a mystery to those infected. It was shown by Bauer and Hudson,[16] however, that the virus may infect monkeys through the intact skin, when virus-bearing monkey blood is applied. This may help explain the tragic laboratory accidents. Injections of convalescent yellow fever serum have been used in Africa as a preventive after minor accidents in the laboratory.

A safe method of active immunization against yellow fever is urgently needed to protect individuals in epidemic and endemic areas and also the persons engaged in yellow fever investigation and control. A vaccine has been prepared by Hindle[17] from cytolyzed monkey liver and spleen tissue to which 2 parts of formaldehyde per 1,000 have been added. This vaccine has protected monkeys against inoculation with yellow fever virus, and the British Colonial Office is considering giving it a trial in West Africa. In Brazil, Aragao[18] made a vaccine from monkey tissues to which phenol and formaldehyde were added. This vaccine has already been administered to many thousands of persons; but, because of the poor results obtained, its use has recently been abandoned. It will take time, therefore, to determine the degree of protection to be expected through the use of these vaccines in human beings.

The high protective power of convalescent serums of man or

monkey has led to experiments to produce even more potent serums by hyperimmunization of animals. Pettit, Stefanopoulo, and Frasey[19] have prepared potent immune serums from various animals including monkeys and horses. Unfortunately, immune serums appear to be of no avail in the treatment of yellow fever in man or monkey after symptoms are established.

The journals are constantly bringing forth the announcement of new results of yellow fever research. Each increase in knowledge should hasten the day when yellow fever control measures can be simplified, and made easier of application among primitive peoples.

LEADERSHIP IN AMERICAN PUBLIC HEALTH

LEADERSHIP in American public health now rests with the southern states. Not only have they made the greatest progress in recent years in the organization of their public health services but they seem to show most promise in their readiness and ability to extend and perfect their organizations to the point of adequacy. The richer and more complacent northern and eastern areas of the country have much to learn from their sister states below Mason and Dixon's line. It is hoped that they will not lose much time in profiting from the admirable lesson.

The history of this shifting of leadership to the southern states is full of interest. Massachusetts was the first state to develop a public health department as we now conceive it. Under the inspiration of Shattuck, Walcott, Bowditch, Abbott, and later Professor Sedgwick, Massachusetts showed the way to the rest of the country. New Jersey, Michigan and New York early did sanitary work of a high order, and New York State especially reached an enviable position later through the constructive genius of Hermann M. Biggs. But while these and other northern states were perfecting their centralized or-

ganizations, a new development began in the South. The surface of public health effort had barely been scratched in this large area of the country. Health problems of the first order called for attention. Under able guidance and the coöperation of state and federal health officials, a host of local health activities began to spring up. The keynote of this work was the perfection of local units of rural health service. Their plan called for decentralization rather than the perfection of the state health office.

From the very beginning, the International Health Board of the Rockefeller Foundation aided the organization of well conceived local full-time services in a number of states by contributing funds and the services of its staff. Primarily concerned with the control of hookworm disease, these local health units later were strengthened and took on the other functions of a well organized health agency. North Carolina did pioneer work in this field; later Alabama and Mississippi and, more recently, Tennessee, have perfected organizations approaching a state-wide basis of full-time county health units. Virginia, Kentucky, Louisiana, South Carolina, Georgia, Arkansas, Maryland and Missouri have taken up the program.

To facilitate the manning of local units with competent personnel, thriving stations for the training and appraisal of health officers, sanitary inspectors, and nurses are to be found in a number of states. Today, we find in the South a vigorous and growing movement for the completion of health organization on this tried and proven basis of full-time, competent county health service. There is no part of the country where more vigorous rural health activity can be seen in operation, where money is being spent more wisely, and where better results are obtained than in the South.

It is literally true that when health observers from abroad come for the study of our best rural work, it is necessary to take them to such southern states as Mississippi and Tennessee rather than to the northern states where health work has been in operation much longer and where brilliant achievements were recorded in the past. Possibly it would be more charitable to say that health work in most northern states, being older, has reached a more or less static condition in relation to basic needs. But there is little to inspire in this situation.

It would be unfair, however, to say that the new development is entirely limited to the South. The movement for full-time county health service early made its impress in Ohio where the organization is as extensive and as effective as anywhere, but Ohio is rather an exception among the northern states. Michigan is beginning to come along.

Iowa and Wisconsin have just passed admirable permissive laws for county health service. There are indications of murmurings which presage a similar movement in other states of the North and East in the immediate future. New York has recently shown that it is possible under its law to organize on the full-time county unit plan. But there are only a few units, where 50 or 60 are possible. It would be a great gain to the whole movement if New York State could organize itself widely on the full-time county plan functioning with the traditional efficiency of this state's health department. When this happens, a new era in American health work will be ushered in.

THE IODINE CONTENT OF FOODSTUFFS

AN interesting study which has great possibilities is being carried on in South Carolina by the departments of physiology and pathology of the Medical College of the state (the field force of the State Board of Health), and several physicians.

In 1928 the legislature created a commission and provided funds for studying the mineral elements of foodstuffs growing in the state. The prime mover was Dr. William Weston, a pediatrician, whose interest was aroused through the problems of nutrition. The analyses are being done by Prof. Remington of the Medical College.

While similar data for the entire country are not available for comparison, it can be said that the vegetables grown in South Carolina contain from twenty to thirty times as much iodine as those produced in California and Oregon. An unexpected finding is that the vegetables from the Piedmont region are somewhat richer in iodine than are those grown in the coastal belt. The green leafy vegetables show the largest amounts of iodine and are also the richest in vitamins and iron. The root crops are also rich in iodine, but grains, regardless of where they are grown, are poor in this element.

It has been found that the river water which showed the highest content of iodine is some 150 miles from the coast. This particular stream did not contain other salts, which would indicate that they were derived from wind-borne spray from the sea. These findings are contrary to the former theory that iodine and other salts were obtained from the ocean through wind-blown spray. Another theory seems to have been disproved by the analyses as far as they have gone. Nitrates from Chile have been used to a considerable extent as fertilizer, and some have supposed that iodine was derived from this source. However, Chilean nitrate contains only a few hundredths of one per cent of iodine and the section of the state which shows the highest

goiter incidence and the lowest amount of iodine in the foodstuffs is that in which Chilean nitrate has been most largely used over a number of years. On the other hand, such vegetables as peas and beans, which contain large amounts of iodine, are not fertilized with nitrate.

The examination for service during the World War showed that those drafted in South Carolina had an incidence of simple goiter of 0.25 to 1.00 per 1,000. The findings, so far, indicate that in South Carolina, at any rate, the vegetables are a more important source of iodine than the water supplies.

Certain preliminary analyses indicate that those foods which are rich in iodine are also relatively rich in iron and manganese. It has already been pointed out that the vegetables which are richest in iodine are also rich in vitamins and iron.

The studies are to be continued, combined with feeding experiments. The results are interesting and important, and we hope that they will serve to broaden the investigations on endemic goiter from a study of waters, to which they have so far been largely confined, to the elements concerned in nutrition.

Epidemiology Section

THE Executive Board at its meeting, December 8, 1928, appointed officers for the Section on Epidemiology, established by the Governing Council October 18, 1928, in Chicago.

The organization of this section is intended to meet a definite need for a group of earnest public health workers who are primarily interested in the study and the practice of epidemiology, by whatever title the bureau or department to which they belong may be designated.

Fellows and members of the Association who are at present engaged in lines of work where their major interests are in this field, should designate to the Executive Secretary their desire for a connection with the Section on Epidemiology and apply for transfer. Persons interested in this field who are not now members of the Association should find in this section an outlet for their contributions to the subject, and stimulating contact with those in similar fields, in state or city departments.

Applications for transfer from other sections, and applications for membership to this section should be in the hands of the Executive Secretary of the Association well in advance of the Minneapolis meeting.

A stimulating program has been prepared for the meetings of this section, as well as for the joint meetings with the Health Officers' Section and the Laboratory Section.

DON M. GRISWOLD, *Chairman*
E. S. GODFREY, JR., *Vice-Chairman*
HAVEN EMERSON, *Secretary*

ASSOCIATION NEWS

Minneapolis Will Entertain Her Guests

MINNEAPOLIS is a convention city, not only for its new Municipal Auditorium, excellent hotel accommodations, accessibility by rail, airplane, or motor car, but also because of its great educational institutions, the large measure of health consciousness among its people, its natural beauty, remarkable scenic development, and its hospitality toward its visiting guests.

The American Public Health Association, the American Child Health Association, the International Society of Medical Health Officers, the American Social Hygiene Association, the American Association of School Physicians, the Conference of State Sanitary Engineers, and the State Laboratory Directors are among the guests Minneapolis delights to honor.

It is happy to be assisted in their entertainment by the State Sanitary Conference, the Minnesota State Public Health Association, and the State Nursing Organizations. With this unique occasion it will associate the third annual session of the Northwest Conference for Child Health and Parent Education, and, finally, under the joint auspices of the American Public Health Association, and the Northwest Conference, the first Educational Health Exhibit for the benefit of the people at large will be presented. A prospectus of the Exhibit will be issued soon.

ENTERTAINMENTS AND TRIPS

1. The health organizations are invited to join the University of Minnesota in the Dedication of the Public Health Pavilion upon the Medical Campus on Tuesday, October 1, 1929, at 9:00 A.M. The program follows:

   a. Welcoming Address, by Dr. Lotus Delta Coffman, Chancellor of the University of Minnesota
   b. Dedicatory Address, " The Doctor, the Health Officer, and the Community," by Dr. C.-E. A. Winslow, Director of the Anna M. R. Lauder Department of Public Health, Yale University
   c. An Address upon " The Evolution of Student Health Services," by Dr. Harold S. Diehl, Director of the Minnesota Service and Chief of the Department of Preventive Medicine and Public Health
   d. An Address upon " The University in Relation to Public Health Work," speaker to be announced later

The program will be followed by a complimentary luncheon in the Ball Room of the Minnesota Union.

2. A drive will be arranged through the immediately surrounding lake district to the Glen Lake Sanatorium and the Children's Preventorium for Tuberculosis, an institution of 660 beds. Buffet Luncheon will be served.

3. A drive to the University of Minnesota Main Campus and the Agricultural Campus—the fourth university in point of registration in the United States.

4. A trip to the hospitals and educational institutions of the Twin Cities for the care and rehabilitation of the handicapped, including the Minnesota Hospital for Crippled Children, the Shriners' Hospital, the Arthur J. Gillette State

Hospital for Crippled Children and the Michael Dowling School.

5. A visit to the Citizens' Aid Building, the unique home of the social and health agencies of the city.

6. A visit to the University Medical Schools, and the University Hospitals, including the Cancer Institute, the Frank C. Todd Memorial Clinic and the Eustis Hospital.

7. A trip for the sanitary engineers and State Sanitary Officers to the water filtration plants and to the proposed sites for river purification plants.

8. A trip to the milk producing, pasteurizing and distributing plants.

9. A trip to the Minneapolis flour mills.

10. Two alternative drives for visiting ladies:

a. To Lake Minnetonka and intervening lakes and boulevards, ending up with an afternoon tea at the Minneapolis Art Institute

b. Around the lakes and boulevards surrounding the city, to the Falls of Minnehaha, returning by the River Roads and the Victory Drive, ending up with an afternoon tea proffered by the Minnesota State Organization for Public Health Nursing at the Minneapolis Woman's Club

11. A trip to the hospitals and public institutions of Saint Paul, to be offered by the profession and the citizens of the city's twin, is suggested.

12. At the Opening General Session of the Visiting Health Organizations, on Monday evening, September 30, a dance will be given by the Local Committee at the Hotel Nicollet.

13. The Minnesota State Public Health Association will arrange a dinner at the Hotel Nicollet, on Tuesday evening, October 1, to be followed by an interesting program of speakers and musical entertainment (Tickets, $2.00).

14. The Annual Banquet of the American Public Health Association and its allied organizations will be held on Thursday evening, October 3, in the Grand Ball Room of the Hotel Nicollet (Tickets, $2.50). At the after-dinner program, Dr. George Edgar Vincent, President of the Rockefeller Foundation, will make the opening Address. Other speakers will be announced. The banquet and program will be followed by a dance given by the Local Committee.

15. A special trip, by fast railway service, to the Mayo Clinic and the Mayo Foundation, Rochester, Minn., will be provided late on Friday evening, October 4; leaving Minneapolis at 9:40 P.M. A research health program will be presented for Saturday morning, October 5. Visits to hospital clinics will be arranged.

A complimentary luncheon will be arranged for Saturday noon, followed by an informal program, and an early afternoon visit to the Saint Mary's and the Kahler Corporation Hospitals.

Trains will leave Rochester for Minneapolis at 4:00 P.M., and for Chicago at 9:30 P.M. on Saturday.

The guests of Minneapolis for the public health meetings will greatly facilitate the work of the Local Committee if they will make *advance reservations* (1) for the University Dedication Exercises and Luncheon on Tuesday morning; (2) for the Minnesota State Public Health Association dinner on Tuesday evening; (3) for the Annual Banquet on Thursday, October 3; and (4) for the Mayo Visit and luncheon. Its officers will be gratified if reservations are also made, so far as possible, in advance, for other entertainments and trips.

Address: Richard Olding Beard, M.D., Executive Secretary for the Local Committee, 324 Citizens' Aid Building, Minneapolis, Minn.

Sedgwick Memorial Medal

THE Sedgwick Memorial Medal Committee has accepted a design for the Sedgwick Memorial Medal prepared by Mary Hooker Donelson. This design was selected as the prize winning design in a contest arranged by Professor E. O. Jordan in coöperation with M. J. Rosenau, M.D., and Robert Spurr Weston.

This medal is given in memory of the late Professor William T. Sedgwick, who was President of the American Public Health Association in 1915. It was made possible by a contribution of funds by Professor Sedgwick's friends and former students. The medal is to be awarded for distinguished service in public health work, the winner of the award to be selected by the Sedgwick Memorial Medal Committee of the American Public Health Association, from candidates who have been nominated for this purpose.

It is expected that the first award of the medal will be made at the 58th Annual Meeting of the Association at Minneapolis, Minn., during the week of September 30. Nominations should be addressed to the Secretary, Homer N. Calver, 370 Seventh Avenue, New York, N. Y.

EVA F. MACDOUGALL NEW EDITOR

Since the February, 1927, issue of the JOURNAL, Miriam Ames, R.N., Assistant Director, Visiting Nurse Service, John Hancock Life Insurance Company, has edited the Public Health Nursing Section. Recently, however, because of the pressure of her work with that company, Miss Ames has found it impossible to continue her work for the Journal.

Eva F. MacDougall, R.N., Director of the Division of Public Health Nursing, Indiana State Board of Health, has been appointed editor of the Public Health Nursing Section in Miss Ames' place, and begins her contributions with the present issue.

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, provided such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Minneapolis will be elected for the three-year term, 1929–1932.

T. B. Beatty, M.D.,
State Health Commissioner,
Salt Lake City, Utah

E. L. Bishop, M.D.,
State Health Commissioner,
Nashville, Tenn.

A. J. Douglas, M.D.,
City Health Department,
Winnipeg, Man.

William A. Evans, M.D.
Chicago Tribune,
Chicago, Ill.

I. S. Falk, Ph.D.,
Department of Hygiene and Bacteriology,
University of Chicago, Chicago, Ill.

John A. Ferrell, M.D.,
International Health Division,
New York, N. Y.

Prof. J. G. Fitzgerald,
Connaught Laboratories,
University of Toronto, Toronto, Ont.

A. H. Flickwir, M.D.,
Health Officer,
Fort Worth, Tex.

W. H. Frost, M.D.,
Johns Hopkins University,
Baltimore, Md.

J. C. Geiger, M.D.,
University of California Medical School,
Hooper Foundation, San Francisco, Calif.

Don M. Griswold, M.D.,
Deputy Health Commissioner,
State Dept. of Health, Springfield, Ill.

Prof. Ira V. Hiscock,
Department of Public Health,
Yale University, New Haven, Conn.

Thomas G. Hull, Ph.D.,
Diagnostic Laboratory,
Department of Health,
Springfield, Ill.

John F. Norton, Ph.D.,
Department of Health Laboratory,
Herman Kiefer Hospital,
Detroit, Mich.

H. L. Rockwood, M.D.,
Health Commissioner,
Cleveland, O.

Clyde C. Slemons, M.D.,
Health Officer,
Grand Rapids, Mich.

H. A. Streeter, M.D.,
City Isolation Hospital,
Manchester, N. H.

Benjamin White, Ph.D.,
Antitoxin & Vaccine Laboratory,
Jamaica Plain, Mass.

Huntington Williams, M.D.,
State Department of Health,
Albany, N. Y.

Shirley W. Wynne, M.D.,
Health Commissioner,
New York, N. Y.

NOMINATING COMMITTEE

James Roberts, M.D., *Chairman*
C. C. Young, D.P.H. Abel Wolman

PHOTOGRAPHS OF PAST PRESIDENTS

There is being assembled in the Executive Office of the Association a collection of photographs of past presidents of the Association. This collection is fairly complete for recent years, but the assistance of members and Fellows of the Association is requested in filling the many gaps in this gallery. The only photographs which we have been able to secure of presidents previous to 1900 are those of the first 10 presidents, and the following:

Henry P. Walcott—1886
George M. Sternberg, M.D.—1887
Samuel H. Durgin, M.D.—1893

Subsequent to 1900 the collection is complete with the exception of the following:

Benjamin Lee, M.D.—1901
Walter Wyman, M.D.—1903
Domingo Orvananos, M.D.—1907
G. T. Swarts, M.D.—1909
R. M. Simpson, M.D.—1911
Rudolph Hering, Sc.D.—1913

Any member or Fellow of the Association who may have or have access to pictures of any of the past presidents which are not included is urged to communicate with the Executive Secretary.

NEW MEMBERS

I. Alexa, M.D., C.P.H., Iasi, Roumania, Instructor in Bacteriology (Assoc.)
James M. Brannon, Ph.D., Urbana, Ill., Dairy Bacteriologist
A. D. Brewer, M.D., Bozeman, Mont., City-County Health Officer
Ethel G. Bright, R.N., Swainsboro, Ga., Emanuel County Nurse
Eula B. Butzerin, R.N., Minneapolis, Minn., Director of Course in Public Health Nursing, University of Minnesota
Belle Carver, R.N., Brooklyn, N. Y., Industrial Nurse, United States Rubber Co.
C. A. Christensen, M.D., Dearborn, Mich., Commissioner of Health
T. C. Colley, M.D., Keller, Tex., Health Officer of Tarrant County
Joseph R. D'Aunoy, M.D., New Orleans, La., Director of Laboratories, Charity Hospital
Harold S. Diehl, M.D., Minneapolis, Minn., Director, Student's Health Service
Zephirin Dupuis, M.D., L'Assomption, P. Q., Medical Officer
M. A. Fort, M.D., Dr.P.H., Bainbridge, Ga., Health Commissioner of Decatur County
J. P. Greenhill, M.D., Chicago, Ill., Obstetrician and Gynecologist
Anna J. Haines, R.N., Boston, Mass., Executive Secretary, Boston Health League
Mrs. Lynn G. Hooper, R.N., Jackson, Miss., Supervising Nurse, Hinds County Health Department
Roy C. Kester, Greenville, O., Chief, Division of Sanitary Inspections, Darke County Health Department
James F. King, B.S., Atlanta, Ga., State Chemist
Jordan Lally, M.D., New York, N. Y., Industrial Physician, United States Rubber Co.
Eugene M. McCarty, M.D., Rumford, Me., Medical Director of the Oxford Paper Co.
Carl C. Mann, Arlington, N. J., Industrial Physician, DuPont Viscoloid Co.
Agnes E. Maynard, R.N., Hamilton, N. Y., Supervising Nurse, State Department of Health
Fredrika Moore, M.D., Boston, Mass., School Health Worker, State Department of Health
Mary R. Noble, M.D., Harrisburg, Pa., Chief, Preschool Division, State Department of Health
Henry G. Oldfield, M.S., Minneapolis, Minn., Assoc. Sanitarian, Milk Sanitation, State Department of Health
George M. Piersol, M.D., Philadelphia, Pa., Medical Director, Bell Telephone Co.
William Pralle, Houston, Tex., Assistant Engineer, Department of Health
Ella H. Rigney, New York, N. Y., Publicity Director, American Society for Control of Cancer
John O. Salyers, M.D., Hazard, Ky., Director of Health, Perry County
Sherwood H. Smith, A.B., Jacksonville, Fla., Executive Secretary, Florida Public Health Association
Antonio Vidal, M.D., D.P.H., Honduras, C. A., General Inspector of Public Health (Assoc.)
Samuel B. Woodward, Worcester, Mass., President of the Worcester County Institute for Savings (Assoc.)

APPLICANTS FOR FELLOWSHIP

PUBLIC HEALTH EDUCATION SECTION: B. S. Stephenson, M.D., Sidney, O.
FOOD, DRUGS AND NUTRITION SECTION: John S. Abbott, Washington, D. C.
CHILD HYGIENE SECTION: Ada McMahan, M.D., Lafayette, Ind.
HEALTH OFFICERS SECTION: Charles H. Benning, M.D., Royal Oak, Mich.; David M. Cowgill, M.D., Twin Falls, Ida.; Gordon T. Crozier, M.D., Valdosta, Ga.; Walter W. Lee, M.D., Indianapolis, Ind.
PUBLIC HEALTH NURSING SECTION: Elsbeth H. Vaughan, St. Louis, Mo.
VITAL STATISTICS SECTION: Mary A. Clark, New York, N. Y.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Diphtheria Prevention in New York City—It was the ancient custom to shake a rattle to keep the evil spirits of disease away. Today we keep the "evil spirits" away by "shaking the rattle" of the mighty microphone, the far-flung film, the trenchant pen, the powerful printing press and mostly by the patient work of great scientists.

The Diphtheria Prevention Commission of the New York City Department of Health records the results of 5 months of modern "rattling" to conquer the evil spirits of diphtheria: 300,000 toxin-antitoxin injections administered; 100,000 children immunized. More than 50 per cent have been of preschool age. Nearly 50 per cent have been treated by private physicians; 120,000 placards displayed for 7 weeks in the subways, elevated, street cars, buses, ferries, etc.; 500,000 homes received pastoral letters issued by Cardinal Hayes, and a message from Bishop Thomas E. Molloy; 2,000,000 pieces of literature have been distributed—some translated into Yiddish, Finnish, Italian, Polish, Greek, Spanish, Japanese and Lithuanian; 5,200,000 people heard our diphtheria movietone in the theatres; 300,000 copies of six Health Tabloids issued; 25,000 handbooks of information issued; 200,000 families canvassed by family physicians; 4,000,000 pieces of literature are being distributed with the statements of gas and electric companies; 11,345 waiting room cards distributed to physicians for permanent posting in their reception rooms; 86 diphtheria stations in operation for those who cannot afford the services of private doctors; 10,000 letters sent each month to mothers whose babies reach their 9th month; 36 daily newspapers and 83 weeklies and semi-weeklies in foreign languages carry our news messages; 2 of the largest moving electric signs in the world are being utilized for our diphtheria message through the generosity of companies operating these signs; 6 "Healthmobiles"—newly equipped Diphtheria Protection Stations on wheels—are carrying diphtheria protection to those children in the congested districts of New York whose parents cannot afford either a physician or a summer holiday. Each truck is manned by a doctor and 2 nurses.

The plan for the fixing of minimum fees for diphtheria immunization to enable the mass of people of moderate means to patronize the private practitioner is now well under way.

Coöperating with the Board of Education Census every home in the Bronx (population 951,900—equal to the whole population of Boston) is now being canvassed, and all children under 15 years—estimated at 150,000—are being followed through to demonstrate the possibility of a diphtheria-free borough.

Seven hundred and fifty 24-sheet posters were displayed at strategic outdoor places throughout the city for 1 month. Fifty of New York's leading citizens constitute the Diphtheria Prevention Commission.

Nine distinguished pediatricians, headed by Dr. Bela Schick and representatives of the 5 county medical societies, constitute a Technical Consultation Board.

Twenty-one leading social welfare and

health organizations comprise an Executive Board of Coöperating Agencies.

Thirty-two editors of newspapers have formed an Editorial Consultation Board.

One hundred and seventy-nine prominent foreign born men and women nominated by 35 Consul Generals serve on a Foreign Groups Committee.

The City of New York under the leadership of Mayor James J. Walker and the immediate supervision of the Health Commissioner, Dr. Shirley W. Wynne, has placed the resources of the Department of Health at the disposal of the commission to the end that diphtheria be wiped out in New York.

The diphtheria campaign is being conducted with funds donated by public spirited groups interested in the public health.—Edward Fisher Brown, Director, Diphtheria Prevention Commission.

General Files for Small Health Departments—The large number and variety of subjects about which health departments have correspondence, together with the necessity for maintaining files of information, make it absolutely essential that there be a general filing system which is simple and effective. The test of effectiveness is twofold: first, the ability to file rapidly and easily, and second, the ability to find material with equal ease and rapidity.

The Racine Health Department is using a general filing system based upon the *Appraisal Form for City Health Work*. The numerical plan of filing is followed, with alphabetical subject index.

The general subject headings under which the filing is carried out, as based upon the *Appraisal Form*, is shown in Table I.

It is impossible in the space here available to go into detail and set forth all of the 1,000 titles. A few divisions are therefore shown as a general guide. Each class of 100 numbers is again subdivided into 10 groups of 10 numbers each (see Table II).

TABLE I

GENERAL CLASSIFICATION

Class	*Numbers*	*Subjects*
0	1–100	Administration
I	101–200	Vital Statistics & Records
II	201–300	Public Health Education
III	301–400	Preventable Diseases
IV	401–500	Maternal and Child Welfare
V	501–600	Food and Sanitation
VI	601–700	Medical, Nursing, Hospital and Clinics
VII	701–800	Reserved for future use
VIII	801–900	Coöperating Agencies
IX	901–1000	Miscellaneous Topics

TABLE II

DIVISION OF CLASSES INTO GROUPS (CLASS 0)

1–100	*Administration*
1–10	Organization
11–20	Personnel
21–30	Finance
31–40	Policy
41–50	Reports, outgoing
51–60	Reports, incoming
61–70	Permits and Licenses
71–80	Inventory
81–90	Supplies
91–100	Miscellaneous

The other groups are subdivided in similar manner. For example, group II, which is Public Health Education (201–300), includes sub-titles given in Table III, to each of which 10 numbers are assigned.

TABLE III

DIVIDING CLASSES INTO GROUPS

201–300	*Public Health Education*
201–210	Health Department Publications
211–220	Other Publications
221–230	Lectures
231–240	Exhibits
241–250	Health Department Library
251–260	Open
261–270	Open
271–280	Open
281–290	Open
291–300	Open

Each of the groups is again divided into 10 unit numbers. For example, in group V, Food and Sanitation (501–600), we take group 511–520 for illustrations (see Table IV).

TABLE IV

DIVIDING GROUPS INTO UNITS

511–520	*Milk and Cream*
511	Farms
512	Dairies
513	Stores (cf. 531–540)
514	Examinations
515	Licenses
516	Ordinances (cf. 2)
517	Grading
518	Adulteration
519	Studies
520	Other cities

In each group there remain a number of unused numbers and titles to allow for the addition of new titles which may be needed. This is in addition to the group of 100 numbers above mentioned which is also being held in reserve.

The necessary equipment and material for the installation of this filing system together with the cost are shown in Table V.

TABLE V

EQUIPMENT

1	4-drawer steel letter size vertical file	$57.00
10	press board guides, metal tab, center position	1.20
100	press board guides, left hand position, tab	6.00
1000	manila letter folders, 1/3 cut, right hand position	19.00
1	visible index binder, capacity 1500 titles	16.00
1500	visible index file cards	8.25
	Total	$107.45

Any office supply dealer will be able to furnish this equipment, which is the standard equipment used for "direct name" systems of filing. The metal tabbed guides are to designate the 10 main divisions, of 100 numbers each. The left hand tabbed guides are for the sub-groups of 10 numbers each. Each unit number has a folder.

Preparation of the system consists first in drawing up the general plan and assigning classes, groups and unit numbers to appropriate titles. For each title a folder is then prepared. Folders are also prepared with numbers only for the untitled numbers to be held in reserve.

The index consists of a visible card for each main group, sub-group and unit number. These are numbered and titled, using "capital and lower case" for the unit number titles and "full capitals" for the sub-groups and main groups. The index cards for each class title bear the list of titles and numbers of groups included. Index cards for groups bear the list of titles and numbers of unit numbers included. In Table IV, there will be noted parentheses (cf. —). These are cross index references. An example of cross indexing is as follows:

In Class 0, group 1–10 is "Organization" and title 2 is "local ordinances." Following this we have cross reference number 501–600. This refers us to Class V, Food and Sanitation, under which we find in group 511–520 Milk and Cream, unit number 516 "ordinances." We also find 526 referring to meat ordinances, 536 store ordinances, 546 restaurant ordinances and 556 other food handlers' ordinances. Note that in group V all unit numbers referring to ordinances end in the same digit "6."

It must further be noted that to make such an index practical, all titles consisting of more than one word should appear in the alphabetical index under the initial letter of each word, for example—Periodic Physical Examinations (309) should appear in the index under "P" and "E" and the title Diphtheria Prevention Clinics should appear alphabetically under "C," "D," and "P."

We have now been using this file for 2 years and find that it practically eliminates the personal equation in filing. When we begin to search for a letter about a given topic it makes little difference from what point of view we approach the subject. If it is about diphtheria we will find it alphabetically so indexed. If it is about diphtheria immunization it will be indexed under both diphtheria and immunization. If it is about educational publicity con-

cerning diphtheria immunization it will be indexed under diphtheria, immunization, education and publicity. The labor involved in keeping this system is small after the initial preparation. If it is carefully planned with a view to the needs of the particular department for which it is designed, few new titles will need to be added. By providing a space on the letter head for entering the file number and determining this number at the time of dictation, both filing and finding are quick and simple procedures. We do not yet see any need for transferring in the near future and it is quite possible that no transferring will be needed until 5 years have elapsed. Some of the titles are little used, and yet it is these very titles which will confuse a straight alphabetical subject file. The time consumed in filing our correspondence has not exceeded 30 minutes per day.

This system can be expanded indefinitely. If sub-titles are required for the unit titles they can be provided by using decimals, and this is frequently desirable for special files. It can also be extended beyond 1,000. In fact, we have so extended it by using the numbers above 1,000 to designate the pamphlet cases in which we file our journals and the publications of other organizations, such as city and state health departments, national organizations, cooperating local organizations and commercial agencies.

A complete outline of the system will be sent in response to requests for the cost of preparation, which is $.75 each, payable to the City Treasurer, Racine, Wis.—W. W. Bauer, M.D., Commissioner of Health, Racine, Wis.

Warwick Town, Rhode Island—Rhode Island in 1927 won the prize in connection with the health studies made by the Women's Federated Clubs. The prize consisted of a special health survey of Warwick, the town chosen by the state health commissioner, which was made by the Committee on Administrative Practice of the American Public Health Association, and was coöperated in by the American Child Health Association.

As a result of the survey, the town council decided to form a health unit with a full-time health officer, and at the financial town meeting in May, 1929, there was appropriated $10,000 for the establishment of a unit, to consist of a full-time health officer, 2 nurses and a sanitary inspector. The town council and the financial town meeting are to be commended for their action, but they should see to it that local politics and deferment of action do not prevent the speedy formation of a health unit, which would be a great asset to a rapidly growing urban community that has some special sanitary problems.—James Wallace, M.D., Associate Field Director, A. P. H. A., New York, N. Y.

Influenza Surveys—Realizing that influenza is an extremely poorly reported disease throughout the United States, and that morbidity reports could therefore not be expected to give a true picture of the actual incidence of the disease, the U. S. Public Health Service decided to carry on a nation-wide survey to determine with some degree of accuracy the real incidence of influenza and the frequency with which it was preceded by, associated with, or followed by, some other condition such as pneumonia, or a cold. The Detroit Department of Health has coöperated in this survey. In Detroit a house-to-house canvass was made in 20 representative districts which included visits to 6,700 homes. In all 18,056 individuals are included in the personal histories obtained but of this number only 17,814 gave sufficient complete information to be included in the survey.

The results of this survey covering the months of December, 1928, and

January, 1929, indicate that 23.9 per cent of the population suffered from one or another of the respiratory infections —colds, influenza or pneumonia. In all 13.2 per cent gave a history of influenza; 1.7 per cent had grippe; and 0.4 per cent suffered from pneumonia. The incidence of 23.9 per cent for the respiratory infections is appreciably lower than the incidence found in the U. S. Public Health Service survey for some of the western cities and slightly lower than most of the midwestern or eastern cities with the exception of Baltimore. The total number of cases of influenza, grippe, pneumonia and colds per 100 persons canvassed for the several communities was as follows: San Francisco, Calif., 34.1; Seattle, Wash., 30.9; Kansas City, Mo., 27.1; Farmington, Mo., 37.7; Des Moines, Ia., 47.1; New Orleans, La., 29.6; Cincinnati, O., 27.0; Pittsburgh, Pa., 25.2; Baltimore, Md., 15.1 (exclusive of colds not confining the patient to bed); Syracuse, N. Y., 26.8; Boston, Mass., 23.5. The average of all these localities except Baltimore and Detroit was 29.7.

Nearly 15 per cent of the population canvassed in all localities surveyed in 1929, except Detroit, gave a history of having suffered attacks of influenza or grippe, while 0.47 per cent gave a history of pneumonia. In Detroit the survey indicated that 14.9 per cent of the population canvassed suffered from influenza or grippe and 0.4 per cent had pneumonia.

If results of the survey reflect conditions in the city as a whole as they should—(1) A very insignificant percentage of the actual number of cases of influenza were reported, while approximately 36.3 per cent of the pneumonias were reported. (2) The average loss of time through suffering from one or another of the respiratory conditions was 8.2 days per individual, with an average of 3.6 days spent in bed per patient. Loss of time varied from 3.6 days with colds to 30 days for pneumonia. Days in bed varied from 1.5 in colds to 18 days in pneumonia. (3) Approximately 43 per cent of all patients secured the advice of a physician. Practically all pneumonias were attended by physicians while less than one-fourth of the colds obtained medical advice. In influenza 52 per cent were attended by physicians.—U. S. Public Health Service Release of July 6, 1929, and *City Health,* Detroit Department of Health, June, 1929.

Physical Examination of Indians —Several of the national health agencies, in coöperation with the Oregon health authorities, made possible the establishment of a diagnostic clinic on the Klamath Indian Reservation in Oregon. The examinations indicate that the average Indian of middle 20's is somewhat overweight, married, clean, well dressed, speaks English correctly, lives in a 4-room house, and there is a three to one chance that some member of his family is ill with tuberculosis. His teeth are unclean and decayed, and one out of five has impaired vision due to trachoma.—*Study of the Health of Indians on the Klamath Reservation in Oregon,* National Tuberculosis Assn., Feb. 1, 1929.

C. C. YOUNG

A PRACTICAL METHOD OF MEASURING SUNSHINE

FRED O. TONNEY, M. D., FELLOW A. P. H. A., AND PAUL P. SOMERS

Bureau of Laboratories and Research, Chicago Department of Health, Chicago, Ill.

AN improved actinic method of testing sunshine for ultra-violet light has recently been developed in the Research Laboratories of the Chicago Department of Health. It depends in principle on the decomposition of oxalic acid, previously studied by Anderson and Robinson.[1]

The detailed technic, which is simple and readily adaptable to field work, is described in a recent issue of the *Journal of Preventive Medicine.*[2] The apparatus is shown in Figure I.

As a result of correlation of the actinic readings of sunshine with the erythema reaction of untanned skin, the actinic reading yields information as to the presence in appreciable amounts of the physiologically important shorter ultra-violet waves, which are cut out by obscuring factors such as smoke, dust, mist and window glass, and which also vary in intensity with the angle of incidence of the sun's rays to the earth's surface. A reading of 3.53 to 3.72 mg. of oxalic acid by the technic used correlates approximately with the minimal erythema dose of sunshine.

By the method described it is possible for those interested in the health value of sunshine to obtain comparative data on the intensity of solar ultra-violet light in any locality—by hours, months and seasons.

In Chicago it was found that there were 7 months of low ultra-violet values in sunshine and that during most of this period the ultra-violet light inten-

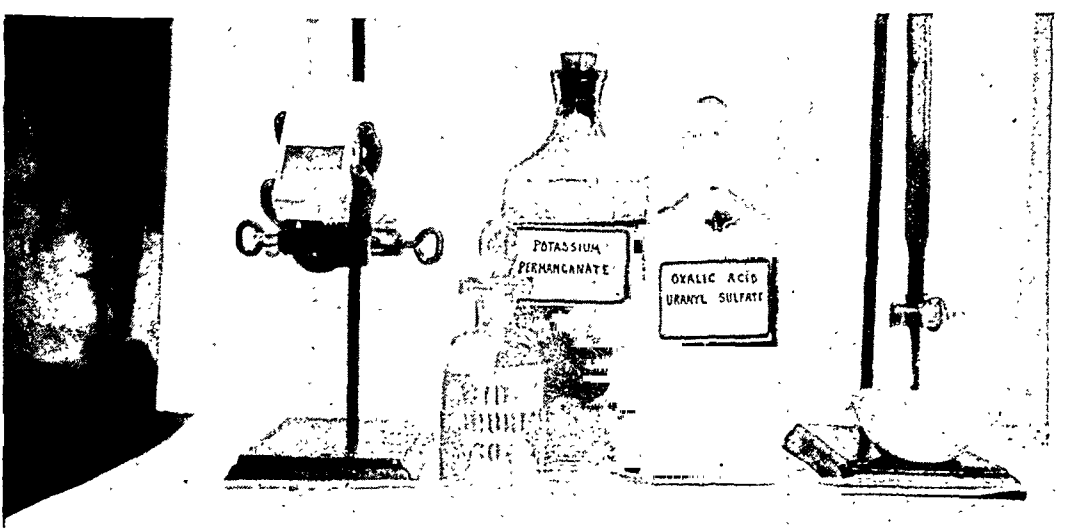

FIGURE I

sity, as judged by the erythema dose, was too low to afford a satisfactory dosage in hourly periods of exposure.

One of the difficulties encountered in the field use of the actinic method in cold weather is the fact that when the solutions freeze even slightly, the sensitiveness of the reagents to light is reduced. During freezing weather, therefore, the readings were heretofore taken indoors through an open window.

Further work on the practical use of the actinic method out-of-doors in freezing weather, indicates that ammonium sulphate can be used to prevent freezing of the solutions without decreasing the sensitiveness of the reagents to light. A 40 per cent solution of the ammonium salt in the actinic reagent prevented freezing down to 4° F. and did not interfere with the reaction. This temperature was the lowest encountered during the experiments and therefore does not represent the lower limit of accuracy of the method. In the titration, a slight correction factor, based on a "blank" control on the actinic-ammonium salt mixture, is desirable in order to check against reduction of the permanganate solution by the unexposed reagents. Salts of sodium could not be used as anti-freezing agents because of their interference with the actinic response. Additional work on this phase of the technic is being done.

A METHOD FOR DETERMINING PRESENCE IN MILK OF AGGLUTININS FOR BRUCELLA ABORTUS

A. G. LONG, M. D., FELLOW A. P. H. A.

Director, Laboratory, Maine State Department of Health, Augusta, Me.

PUT about 20 c.c. of herd milk, or milk from individual cows, in clean test tubes of large diameter, and set in the incubator over night. If souring is not complete in the morning or the whey is not clear, add not more than 0.5 c.c. 50 per cent acetic acid to the tube, shake well and filter. The whey for the test should be quite clear or, at most, faintly opalescent. Colostrum is unsuitable.

To set up the test—Use at least 4 ordinary Wassermann tubes for each test. In the front tube place 0.9 c.c. normal salt solution and 0.5 c.c. in each of the other back tubes. Add 0.1 c.c. of whey to the front tube. Mix well. Transfer 0.5 c.c. to the next tube behind. Mix well. Treat the other tubes the same, discarding the final 0.5 c.c.

When dilutions have all been made, add to all tubes 0.5 c.c. of *Brucella abortus* antigen of such concentration that this final dilution gives an opacity equivalent to 1–1,000 (silica standard of the A. P. H. A.).

Tubes are then placed in the water bath at 37° C. for 2 hours, and read the next day after standing at room temperature over night. Positive tubes give heavy precipitates with clear supernatant fluid. On shaking this, precipitate should break into coarse clumps. Unless clumping is present in the first three tubes the reading is reported as negative.

Dilutions are 1–20; 1–40; 1–80; 1–160; etc.

We have found the blood and milk check very satisfactorily.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Insulin and Diabetes—For the first 3 months of 1929 the death rate from diabetes among industrial policy holders of the Metropolitan Life Insurance Company was 23.8 per 100,000, the highest diabetes rate ever recorded for this group. The course of the diabetes death rate among insured males shows that between 45 and 65 years there has been a distinct and significant rise. For females, the only ages showing a decline have been those of childhood and early adult life. From 35 to 45 years of age there has been a slight rise, and after age 55 the female death rate has risen sharply.

A survey of 1,044 fatal cases on which the Metropolitan has paid claims, during the early part of 1929, shows that up to April 15, 63 per cent of the cases received insulin. In a similar survey made in 1924–1925 only 49 per cent of 1,800 cases were given insulin. The percentage of fatal cases treated with insulin was higher in 1929 than in 1925 except in the younger age groups. Between the ages 15 and 44, the percentage of cases treated during 1929 was 84, as compared with 71 in 1924–1925; at ages 45 to 64, 66 per cent as against 52 in the earlier series; and at 65 years and over, 49 per cent in 1929, as against 32 per cent in 1924–1925. At ages under 15, there was no distinct difference between the two series, the percentage treated in each being approximately 70 per cent. The increased use of insulin has resulted in a decline in the incidence of deaths from coma. In 1929 coma was present in 41 per cent of the 1,044 cases. In the earlier series, 48 per cent died in coma. Seventy-three per cent of the coma cases received insulin during 1929, compared with less than 60 per cent in the earlier series. Degenerative conditions such as heart, kidney and circulatory diseases were present in over 60 per cent of the 985 cases in which diabetes was the primary cause of death. Since these diseases occur chiefly after 60 years of age, they form another index of the improvement of diabetes with insulin.—*Stat. Bull.*, Met. Life Ins. Co., 10: 3–6 (May), 1929.

Peptic Ulcer and Cancer of the Stomach—There is a great difference of opinion as to the number of cases of cancer of the stomach due to peptic ulcer. According to several estimates the incidence varies from about 2 per cent to more than 60 per cent. One physician reports that 30 per cent of all ulcers of the pyloric end of the stomach which were resected proved to be undergoing cancerous degeneration. Another states that 26 per cent of gastric ulcers, in all parts of the stomach, were undergoing cancerous degeneration. Three cases were reported in which there were symptoms of gastric peptic ulcer extending over a number of years and which proved to be cancerous. In 1 patient, with symptoms for 12 years, an adenocarcinoma was in the margin of the ulcer. In 2 others, carcinoma was found in the base of the ulcer. In 1 case the clinical symptoms of peptic ulcer had existed for 5 years, and in the other for 30 years.

In 1926, cancer of all organs caused 99,833 deaths in the U. S. Registration Area. There were 35,694 deaths from

cancer of the stomach and liver. Cancer originating in the stomach probably accounts for one-third of all the deaths from cancer in the United States. It can be conservatively estimated that at least one-fifth of the cases of cancer of the stomach arise from peptic ulcer. If removal of so-called precancerous lesions elsewhere in the body is good policy, this should eminently be a proper procedure in ulcers of the stomach that do not respond readily to competent medical treatment.—J. S. Harsley, *J. A. M. A.*, 92: 1813–1816 (June 1), 1929.

The Menace of Appendicitis—For the 5-year periods up to 1920 the appendicitis death rates in England were 50, 62, 69 and 67, respectively, per million population. From 1918 to 1927 both the total number of deaths and death rates showed a continued increase. In 1918 the appendicitis death rate was 65, as compared with rates of 64 for hernia and 81 for intestinal obstruction. In 1927 the appendicitis rate was 70 as compared with 50 for hernia and 65 for intestinal obstruction. A review of deaths from "acute abdomen" at the Leeds General Infirmary, for 1924 and 1925, includes 1,080 cases of acute appendicitis with a death rate of 5.7 per cent. About one-half of these were uncomplicated by abscess or general peritonitis. An analysis of a series of 2,252 cases of appendicitis shows 135 uncomplicated by peritonitis, with no deaths; 913 internal operations, with 3 deaths; and 95 cases with diffuse peritonitis, with 28 deaths. An analysis was made of 2,018 cases occurring over a period of 5 years at London, St. Thomas's and Manchester Royal Hospitals. The average total death rate following immediate operation was 6.7 per cent, rising at St. Thomas's to 8.4 per cent. Among 206 cases of appendicitis operated on at the Great Western Railway Hospital, there were no deaths. Eighteen per cent of the cases required drainage. It becomes increasingly evident that a reduction in mortality will only be effected by greater precision in diagnosis, earlier operation, and standardization of technic.—H. H. Greenwood, *Lancet*, 1: 973–975 (May 11), 1929.

Immunization against Diphtheria—Diphtheria toxoid employed in 3 doses immunized 94 per cent of 100 susceptible persons to the point of a negative Schick test, as compared with 5 doses of toxin-antitoxin which immunized 100 persons to a negative Schick test. The results with both preparations were good, especially since the majority of persons in the series were adults, who are more difficult to immunize than children. The fact that the series given toxoid included children, while those given toxin-antitoxin included no one under 17 years of age, does not account for the difference in results. Exclusive of children, 93.3 per cent in the series given toxoid were completely immunized. In this series no serious reaction occurred with either the toxoid or the toxin-antitoxin. In the series of 100 susceptible persons who were given 3 doses of toxoid and were retested, together with 44 persons who received less than 3 doses and were not retested, 24.3 per cent showed no reaction. A small local reaction was shown after 1 or more doses in 31.9 per cent of the 144 cases; a slight general reaction in 28.5 per cent; and a moderate to severe general reaction in 6.3 per cent. In 5 of the 9 cases in which the more severe reactions occurred, there was a marked "pseudoreaction" in the original Schick test. In 1 other there was a moderate "pseudoreaction"; in 2, a history of a previous attack of diphtheria, and in another there had been repeated exposures to the disease.

Diphtheria toxoid is a better immunizing agent than diphtheria toxin-antitoxin mixtures, even when 5 doses of the latter are given. Diphtheria

toxoid may safely be employed in immunizing adults, and an extra skin test to detect sensitization to the bacterial proteins in the toxoid is not necessary. Care should be taken that the broth employed in producing the toxoid does not contain an excessive amount of protein. —G. J. and G. H. Dick, *J. A. M. A.*, 92: 1901–1903 (June 8), 1929.

Maternal Mortality—Deaths from all puerperal causes in the period 1915 to 1925 numbered 15,876 in New York State. This gave a death rate of 5.9 per 1,000 total births for the period. The average annual rate in 1915–1920, exclusive of 1918 (the year of the influenza epidemic when mortality from puerperal causes was abnormally high), was 5.7 per 1,000 births. The average annual rate in 1921–1925 was also 5.7. In 1921–1925 in the urban part of the state, mortality from puerperal septicemia was 1.3 per cent higher than for the preceding 5 years (exclusive of 1918), and 8.6 per cent higher from other puerperal causes. In rural New York the mortality from puerperal septicemia declined 23.9 and mortality from all other puerperal causes 27.3 per cent.

As a result of a study made in 1925 of 696 maternal deaths in upstate New York, it was found that 74 per cent had received hospital care. Of 230 cases, 13 per cent had entered the hospital before the beginning of labor; 37 per cent entered during labor; and 50 per cent were brought in after delivery. Only 16 cases were reported as having been delivered by a midwife, but 11 others had a midwife in attendance at some time. Sixty-five per cent of 408 cases had prenatal care. It was found that 34 per cent did not have prenatal supervision until the 7th, 8th or 9th month. Puerperal sepsis accounted for 37 per cent of the deaths; albuminuria and the toxemias for 21 per cent; and hemorrhage for 9 per cent. Thirty-eight per cent of the deaths were involved with operative procedures. Hemorrhage was involved in 17.5 per cent of the deaths, 67 being prenatal and 58 postnatal hemorrhages. This study shows the large proportion of maternal deaths caused by septic poisoning and the large number of cases in which operative procedures were involved. It seems that one of the chief causes of excessive maternal deaths is the increasing tendency to interfere with physiological processes. This is more prevalent among city practitioners and in hospital practice than among rural practitioners.—Matthias Nicoll, Jr., *New York State J. Med.*, 29: 800–802 (July 1), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

TYPHOID FEVER OUTBREAK IN FORT WAYNE, IND., DUE TO DUAL VALVE CONNECTION

RUTH C. STURTEVANT

Bacteriologist, Board of Health, Fort Wayne, Ind.

ON February 26, 1929, people living in the vicinity of the Wabash Railroad at Fort Wayne, Ind., complained to the Health Department of dirty water. An inspector was immediately sent to the locality and he reported that the increased turbidity was probably due to the fact that there had been a fire in the neighborhood. This report was corroborated by the head of the water works and the explanation was accepted. A water sample taken there on that date showed *B. coli* in 0.1 c.c. samples. On February 27, several samples of water were taken in that neighborhood, following continued complaints. Physicians were mentioning innumerable cases of dysentery (although none were actually reported), and on March 1 a drastic water sampling and engineering investigation began.

A dual valve was discovered, owned and operated by the Wabash Railroad. This permitted the use of either river water or city water. The valve had been left open, allowing the city mains to become loaded with river water. The valve was immediately closed, photographed, and ordered discontinued. Five days later it was still in place, although we hope not in use, after which it was eliminated.

Gastrointestinal symptoms broke out in another part of the city and it was found that the reservoir had become contaminated with the river water. It was promptly drained and cleaned. By March 8 the water contamination was completely cleared up, as shown by samples taken from places where previously contamination had been demonstrated.

We have no way of knowing the number of cases of gastroenteritis, but there were many. Onset was from 12 to 24 hours after drinking the water and the victims were acutely ill from 3 days to a week with intense diarrhea, vomiting, pain, and extreme weakness. On March 22 the first typhoid fever cases were reported. There were 53 cases and 3 deaths. The last case was reported on May 11. All cases were traceable to the condition of the water.

Despite the fact that in January, 1924, the Indiana State Board of Health adopted and ordered promulgated, effective June 1, 1924, the rule abolishing all such connections, this one had been in constant use since then. In 1923 this same type of valve connection on the Pennsylvania Railroad property caused a similar outbreak with 147 cases and 20 deaths. At this time, a city-wide search was made for other valves and all were ordered out. The search has been resumed during this outbreak and many such valves have been located, although they were not in use. They have been eliminated.

The Process of Aeration in Iron Removal from Water—In general, closed tanks for iron removal are more satisfactory, smaller and cheaper than open tanks, except that, in a closed tank, it is difficult to get rid of the excess of oxygen, which remains absorbed in the water owing to the pressure of the pump. This oxygen corrodes the iron pipes in the distributing system for the water supply, and completely nullifies the effect of the iron removal plant. An apparatus is described, which eliminates this danger, if it is inserted at some point between the reservoir and the pump. It consists of two shafts, with a communicating passage in the lower half of the central wall, into one of which the syphon pipe bringing the supply enters, and out of the second of which the exit pipe leads. The aeration apparatus is built between the two, consisting of three pipes, an injector for water and compressed air, a vertical pipe enclosing the lower half of the injector, and a syphon hood, passing from one shaft to the other. Water containing the necessary compressed air is forced down the injector; it rises up, the vertical pipe mixing thoroughly with the water entering through the syphon pipe, bringing about the separation of the iron. The air and excess oxygen are drawn out of the syphon hood by means of a suction pump. The circulation set up by the compression and suction not only removes the air, but creates an energetic stirring, causing the iron to form a floc, which is easily filtered. Three times the calculated amount of required oxygen is added, i.e., for 100 litres per second with 20 mg. Fe 1 litre per second of air at atmospheric pressure is added. Three plants for iron removal, with this arrangement for aeration, are described, which can be inserted in the supply system. In each, the water is raised 1 to 2 meters above the water surface and let fall through the compressed air injector to the bottom of the removal tank. The water and air rise in the vertical pipe, which is many times wider than the injector. The water is circulated several times in this vertical pipe and the circulation chamber, insuring complete iron removal and development of a good floc. The greater part of the floc settles down into hanging rods or into the rinsing pipe, so that only a small quantity enters the filter.

In one plant described, for inserting near the source of the water supply, the water in the vertical pipe and the circulation chamber circulates about 28 times. Wood-shavings below, and clean, evenly grained gravel above, are used as packing for the filters in these iron removal plants.—A. Vogt, *Tech. Gemeindeblatt*, 32: 6, 1929 (from papers of Water Pollution Research Board, England).

Sterilization of Sea Water by Ozone and Its Use in the Purification of Contaminated Shellfish—Ozone passed through an artificially prepared sea water containing mineral halides had no action on chlorides and bromides but liberated iodine from iodides. It was found that surface sea water (down to a depth of about 100 meters) gave no free iodine upon ozonization, the iodine in the upper strata being in the form of stable organic iodides. Sea water containing heavy suspensions of infectious microörganisms was sterilized in 8 minutes. Sea water ozonized for double the period necessary for sterilization, aerated free from ozone, re-inoculated with microorganisms and incubated for 18 hours gave an abundance of microörganisms, indicating that the water contained no bactericide, and was harmless to shellfish.

Contaminated shellfish in a sterile water undergo progressive self purification, ejecting organisms until the pulp itself becomes sterile. This purification takes several days, varying with condi-

tions. Oysters were immersed for a much longer period than was needed for self purification in changes of sea water ozonized for twice the period necessary for sterilization. These oysters were compared with another batch treated under the same conditions but without ozonization of the water. No difference in appearance, constitution and flavor could be detected. The process can be worked by a rapid sand filtration of sea water, ozonization followed by aeration to eliminate the excess ozone and allowing it to flow continuously over oysters in a trough at a rate of about 100 c.c. per hour per oyster.—H. Violle, *Rev. d'hyg.*, 51: 42, 1929 (from papers of Water Pollution Research Board, England).

Recovery of Tin from the Effluents Derived from the Process of Weighting Silk—In weighting silk, the silk fibers are soaked in a stannic chloride solution, and washed in quantities of water to remove the precipitated tin and the excess chloride. The washing water contains about a third of the tin employed. At present the method employed for recovering the tin is long and costly. The washing water is further diluted to precipitate the greater part of the tin by hydrolysis and neutralized by passing over limestone. The effluent, only partly neutralized, corrodes the channels and pumps and causes the dried oxide to contain impurities, iron and silica which decrease its value. Settlement takes place in a tank, into which the effluent continuously enters, but the sludge is only removed occasionally. The sludge is pumped into a storage tank and then into a filter press, where its water content is reduced.

The filter press is dried later in an oven or drying drum, but the process is long because a skin forms over the oxide, preventing the evaporation of the water. This process is not only long, but 16–75 p.p.m. of tin pass out with the effluent, and more is lost during the pumping process.

Gibson Buttfield of the Vulcan Detinning Company, after a thorough investigation of this process, has invented a new method which is being used with complete success at the works of the Textile Dyeing Company of America, Inc., at Hawthorne, N. J. The washing water, containing tin, is neutralized by an automatically continuous dose of lime-sludge, which precipitates practically all the tin. The coagulated tin-oxide is separated in a Dorr-thickener, continuously pumped into a storage tank and passed on to a spray dryer. Here it dries rapidly and is automatically packed in export casks or sacks. The lime sludge is prepared in a tank with a stirring apparatus. The precipitated oxide is led through a series of resistance plants to remove air bubbles and prevent the floc floating in the thickener.

The spray dryer is made by the Industrial Associates Inc., in New York. This process is very satisfactory, because the loss of tin is only about 4 p.p.m. of effluent, the cost of drying is 50 per cent and the total costs only about third of the old process, and the oxide obtained is cleaner and of a greater value.—*Chem. Ztg.*, 52: 925, 1928 (from papers of Water Pollution Research Board, England).

Disinfection of Swimming Baths in the Tropics with Chlorine and Chloramine—Experiments on the chlorination of the water with chlorine gas, hypochlorite, and chloramine, in two open air swimming pools of the tropics in the municipality of Batavia are cited.

Owing to the strong catalytic action of sunlight in decomposing hypochlorite it was found impossible to keep a fixed minimum residual chlorine in the water of swimming pools with tropical conditions. Disinfection with hypochlorite

could, however, be obtained by distribution at the inlet, at the middle of the tank, and at the outlet; and the adjustment of the amount added, 6 mg. per lit. during the day and 2 mg. per lit. during the night.

The decomposition in sunlight of chloramine was much less, but because of its weaker disinfecting power a sufficiently great minimum quantity of chloramine was needed. In practice, in Batavia good results were obtained with a residual content of 0.4 mg. per lit. of active chlorine as NH_2Cl. Bacteriologically, disinfection with chloramine appeared to give better results.—K. Holwerda, *Mededeelingen Van Den Dienst Der Volksgezondheid in Nederlandsch-Indie,* Vol. 17, 1928, Part II, Foreign Edition, pp. 357–382. Abstr. H. R. Crohurst.

The Effect of Improved Road Surfaces on Public Health—The improvement of public health by hard surfacing of roads has seldom received attention. Some of the factors that assist in this are: (1) Hard surface roads have removed the ever-present dust in dry weather and mud in wet weather which caused injurious effects to both travelers and persons living along the roads. Roads are more easily cleaned and washed, thus removing the collections of liquid and solid animal excreta which were blown into the air with the dust on the former dirt roads; (2) medical men are able to get to their patients more often with less time, and patients may be taken to hospitals with less discomfort in shorter time; (3) food products in fresh condition can be distributed more readily.—W. Lionel Jenkins, *Surveyor,* 74, 1904: 67 (July 20), 1928. Abstr. D. W. Evans.

An Outbreak of Typhoid Fever Traced to Corned Beef Infected by a Carrier—An account of an epidemic of typhoid fever at Wakefield, Mass., a town of about 17,000 population. The place of infection was traced to a church supper, and out of 97 individuals found to have attended the supper, 16 became infected with typhoid fever.

Two tables are given which contain such information as the food eaten by the 15 sick and 49 well individuals for whom this information is available, with the per cent eating each food, the difference in per cent between the number of sick and well individuals who ate each food, and the standard deviation of the differences. The accumulated evidence pointed to corned beef as the mode of infection.

The meat was prepared by 4 women at their respective homes. The only one giving a positive Widal stated that she had had typhoid fever 17 years before. A fecal specimen from this person was positive for *B. typhosus* although her health was excellent at the time of the supper and thereafter. This woman prepared about 20 per cent of the corned beef eaten at the supper, which agrees with the fact that about 15 per cent of the guests became ill.—Clarence L. Scamman and Filip C. Forsbeck, *New England J. Med.,* 199, 14: 664–665 (Oct. 4), 1928. Abstr. F. J. Moss.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Poisoning from Commercial Methyl Chloride—Among the several gaseous substances of more or less toxic nature which recent developments of mechanical methods of refrigeration have brought into usage, are sulphur dioxide, ethyl chloride and methyl chloride. The scientific staff of the Chicago School of Sanitary Instruction has been investigating refrigerant gases for the past 11 months, and intensively for the past 4 months. In the past year there have been reported in Chicago 25 cases of poisoning by commercial methyl chloride gas, with 7 deaths. All except 3 cases (which occurred in a manufacturing plant where methyl chloride refrigerators were made) developed in kitchenette apartments from leaks in the refrigerating system.

The first 4 cases, of which 3 were fatal, occurred in August, 1928. The next 3 cases were first reported as botulism. The next 2 cases, a man and wife, were of less severe type. Then 3 cases were reported in the manufacturing plant above referred to where the illness was characterized by drowsiness and nervous symptoms. Early in June, 1929, 7 cases of uncertain origin were reported in one family and 3 of these died; in the latter part of the same month 3 more cases were reported, with 1 death. Food poisoning was the tentative diagnosis in practically all cases at first; then, later, strychnine, metallic poisoning and mushroom poisoning were suspected in some.

The chief symptoms recorded were drowsiness, mental confusion, stupor, weakness, nausea, pains in the abdomen, and vomiting. In the more severe cases there were convulsions and cyanosis, alternating with coma; later, delirium and restlessness. In some instances the patients were aroused from their stupor by attacks of vomiting. On account of their mental disturbance, several were referred to psychiatrists for diagnosis. Four of the patients complained of blurring of vision and vertigo, which persisted after they had otherwise clinically recovered.

Among the chief physical findings, the pupils in practically all cases were widely dilated and reacted sluggishly to light, while in a few instances a slight squint and unsteadiness of the eyeballs was noted. The pulse, in adults, went as high as 150, and in children reached 165. The respiratory rate in adults reached 32 and in one child was 56. About 36 hours after exposure to methyl chloride, there generally occurred a rise in temperature, reaching as high as 103.5, and in 2 cases just before death it was 107. In nearly all cases there was suppression of urine, which sometimes lasted 48 hours. Urinary specimens tested showed acetone, and formates were found in the 2 specimens for which it was tested (acute stages), while occasional albumin, red and white blood cells were found. Coma in some cases lasted to 72 hours, with recovery. Death in every case was preceded by severe convulsions, tonic in character, and accompanied by a profound cyanosis followed apparently by respiratory paralysis. The blood picture was suggestive of a pernicious anemia ranging from 56 to 85 per cent hemoglobin, with the white count averaging 16,000 on the 3d day.

"The diagnosis is based upon the symptoms and the physical findings

previously noted, together with the presence of formates and acetone in the urine and a history of exposure to the gas." The breath has a musty, sweet odor, and there is an odor of acetone about the patient. A gradual onset of 2 days or more, with drowsiness and mental confusion, is an outstanding syndrome. The spinal fluid was under increased pressure in the 2 cases tested, while the blood pressure was significantly lowered in several of the cases. Examination of the stools failed to show blood in 3 cases.

The poisoning must be differentiated from botulism, poisoning by strychnine, wood alcohol, grain alcohol, and heavy metals, and from sleeping sickness (encephalitis lethargica).

The treatment consists of immediate removal of the patient to a hospital, and giving of alkalies. Oxygen inhalations should be given from the start and continued until the peculiar odor of the breath and body has cleared up. Under no conditions should chloroform or chloral be given. The balance of the treatment is symptomatic.

Upon post-mortem examinations, the surface of the bodies revealed nothing unusual, but muscles and blood were of a dark red color resembling that seen in carbon monoxide poisoning. The lungs showed edema and passive congestion; the kidneys, liver, and spleen—cloudy swelling; the stomach—marked hyperemia and even pinpoint hemorrhages; and the brain—intense hyperemia, with softening, and, in 1 case, a small clot.

Chemical examinations of the tissues failed to show the presence of methyl chloride, carbon monoxide, heavy metals or alkaloidal poisons in any instance. It was not anticipated that methyl chloride would be found because of its low boiling point and rapid oxidation.—*Chicago's Health* (edited by Arnold H. Kegel, Commissioner), 23, 15: 90–95 (dated *April* but issued *July 18*), 1929.

ABSTRACTOR'S COMMENTS: These are additional impressions gained while a member of two Coroner's Juries, the first called by County Coroner, Dr. Herman N. Bundesen, to consider the June 30 death of a young married woman living in an apartment hotel on the North Side (her husband and mother narrowly escaped with their lives), and the second likewise called by Coroner Bundesen to determine the cause of death of a father, mother and small baby which took place July 16 in another apartment hotel on the South Side (not included in the above abstract).

The members of the first jury were: Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*, Foreman; Dr. H. Gideon Wells, Head of the Department of Pathology at the University of Chicago; Prof. F. C. Koch, Head of the Department of Physiological Chemistry there; Prof. Morris S. Kharasch, Acting Head of Department of Chemistry at the same university; Dr. R. H. Jaffe, Director of the Pathological Institute at Cook County Hospital; and the writer.

In the second jury, Dr. Wells acted as Foreman while Dr. William I. Fishbein, Physician in Charge of the Laboratory School of the University of Chicago, and Dr. Russel M. Wilder, Professor of Medicine at the university, took the places of Dr. Morris Fishbein and Dr. Jaffe of the first jury at the first hearing. At the second and final hearing, Dr. Morris Fishbein again acted in his own stead.

The juries inspected the apartments in both instances. The apartments had a weather exposure only on one side, and the three windows in each case were said to have been found wide open when the first help arrived, although the shades were half drawn in the second mishap. Both apartments were located on the fifth floor and not obstructed by

nearby buildings. There was, however, no cross ventilation. The weather was hot on both occasions. Exposure was 40–48 hours for 2 of the patients and about 24 for the other in the first mishap; but the 3 deaths in the second mishap took place after an exposure of not over 20 hours, and probably between 11 P.M. and 6 A.M.

Both vomitus and fecal matter stained the beds. The air had a sweet, musty odor which seemed more pronounced in the tiny kitchens where the iceboxes were located, although the methyl chloride contents of both boxes had been drained some hours before we arrived. Its presence in the air was still easily detectable by the green-blue flame of the Bunsen burner after the flame had passed through a small piece of copper gauze, and in both instances the flame increased in size and brilliancy when the icebox was approached. In the second mishap several gold fish in two small glass aquariums were alive and apparently unharmed, but the water, upon testing later in Prof. Kharasch's laboratory, showed it had absorbed a large amount of chloride. A mouse was found dead under the dining room table in this apartment.

In both instances some 50–100 icebox units in as many apartments had been hooked up to one methyl chloride storage tank located in the basement in which a pressure of about 100 lb. was maintained by an automatic pump, so that a leak in one unit might drain practically the whole system. The defrosting was left to the janitors, and was attended to about every 10 days. While all units and connections were claimed to have been tested repeatedly under high pressures before occupancy of apartments, it was suggested that if de-frosting were not frequent enough, coats of ice thickening on the coils in an icebox might spring the coils until a leak occurred, or a joint might leak. Service men testified that the only test they made for leaks was with lather made from shaving soap and applied with a brush, but admitted that they could not reach all parts of coils, etc., with same. It was stated also that some of the unions between the coil units and supply pipes in the iceboxes had proved defective.

While icebox manufacturers had had mishaps in which large quantities of the gas had occasionally escaped, and workmen had suffered and sometimes had been off for as long as 2 weeks, nothing serious had happened and it was not thought domestic exposures would ever approach these in magnitude. No previous research upon the matter had, however, been made, and most thought that small amounts even over a prolonged period were harmless.

Testimony showed that a similar mishap had occurred in the North Side apartment hotel on the first floor some 6 weeks previously, in which the husband had been found unconscious, taken to a hospital, and later removed to the county psychopathic hospital for restraint and care, for several days. Service men of the company concerned had examined the icebox at that time and pronounced it intact.

Dr. Ralph W. Webster, toxicologist for the county, testified that he found methyl chloride in the food left in the icebox in the first mishap, and found formaldehyde and formates in the organs of the woman who had died, and that two guinea pigs left in the apartment likewise showed formaldehyde and formates in their tissues; also that two other guinea pigs had died after an exposure of about 30–40 hours. Examination of the organs of the 3 victims in the second mishap showed methyl alcohol, formaldehyde, and formates, while the blood showed an excess of chlorides.

The *Journal of the American Medical Association,* July 27, 1929, page 312, published a list of 35 trade names of mechanical refrigerators and refriger-

ants used, so far as is now known; of these, 8 were using methyl chloride. In the July, 1929, issue of this JOURNAL, page 825, we called attention to *Public Health Bulletin 185,* which discusses experimental toxicity of methyl chloride and related substances. A comprehensive article with case reports by Kegel, McNally, and Pope is contained in the August 3, 1929, issue of the *J. A. M. A.,* pages 353–358.

It is probable that following the reported banning of the use of methyl chloride in iceboxes in Chicago by the Health Commissioner, something will be found to add to it in the way of an odor and an irritant to render its presence noticeable in the case of leaks. It was said there were 75,000 installations of methyl chloride iceboxes in Chicago alone; also that manufacturers were especially interested in stopping leaks of the substance because it was an expensive chemical. The prospects also seem to indicate that a non-toxic refrigerant has now been discovered.

Sequelae are occurring in some of the more severe cases, such as unsteadiness of gait, tremor, visual disturbances, weakness, insomnia and lapses of memory.—EMERY R. HAYHURST.

Progress in Metal Mine Ventilation—The recent occurrence of a number of deaths from heat stroke in the deep gold mines of South Africa, in a practically saturated atmosphere with temperatures between 85° and 91° F., calls attention to the fact that such temperature and humidity conditions are to be found in a considerable number of deep metal mines of the United States. While in Australia ice has been used for cooling mine air, the most effective remedy is the continual circulation of large volumes of fresh pure air from the surface. This also greatly dilutes the dustiness because of which there is now much silicosis as well as kindred diseases. Most certainly other dusts than silica are harmful, as has recently been pointed out by the U. S. Public Health Service in the investigation of the dust associated with cement working.

Metal mines are likewise subject to fires, and occasionally there have been carbon monoxide mishaps due to the burning of a small amount of combustible matter such as the debris from boxes, sawdust, etc.—D. Harrington, *Information Circular 6136,* U. S. Bureau of Mines, Washington, D. C., 1929.

Bureau of Industrial Hygiene in the Michigan Department of Health—The bureau was officially established April 1, 1929. A survey has already been made of a number of industrial health departments in the state and others will be made. A number of definite objectives have been formulated for the work of the Division and a physician who has had considerable experience with the department as well as in industrial medical work has been placed in charge of the bureau. Thus far, about 100 establishments have been surveyed ranging from 150 to 30,000 employees.—*Bull. Am. Ass. Indust. Phys. & Surg.,* III, 3: 3–5 (June), 1929.

International Conference on Silicosis—The Chamber of Mines of Transvaal, South Africa, has donated 2,000 pounds to the International Labor Office for defraying the expenses of an international conference of experts on silicosis, at Johannesburg in 1930.

Experts from Great Britain, the United States, Canada, Germany, Australia, and South Africa will discuss medical aspects of silicosis with especial reference to its control and prevention in mines.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Permissible Content of Arsenic in Food—This article includes observations made by the author as a result of a resolution of the association of canton and city chemists held in Geneva, June 7, 1929. The permissible limits for arsenic in food are considered: first, those additions which are intentional and, second, those which are unintentional. The first is subdivided into two headings: the intentional addition of arsenic to food, and the natural or accidental contamination of food with arsenic.

The association was unanimous in declining to recognize the deliberate addition of arsenic to food. Arsenic can always be determined in plant and animal organs. Sea water as well as water from springs or streams contains arsenic; it is in the soil, even in primeval rock (0.06 mg. per 100 gm. in granite, 0.4 to 1.3 mg. in marl, and 0.25 to 0.5 mg. in virgin soil of the United States). The highest amount actually occurring in plants is in wild oats and beets—0.062 mg., 0.061 mg.—and in tobacco 1.02 mg. per 100 gm. of dry substance. This arsenic is absorbed through the roots, experiments showing that arsenic spray on the leaves of the *Beta vulgaris* is not absorbed through the leaves. These amounts are not dangerous and need give no concern unless it should eventually be found that such minute amounts play a rôle similar to the vitamins in nutrition.

With the unintentional, especially undesirable additions of arsenic occur higher figures, (1) through the use of fertilizers, (2) through spraying (arsenic distributed in the ground may be absorbed by the roots and contaminate vegetables planted therein), (3) especially through the spraying of fruit itself. Under (1) and (3) the arsenic is absorbed in the plant and cannot be removed; under (2) there is a possibility of reducing the arsenic content by (a) limiting spraying to only immediately after blossoming, (b) more or less by rainfall, (c) by dipping the fruit 5 minutes in 0.3 to 0.5 per cent hydrochloric acid followed by a water rinse and (d) with fresh apples and pears by peeling (in fruits such as plums, prunes, berries, dried fruits, and preserves, the latter is not feasible).

Arsenic is detected in the skin, hair, feathers, bones, and internal organs of animals, and it is pointed out that while the maximum dose is from 5 to 15 mg. a noticeable effect follows the administering of 0.10 mg. There is a discussion as to the effect of arsenic on the organism. Pentavalent arsenic is nontoxic but easily reduced to the trivalent toxic form. Idiosyncrasy toward arsenic is not unusual and for that reason significant.

Comparison is made between arsenic in small and large doses; the former prevents oxidation although it accelerates growth and effects an interchange of metabolic process and apparently increases the formation of red blood corpuscles. A large dose is followed by loss of weight and increased decomposition of the elementary tissues, corresponding interference with the organic functions, breaking down of red corpuscles and fatty degeneration of organs. Owing to individual idiosyncrasies and variation in resistance it is

difficult to draw a line between large and small doses.

The chronic effect of arsenic is significant, especially on those organs most in demand for life processes, the kidneys, liver, capillaries and blood. Various amounts of arsenic are recorded in food, from undetectable amounts to as much as 1.854 mg. on one apple.

The author is compelled to register objection to the introduction in commerce of heavily sprayed fruit and is led to believe that the limit of arsenic permitted in England on apples—1.43 mg. per kg.—is entirely too high. In view of the fact that arsenic in small doses in foods shows definite and undesirable effects, that idiosyncrasy toward it is not unusual and on account of the continually increasing fad for raw food the following proposal is made:

That the highest permissible content of arsenic in food and food substances should not exceed 0.1 mg. of arsenic per kg. Exception is made for certain arsenic bearing natural mineral waters on the ground that they are dispensed as medicines and not as articles of food. —Prof. Dr. E. Waser, *Mitt. Leben. und Hyg.*, Band 20, Heft 3, p. 147, 1929.

The Loss of Iodine and Other Mineral Substances in Spinach, Resulting from the Customary Culinary Preparations—In this experiment the customary culinary operations were followed, in that tap water and added salt were used in place of distilled water as was the case with previous investigators. Summer spinach was washed free from sand and dried at 60° F. and ground in a mortar to a uniform powder. This was analyzed and the results are given. Picked and washed spinach was added in small portions to boiling tap water containing common salt. As the water continued to boil, the spinach was kept under the surface. After cooking, the water was removed, the spinach washed, and the liquids dried at 100° F. The residue was analyzed and compared with the mineral content of the original material. The greatest loss in basic substances was in the case of potassium, and the least in the case of sodium, the total loss of mineral salts being 44 per cent.

Due to the opinion that the basic element in the ash of foods is valuable in correcting acidity, comparison was made between the loss of basic and acid radicles in the cooked spinach. It is found that the loss in bases in the cooked spinach was 10.15 mg. per 100 gm.; of acids 4.13, but there is still in the cooked spinach considerable excess of bases. Separate determinations were made for the loss in iodine in cooking which were found to be 3.5 gamma (gamma — 0.001) for 100 gm. of fresh spinach. The loss is less than one-tenth of the original iodine content, the conclusion being that it is present in organic combination and not in the form of easily soluble salts.—A. Meiermeister, *Ztschr. f. Unter. der Lebensmittel,* Heft 2/3, Feb.–Mar., 1929, p. 235.

The Effect of Drying and of Sulphur Dioxide upon the Antiscorbutic Property of Fruits—Only one experiment in the literature on commercial dried fruit was found which, with the varying results reported on the canning and preparation of fruit, led to the work here reported. The fruit used was ripe peaches grown in California. The fruit was cut, pitted, ground, packed in small tin containers and kept in a freezing room at 17° F. Other portions were sun-dried (sulphured and unsulphured) and dehydrated (sulphured and unsulphured), sulphur dioxide being employed in the ratio of 1,840 to 1,875 parts per million. A scorbutic basal diet of rolled oats, skim milk powder, sodium chloride and cod liver oil was used. The animals (young guinea pigs) succumbed to scurvy on this diet in 25 to 35 days.

Five various modifications of fruit were given in separate test doses and all of the results are tabulated for the feeding periods, which varied from 32 to 90 days. All animals on unsulphured fruit, either sun-dried or dehydrated, succumbed early, in a manner similar to those on the basal diet alone. Animals on the sulphured fruit, both sun-dried and dehydrated, were practically free from scurvy for the 90-day period. The question was raised as to whether the protective action was due to decreased oxidation due to coagulation, or because of the reducing action of sulphur dioxide, or to greater stability of the vitamin in the more acid medium. Comment is made on the result of this investigation with the question as to the deleterious effect of sulphur dioxide on human health. Since arbitrary limits for sulphur dioxide in fruit have been placed by certain foreign countries and one or two states in this country it seems desirable to know at what sulphur dioxide content the protective action on vitamin C is effective. The antiscorbutic power of sulphured dried peaches is high, 1 gm. of the product being equivalent to 1.5 to 3 gm. of oranges or lemon juice, or fresh tomato, and to 3 times that quantity of banana, 6 times the amount of raw apple or pear or cooked potato. Similar experiments are being conducted on prunes and apricots and the effect of lye-dipping on vitamin C content is also being investigated.—Agnes Fay Morgan and Anna Field, *J. Biol. Chem.*, 82: 579 (June), 1929.

The South Carolina Food Research Commission—The South Carolina Food Research Commission was authorized in 1928 by the session of the South Carolina legislature to conduct studies on the iodine content of vegetables grown in that state. Tables are given showing the content of these vegetables compared with those grown in other states, which run from 98 p.p.b. in sweet potatoes to 754 in lettuce, in the dried vegetable. It has been suggested that the high iodine content of South Carolina vegetables is due to Chilean sodium nitrate. The authors point out that this nitrate contains very small amounts of iodine and the section of the state showing the highest goiter incidence and the lowest iodine in vegetables was the site of the largest use of Chilean nitrate. In a study of the effect of diet in goiter cases now under way, only 4 out of 27 cases so far investigated included vegetables in the diet.—William Weston and Roe E. Remington, *J. A. M. A.*, 92: 2161 (June 29), 1929.

The Respiration Factor in the Deterioration of Fresh Vegetables at Room Temperature—The rate of respiration was the index used to determine the degree of deterioration in fresh vegetables as handled for market, previous work having shown marked changes in green sweet corn and asparagus. A description is given of the respiration apparatus. The experimental material was fresh vegetables of edible maturity brought directly from the garden into the laboratory without wilting. The varieties used were beets, green onions, carrots, lettuce, green beans, pimentos, mangoes, okra, tomatoes and asparagus. The material collected was at a temperature of 30° C. and this was maintained as a working temperature. Determinations of respiration losses were made at intervals for a period of 30 hours. Curves are given showing the amount of CO_2 evolved per 100 gm. dry weight per hour. The total weight of carbon dioxide evolved was determined and by calculation the amount of glucose lost between the 2d and 26th hours. The vegetables, according to the amount of gas evolved for equal weights of dry matter, range in the following descending order: asparagus, lettuce, green bean, okra, green onion, carrot, tomato,

beet, green mango, red pimento. The corresponding amounts of glucose vary from 13.68 gm. per 100 gm. for asparagus to 1.29 gm. for pimentos.—Marjorie P. Benoy, *J. Agri. Res.*, 39: 75 (July 1), 1929.

Iodine Survey of Nebraska—Nebraska is not included in the goiter area of the United States, indicating appreciable amounts of iodine in the soil or water. To confirm this, samples of drinking water, soil and food materials were secured and analyzed. The soil samples indicated amounts from 0 to 15 p.p.b. and the water samples from 8.8 (at Lincoln) to 30 p.p.b. (at Peru). A table is given showing the iodine content of various foods grown in the state which varies in p.p.b. from 62 in cabbage to 220 in carrots. Corn, wheat and onions showed no iodine content. The water analysis did indicate that there is sufficient iodine except in the extreme northern part of the state where less than 5 p.p.b. of iodine are found. While the soil analysis indicates deficiency in iodine, it is believed that some of this was in soluble form and has been leached out by rain and surface water. Food materials are not regarded as low in iodine, comparing very favorably with figures reported for nongoitrous regions.—W. H. Adolph and F. J. Prochaska, *J. A. M. A.*, 92: 2149 (June 29), 1929.

Composition of Bone. VI. Effect of Massive Doses of Irradiated Ergosterol—This work records the analyses of a number of bones which were obtained from autopsied rats in experiments with massive doses of irradiated ergosterol. One group of rats was fed 2 gm. of cod liver oil to every 100 gm. of the ration, and another group was the control. The serum calcium of the control rats was 10.9 mg. per cent, that of the cod liver oil group was 13.9 mg. per cent, and that of the ergosterol group was 16.1 mg. per cent. The mean of all ratios of residual calcium of bone was found to be 2.00 compared to 1.99 for normal rat bones. Control ratios were 2.09 and 2.02, the ergosterol group 2.03, 2.00, and 2.04, and the cod liver oil group 1.91 and 1.93. Figures for the ratio in all of the bones of all of the groups closely approached the mean. —Benjamin Kramer, M. J. Shear, and Margaret R. McKenzie, *J. Biol. Chem.*, 82: 555 (June), 1929.

The Sanitary Significance of Leucocytes in Milk—It is difficult to understand the true significance of variable numbers of leucocytes and other types of cellular materials in milk without an understanding of the reason for their presence. The fat laden gland cells and gland cell nucleuses present in limited numbers in normal milk represent wastage from the active gland and have no sanitary significance. Leucocytes even in fairly large numbers, i.e., millions per c.c., may be present in milk that is normal so far as is evident from ordinary chemical or bacteriological examination. On the other hand, excessive numbers of leucocytes are usually associated with some abnormal condition, particularly mastitis. The usual form of mastitis is one caused by an infection with streptococci and these bacteria are usually evident among or in the leucocytes when the milk has come from a cow suffering from an inflamed udder. Pathogenic streptococci are sometimes difficult to distinguish microscopically from saprophytic streptococci. Other bacterial infections of the udder may also cause increased numbers of leucocytes to appear in milk.—Robert S. Breed, N. Y. State Agri. Exper. Sta. *Bull. No. 568* (Apr.), 1929.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

Maternal and Infant Mortality and Morbidity—Indications multiply that all over the world a concerted effort is being made to do something about that most outstanding problem of public health, the maternal and infant mortality rate. To do anything of importance about it, we must do two things: (1) learn more about the factors involved; and (2) get to the public the information we already possess.

There are many pitfalls, however, in getting such information to the public. It is too easy to become merely a propagandist and to give to the public as facts things which we wish were facts or hope are facts. There seems to be a great fear of acknowledging the limitations of our knowledge. And then there is the great delusion that all that is necessary to reduce the maternal mortality is to spend money.

It will be interesting to see what will be produced in the course of the campaigns referred to below, by two English speaking countries somewhat more given to conservative statement than we ourselves are. Both of the extracts to follow are from the *Child-Welfare News Summary*. The first is based on an article in *National Health*, London, June, 1929, p. 411:

> Under the auspices of the National Association for the Prevention of Infant Mortality a joint committee has come into existence for the purpose of enlightening the public on the subject of maternal mortality and morbidity in childbirth. The committee now includes representatives of 11 prominent organizations especially interested in the subject, and others have been invited to cooperate. All organizations of women, both national and local, whether technically interested or not, will be asked to assist. The committee plans to conduct a nation-wide campaign and has undertaken to prepare a panel of speakers for public meetings and supply them with up-to-date statistical material.

The second reference comes from our neighbor, Canada, whose problems are in many ways so similar to ours, and appeared in the *Canadian Child Welfare News*, Ottawa, May 15, 1929, p. 42:

> The Canadian Council on Child Welfare has announced that through the interest of the Canadian Life Insurance Officers' Association it will be enabled to undertake a 3-year intensive educational campaign in the field of maternal and infant welfare. The council has been carrying on considerable educational work in coöperation with the public health departments of the provinces in the distribution of simple prenatal letters and diet folders and other material on nutrition. The organization now plans to issue prenatal and postnatal literature, and malnutrition and diet folders, published in both English and French, which will be prepared and reviewed by competent authorities before release. A special feature of its work will be the preparation of health exhibit material, which will be available to other organizations, to conferences, and especially to women's conventions, fairs, and summer picnics in the smaller towns and cities and in the rural areas. The work will be directed by a committee of the child hygiene section of the council, which will include representative public health workers from different parts of the Dominion.

Baby Health Stations and Family Budgets—It is generally believed by young and inexperienced health officers that, given a large enough budget, they can forthwith banish disease from the world. It is sometimes believed by young social workers that bigger and busier clinics and more of them constitute the panacea for most of life's ills. Enlightenment—or disillusionment—often follows an open-minded study of the question. But open-minded studies

are not so common as they might be. However, the one reported by Margaret H. Lyman for the New York Tuberculosis and Health Association in *The Modern Hospital,* June, 1929, seems to be in that class.

The investigation in question studied the economic status of those making use of the 13 baby stations in the Bronx. Fifteen per cent of each station's registration during September and October, 1928, chosen at random, formed the basis of the study. Seven hundred and twenty-two families were visited in their homes and the usual social data obtained for the purpose of determining financial status.

The results showed that in 87 per cent of 501 families the father made his living at a trade or in a factory. Eighty-five per cent lived in 4 rooms or less. The families, in the majority of cases, consisted of 3 to 5 persons. More than one-fourth were considered to be living under unhealthful conditions.

Only 21 per cent of the families were considered to have incomes adequate to meet a standard of comfortable living. The investigators here show great self-restraint in that they do not commit themselves as to whether this 21 per cent should be expected to pay for service such as they went to the clinic for. They advise further study of the question.

It is greatly to be hoped that this further study may be forthcoming, and that someone will study with equal care those attending the many well child, dental, eye and other clinics in smaller places, often carried on at public expense.

Dental Hygiene in Massachusetts—The June issue of the *Commonhealth* (the quarterly bulletin of the Massachusetts Department of Public Health) contains an interesting statement on 10 years' progress in dental hygiene, and a more detailed report of the work carried on by that department during 1928. Dental work, especially on the part of municipalities, has grown rapidly of recent years in various states and this growth has not everywhere been a healthy one from a social point of view. In too many instances municipal or state departments of health have conducted dental clinics with little or no appreciation of the principle of family responsibility for medical care.

In 1919, states the article, Massachusetts inaugurated a dental advisory and informational service, in charge first of a dentist and later of a dental hygienist. At that time 43 communities in the state had a definite school dental program; at present the number is 223 (out of a possible 355). The number of school dentists has grown during this period from approximately 50 to 250. In 1919, there was only one dental hygienist in public health work in the state; at present there are 50 doing school work in the various communities.

Turning now to the report of the Consultant in Dental Hygiene for the year 1928, we get a more detailed picture of the way one state handles its dental hygiene problems. Work is carried on under a fixed policy which has the approval of representative state dental organizations. An advisory committee aids the consultant in matters of policy and regional consultants nominated by the president of the state dental society aid in local problems and situations. On the part of the local workers themselves, interest is evidenced by the formation early in the year of the Association of School Dental Workers, with a membership of 345.

A realization of the need of better training for school workers in dental hygiene resulted in a course for dental hygienists in school dental procedures being given at one of the state summer schools.

A general informational service, which

includes pamphlets, delineascope films, etc., is of course offered. It is interesting to note that the lecture service is being curtailed to give more time, it may be inferred, for work that is less of a shot in the dark.

One great danger of any dental program is that it may be confined to the group which makes use of the dental clinic. To obviate this, a campaign was started as part of the May Day-Child Health Day program which had as its object the interesting of every child and his parents in a clean mouth. A system of dental certificates was made use of, with rewards for child and schoolroom meeting the requirements laid down to insure clean mouths. This scheme had the merit of bringing the family dentist as well as the clinic into the picture.

On the whole, these two reports show what can be accomplished in the way of leadership when a state consultant in dental hygiene keeps his (or her, as in this case) feet on the ground, avoiding the insidious pitfalls of state clinics and other manifestations of so-called state medicine. Furthermore an advisory rather than a supervisory relationship seems best adapted to foster a strong local sense of responsibility.

Health of the Child in Industry—In spite of present-day interest in the health of the school child, most communities have strangely overlooked their responsibilities to that child who is partly in and partly outside the public school system; that is, to the child in industry who attends the continuation school. In an article reprinted from the *American Child*, Rowell discusses Preserving and Promoting the Health of Working Children, and starts off with the reasonable proposition: "Protection and promotion of health is just as desirable in continuation schools as in (the ordinary) public schools." Many children will or must go to work; how can we minimize or prevent entirely injury to their health?

The continuation school child is at a crucial period of his physical and mental life. He is growing rapidly and should be under strict supervision. It is often for his best interests that he be forbidden to go to work; at least, if he is allowed in industry he should be safeguarded against avoidable hazards.

Theoretically, it is pointed out, the health program of the continuation school should consist, as in the regular school, of health service, physical education and health education. As a matter of practice, however, there are difficulties in the way of this, due in part to the brief period each week that such children are in school.

Several interesting points are raised by Rowell with regard to present practices for handling health certification. Why is not use generally made of the cumulative health records supposedly available in the hands of the school authorities? Again, why should not the child be charged a small fee for the physical examination at the certificating office, the proceeds to be used to improve the health service?

A suggestion is made that in the case of certain adolescents a test may be made of their ability to do well under conditions in industry, by allowing them to work for a few weeks and then checking up on their reactions. Follow-up work by directing a child toward remedial measures may render him eligible to work.

The author, further, discusses the type of physical education desirable for those in the continuation school, based on the type of work the individual is engaged in. The requirements of the clerical worker are not necessarily those of the shop worker. Health instruction is dealt with at some length. The difficulties here are of various kinds, such as the wide spread of mentality of the pupils and the usual lack of health

background of the continuation school teacher. Methods of approach to different classes of pupils are discussed.

Emphasis is laid on the necessity for: (1) a health education specialist in all continuation schools; (2) more research; (3) a well planned program based considerably on local needs.—Hugh Grant Rowell, M.D., Preserving and Promoting the Health of Working Children, *Pub. No. 352*, National Child Labor Committee.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

THE INTERNATIONAL COUNCIL OF NURSES' CONGRESS IN MONTREAL

All attendance records for congresses of the International Council of Nurses were beaten when 8,000 nurses from all quarters of the globe met in Montreal July 8–13.

The countries whose national nursing associations are affiliated with the International Council of Nurses are Great Britain, United States, Germany, Canada, Denmark, Finland, Holland, India, New Zealand, Belgium, China, Italy, Norway, South Africa, Bulgaria, Cuba, France, Irish Free State, and Poland. The Nursing Associations of Brazil, Greece, Jugo-Slavia, the Philippines, and Sweden became affiliated with the I. C. N. in a very touching ceremony at this meeting. Nurse delegates were sent from all these countries to Montreal; in some cases their expenses were paid by their governments.

Other countries sending nurse representatives to the meeting were Czechoslovakia, Esthonia, Iceland, Japan, Korea, Latvia, Switzerland, Turkey, Hungary, Palestine, Spain, Syria and Uruguay.

The three countries affiliated with the International Council of Nurses having the largest memberships in their national nursing associations are the United States with 75,000 members, Great Britain with 33,845 members and Canada with 10,216 members.

One might wonder what so many nurses, from so many countries with languages, customs, races and traditions so different, could have in common in a professional way. But for one who had never before attended an I. C. N. convention the similarity of aims and ideals of the forward looking nurses in all the countries was striking. All were bending their efforts to raise the educational standards and improve the social status of the nursing profession. And Nina Gage, R.N., of New York, President of the I. C. N., in her address on the opening night, spoke the key words of all the proceedings at the Congress when she said: "Through all our problems runs the scarlet thread of our ultimate object, better care of patients, whether in home or hospital, ill or prevented from becoming ill."

Mlle. L. Chaptal, Directress of the "Rue Vercingetorix" School of Nursing in Paris and President of the National Association of Trained Nurses of France, is the new President of the International Council of Nurses.

The next Congress will be held in Brussels and Paris in 1933.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

The Place of Health Exhibits at County Fairs—People go to county fairs more for the purpose of seeing things than to have things done. They see prize products from over the county on exhibit; conceive new ideas about different degrees of perfection; and go home determined to attain a new perfection in the various phases of farm life.

It seems logical then that a health exhibit at the fair is the thing most needed to make people go home and do the things that will promote personal and community health. Experience in Texas has shown that health conferences cannot be successfully conducted at county fairs.

Public health nurses in Texas are asked to arrange exhibits at their fairs and have pictures taken of these exhibits to send to the Texas State Board of Health, with a description of the apparent effectiveness of the exhibits. These will be discussed at the next staff conference of public health nurses and all will gain new ideas and suggestions for next year's fair work.—H. W. Barnett, News Items from the Texas Field of Public Health Nursing, *The Gleaner,* June, 1929.

The Public Health Nurse and the County Doctors—If a nurse must choose between having a large number of children receive toxin-antitoxin administered by state workers at cost, and a smaller number receive it administered by the family physician at an increased cost, she should choose the second alternative because in the long run it is better to keep the confidence and favor of the doctors which she needs to carry on her whole health program in the community.

If the public health nurse advises patients to attend the free tuberculosis, dental or baby clinics put on by the state, without due regard to the rights of the family physician, friction will ensue. So it is better that patients should be referred to the clinics by the family physician, and any treatment advised should come from him.

A public health nurse should be wary about accepting a patient's word that his financial condition will not permit him to pay for medical treatment, unless she is otherwise very sure of it. In case of doubt it is always well to consult his physician if he has one. There are families, however, who have not the means for necessary medical attention, and here again the family physician, if there is one, should be given the chance to treat the family free, or at a nominal charge if he cares to, or suggest sending the patient somewhere else.—Nancy W. Rand, R.N., The Public Health Nurse and the County Doctors, *The Echo*—Virginia State Health Dept., IV: 150 (June), 1929.

If there is no family physician or if he is not available, every effort should surely be made to conserve the best interests of the patient.

Health Day at a Teachers' Institute—In Indiana the superintendent of schools in each county arranges a 3-day institute for all teachers in the county schools. These institutes are generally held the week before school begins in the fall. The public health nurse usually has to be content with from 15 minutes to an hour of the program time to explain her health plans for the coming year to the teachers, and she always has an exhibit of health material at the meeting.

This year the school nurse in Randolph County prevailed upon the County Superintendent of Schools to allow her to have one whole day of the institute for a health program. She has arranged to give a demonstration of a teacher's morning inspection of pupils, and following this there will be a discussion of the teacher's part in the health program. Then she has ar-

ranged to have a man prominent in this particular field speak for an hour on the subject "The Subnormal Child." In the afternoon there will be a lecture on Health Education by a teacher from a neighboring state who has done outstanding work in this line, and for the last thing on the program the State Health Commissioner will address the teachers on "The Modern Control of Communicable Disease." There will be plenty of time for questions and discussions after each address.

A novel feature of the meeting will be a session for school janitors and the State Health Commissioner will address them on School Sanitation. This county has eighteen consolidated schools and no one room rural schools, so that every school has a janitor, and each janitor has promised to come to the meeting.

School Nursing as a Career—The old idea of school nursing emphasized the negative aspects of the health program, and consisted mainly of detecting cases of contagion and physical defects and making home visits to try to persuade the parents to secure corrections.

The modern school health problem is a positive thing—it tries to develop fine children and reaches every child in school. Now, however, the school nurse is only one participant in a big school health program, and the effectiveness of her contribution depends on the willing coöperation she receives from the teaching staff in the school and her coworkers in the community.

The school nurse acts as the representative of the commissioner of health in her school contacts, and in matters that concern health should be the consultant and adviser of the superintendent of schools.

The first personal qualification a school nurse should have is good health, both mental and physical, and this should mean that she has a good store of energy and is good natured. She must also have a genuine love of people.

On the professional side she should be a high school graduate, and have her nurse's training in a hospital nursing school of high standing. On top of this, a generalized training in public health nursing, as postgraduate work, is necessary. In her public health course she should have plenty of opportunity to study normal children to enable her to handle better the usual childhood problems.

Skill in newspaper and general publicity methods will be of great value to the nurse in interpreting the needs of child health in the community. Teacher training and experience are extremely valuable to her as she is always a teacher herself and this training helps her to appreciate the teacher's problems in the classroom.

There is great need of school nurses with good educational background to do research work in the correlating of regular school subjects with the school health program.

The following are some problems in school health work where a school nurse's research work would make valuable contributions to both modern educational and preventive health methods:

1. Causes of absences of school children
2. How best to control contagious disease
3. Effect of extra nourishment on underweight children
4. Progress of individual children who present peculiar difficulties
5. Comparison of health of children who live in coöperative and incoöperative homes

A school nurse who sees her opportunities can be an unlimited influence for good in a community and especially in the lives of its boys and girls.—Elma Rood, School Nursing as a Career, *J. Nat. Ed. Assn.*, 18, 5: 147 (May), 1929.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Meet the Editor at Minneapolis—What was best in your publicity last year? In what did you fail or have but moderate success? What experiments have you made? What tests? What new methods, or old methods tried in a new way? What questions do you want answered?

The editor of this department and associates in the Public Health Education Section will be at Education-Publicity Headquarters most of the time between section meetings. Join the group—to give to others, to glean for yourself. Consultations with specialists will be arranged for all who wish them.

What Will You Send to Minneapolis?—Will you send leaflets, folders, booklets, posters? Educational or money-raising letters? Posters, placards, car cards? Copies of radio talks? Topics for health speakers? Slogans or titles? News stories or news photographs? Lists of publications available? Lists of pictures or exhibits? Campaign scrap books?

What have you? A single piece of printed matter, or a varied collection of publicity material? *Please write quickly for instructions,* addressing the chairman of Headquarters and Exhibit Committee, Evart G. Routzahn, 130 East 22d Street, New York, N. Y.

Matter for free distribution should be addressed:

Free Distribution
Education-Publicity Headquarters
Minneapolis Auditorium
Minneapolis, Minn.

But please write in advance if you expect to send anything for the classified display at headquarters.

If They Do or If They Don't—In any case the A. P. H. A. meeting in Minneapolis is an opportunity of significance.

If staff workers know all about their jobs in publicity or health education, Minneapolis will be an opportunity to share with others.

If staff members lack knowledge or experience, a few days at Minneapolis will be the best possible investment of department or association funds.

Those who handle motion pictures or send out exhibits, those who get up printed matter or distribute it, those who deal with newspapers, and those who work with the schools—all will find much at Minneapolis that they can use in "their business."

What Shall Be Told?—How much should the public be told about vitamins? What is it reasonable to say about brushing the teeth? What exaggerations and mis-information on health topics are found in current advertising and health publicity?

You are invited to submit material, either your own—for approval, of course—or some from another source of which you disapprove, to the clinic on "What to Tell." Much attention has been given in past meetings to ways and means of making health information interesting, clear and convincing. At one meeting of the Public Health Education Section in Minneapolis the intention is to go behind the form of presentation and discuss the subject

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

matter—what facts need greater emphasis, what statements, although essentially true, are misleading; in other words, what the public should and should not be told in 1929. Please send good and bad examples to the editor of this department as soon as possible.

Study Exhibits in Action—The popular health exhibition, which will be held in the main auditorium as a feature of the A. P. H. A. meeting at Minneapolis, is intended to appeal chiefly to the lay public. The exhibition will be widely advertised in and about Minneapolis and a large attendance is expected of persons to whom popular health education is addressed.

Here is an unusual opportunity for those engaged in health education to study exhibits in use, noting the response of visitors to different methods of display and to different subject matter. The exhibits are being prepared by public and private health agencies of Minnesota under the direction of Richard O. Beard, M.D.

For the Head-line Reader—Statistics do not always lend themselves to picturesque comparisons, or to other forms of simplification which help to make the average reader grasp their significance. Perhaps the following bewildering sequence of percentages must stand as it is:

> Practically 62 per cent of all surgical cases remained in the hospital less than 11 days while only about 43 per cent of the medical cases stayed less than 11 days. Most of the obstetrical cases come within the 11–19 day period, while the highest percentage of cases requiring more than 20 days is to be found in medical cases where nearly 42 per cent of them require more than 20 days as compared with 17 per cent of surgical cases and 3 per cent obstetrical cases.

Blue pencil about half the words in those two sentences, and the statistical facts will stand out more clearly. Why not try this form: "Six in 10 surgical cases left the hospital in less than 11 days"?

In contrast to the above is the opening sentence of a news story on a similar report:

> The average New Yorker, entering a local hospital at 9 o'clock next Monday morning as a sick man, will be discharged at 6:27 p.m. on the second following Wednesday, according to a survey just completed by officials of the United Hospital Fund. . . .

The Illinois Department of Health (press release dated July 14, 1929) makes graphic the cost of smallpox:

> Spending together more than 300 years in quarantine is what 5,400 people have already done this year in Illinois because of smallpox. The State Department of Health has spent about $67,000 for the same reason. Nobody wants the disease and nobody wants to be vaccinated. Hundreds of years in quarantine and thousands of dollars in useless expense is the result.
>
> So far about 2,700 cases of smallpox have been reported in Illinois this year. For each case at least two people have been under quarantine for no less than 21 days. Travel and salary of state health authorities for all time spent in combatting smallpox amounts to an average of about $25.00 per case. Three or four thousand cases of smallpox per year, therefore, costs a sizeable sum and causes no insignificant number of people to spend a considerable amount of time in almost solitary confinement.

A Governor Looks at Public Health—Said Governor Franklin D. Roosevelt at the recent Annual Conference of Health Officers and Public Health Nurses of New York:

> . . . In the final analysis public health must depend on the locality. Today in county after county the average amount spent for health improvement is under 50 cents per capita, while those same counties spend $4, $5, and $6 for improvement of highways. This is just an example. I do not want the highway work to stop, but the proportion is out of line if we figure it on the population and the future generation. . . .
>
> Some of the widely scattered rural counties are doing better work than those containing large civic communities. It comes down to the interest aroused among the people themselves. . . . If we can obtain from the indi-

viduals of the electorate the right to see that the health of communities is kept up to the best modern standards we will be doing a fine piece of work.

The Thirteenth National Baby Week—In July, 1929, England celebrated the thirteenth consecutive annual National Baby Week.

In the development of its activities the Council found that in addition to the one week's intensive campaign during the first week in July, local Baby Weeks became very influential and important. These local campaigns were and still are being held at various periods throughout the year—at times found to be the most favourable to the area concerned in the campaign. The National Baby Week Council reports yearly an increasing number of these local baby weeks.

DATES AHEAD

Nov. 11–17—"American Education Week." Address: National Education Association, Washington, D. C.

REGRETTABLE BUT TRUE

That one city department of health devoted a dozen pages to "Causes of Death" and other statistical matter—followed by three pages of interesting text. Why not reverse the arrangement?

WORDS

Few people have a "physician." Most people "go to a doctor." Is there a weak spot in the health examination campaigning in the repeated urging to see "*your* physician"?

"Human and animal *dejecta*"; "*foci* of infection"; "water courses *traversing* or draining inhibited regions"; "contaminated by *human feces*."—A state department press release.

"The variations in temperature, both seasonal and *diurnal*." In a radio talk.

An Explanation with Regrets—A seven weeks' absence from the office—the longest period away from business in ten years or more—is responsible for the absence of this department from one issue of the JOURNAL. The editor deeply regrets his inability to prepare copy in advance.

The department will appear as usual in subsequent issues.

BOOKS AND REPORTS

A Lost Commander. Florence Nightingale—*By Mary Raymond Shipman Andrews. New York: Doubleday, Doran,* 1929. 299 pp. Price, $3.00.

In the pages of the glamorous story of public health, Florence Nightingale deserves an exalted place. As the founder of modern nursing, her dramatic career has been the inspiration for a legion of women whose lives have been consecrated to healing the sick or carrying to the people the gospel of good health. The narrative has been told many times and it is one with which every sanitarian should be familiar.

This particular retelling of what ought to be a well-known tale is the work of a trained novelist turned biographer. The book is competently, at times beautifully, written, but it also bears some of the marks of journalism. The first chapter, for example, rather effusively, if effectively, describes a romantic incident which has never been authenticated, as the author admits. The second chapter is inclined to be equally imaginative, but after that the book swings into facts, such as the glorious story of Scutari, where "the Lady with the Lamp" rendered her first conspicuous service.

Notable as she was in the Victorian era, Florence Nightingale was no plaster saint, though certainly not the disagreeable martinet she has been painted in the bilious biography of the cynical Strachey. There seems, however, a tendency toward glorification in this book by Mrs. Andrews. Nor was Miss Nightingale a "lost commander," but a truly great leader whose influence on English progress in certain fields, such as sanitation, hospitals, nursing, and even medicine, was tremendous—and lasting.

The book is a pleasure to read, not only for its excellent content, but because of the attractiveness with which it has been printed.

"There were many facets to that diamond called Florence Nightingale," says the author. There were indeed; but the really brilliant narrative of her life remains to be told. Capable and interesting as is this one, a better will be written some day, not by invitation from a metropolitan publishing house, nor on the whim of an established writer, but by some obscure nurse or sanitarian who has lived the same romance that was the life of the Lady with the Lamp. JAMES A. TOBEY

Ergebnisse der Sozialen Hygiene und Gesundheitsfürsorge—*Edited by Prof. Dr. A. Grotjahn, Professor of Social Hygiene, Prof. Dr. L. Langstein, Professor of Children's Diseases, and Prof. Dr. F. Rott, Docent in Social Hygiene, the University of Berlin. Leipzig: G. Thieme,* 1929. Vol. 1, viii + 440 pp., 31 figs. Price, M. 30, bound, M. 33.

The aim of this new journal in the field of social hygiene is to present trustworthy and critical summaries by competent specialists of the progress made in the various subdivisions of this rapidly advancing science, and in its applications. It aims to summarize the results of fundamental investigations, of the more specialized aspects of social hygiene, and of the borderlands of this subject. It aims to meet the needs of investigators and of physicians engaged in social insurance, of those in the clinical and laboratory fields, and of those

interested in the organization and administration of measures of social hygiene.

It aims to represent the fields of eugenics and reproduction, constitutional and anthropometric investigations, hygiene and sanitation, education in hygiene, vital statistics and population changes, control of epidemics and sanitary legislation, social insurance and health promotion, social hygiene for mothers, children, youths, and the aged, care of cripples, the tuberculous, and those with venereal disease, social psychiatry and psychopathic enterprises, prevention of alcoholism and narcotism, social statistics, hospital facilities and hospitalization, the relations of health measures to the growth of public and private interest in the promotion of social hygiene.

The first volume has 12 special summaries by specialists, dealing with such subjects as the decline in infant mortality, contraception, sterility and mortality in the districts of Berlin, with reference to their social composition, school dental service as a community health measure, and the theoretical program of social hygiene. American readers will be interested in Dr. Béla Schick's discussion of protective immunization against diphtheria in the United States.

This new addition to the "Ergebnisse" of the German scientific press fills a distinct need in a growing field, especially that created by the growth of social efforts along the line of preventive medicine. C. A. KOFOID

Foods of the Foreign-Born in Relation to Health—*By Bertha M. Wood. Boston: Barrows. (2d ed.)* 1929. 110 pp. Price, $1.25.

Diets employed in hospitals and institutions and those recommended at clinics and dispensaries serving large numbers of foreign born persons ought to be adapted, within the limits of sound nutrition, to the dietary habits of the different nationalities served. In order to do this satisfactorily, it is, of course, essential for doctors and dietitians, nurses and social workers, to know something about the food customs of the various racial groups.

In this little book the author presents much useful information about the foods of Mexicans, Portuguese, Italians, Hungarians, Poles and other Slavic peoples, Near East peoples, and Jews. Suggestions are also made regarding therapeutic diets for special purposes. In these days of frenzied prohibition it is interesting to read that the daily diet of the Hungarians in their own country contains whisky and that these combinations do not change much here. Probably not.

A new appendix in the second edition, which has been published about 7 years after the first, gives the proportions of protein, fat, and carbohydrate in the various food combinations mentioned throughout the text. If it also gave the minerals and vitamin content, it would possess much greater nutritional significance.

The book is fairly well printed and has an index of recipes. There is a foreword by M. M. Davis, written in 1921. This book ought to be useful for its purpose. JAMES A. TOBEY

Communicable Diseases for Nurses—*By Albert G. Bower, M.D., and Edith B. Pilant, R.N. Philadelphia: Saunders,* 1929. 327 pp. Price, $3.00.

This book seems to give all the information in regard to communicable diseases found in the most up-to-date books on the subject designed for public health workers, with the additional distinction of laying most emphasis on practical nursing technic and care in the treatment of these diseases.

The authors state that acquired active immunity from diphtheria is still

in an experimental stage, when 8 or 10 cities in the United States have reduced their death rate from diphtheria to almost zero by the widespread use of toxin-antitoxin. The authors also state that large doses of toxin-antitoxin may be given and repeated as often as necessary to obtain results, when it has been thought that the best method is to give the one large maximum dose in the first place and obviate the necessity of repeated doses.

This is a valuable book for not only nurses but housewives, and even physicians, to possess. It is easy reading, has a good glossary and good illustrations, some of them in colors.

EVA F. MACDOUGALL

The Struggle for Health—*By Richard H. Hoffman, M.D. New York: Liveright,* 1929. 341 pp. Price, $3.50.

The most conspicuous struggle here is the laborious endeavor of the author to present the entire history of medicine for popular consumption. The result is a somewhat ponderous, closely printed volume which depicts, with many collateral remarks obviously intended to be clever, the development of medicine from the days of Pithecanthropus Erectus to Freud.

Despite a dull beginning, much of the book is entertaining, especially when the author drifts into anecdote. In the apparent attempt to include every detail, however, much of the material becomes a mere catalog of facts, an array which gets bewildering rather than fascinating, as the subject warrants.

The book displays a rather poor sense of relative values in the story of health. Thus, Pasteur, the founder of modern preventive medicine, who deserves at least a whole chapter in any such work, is accorded only about 4 pages, just half the space devoted to Aureolus Theophrastus Bombast von Hohenheim, commonly called Paracelsus, who was as much a charlatan as anything else. Similarly, Lord Lister and Florence Nightingale are honored here with only a page each. In the chapter on mental hygiene there is no mention at all of Dorothea Dix or Beers, and only a sentence or two on Pinel.

This lack of balance is further accentuated by a sudden transition from historical narrative to a discourse on the internal secretions, forming Chapter XV, which is, moreover, one of the most interesting parts of the book. In a chapter on X-ray there are several pages on nutrition, in which only 3 of the 6 or more known vitamins are described, though the book was obviously written quite recently.

This book is well printed with respect to freedom from typographical errors, but the print is several points too small. By what process of logic does a publisher issue a book on a health topic with print that might cause eye strain in many sensitive readers? Such a poor conception of hygiene deserves condemnation.

The sanitarian directly interested in medical history may find this book of value, and the layman may derive some entertainment from it, but there are many standard works not yet improved upon which are available to either group of readers. This one is not "the" struggle for health, but a struggle.

JAMES A. TOBEY

The Physical Welfare of the School Child—*By Charles H. Keene, M.D. Boston: Houghton, Mifflin,* 1929. 505 pp. Price, $2.40.

Books of substance and "easy reading" qualities are always sure of readers, especially in the field of public health. This new book by Keene is full of valuable material, simply written, and has a good index.

The plan of the book is to set forth

"the threefold duty of the school" (protection, correction and prevention) through a discussion of the "seven parts of a unified program": sanitation of the school plant; physical education; health supervision; hygienic arrangement of the school program; health of teachers; training of teachers; health training and instruction. These subdivisions are not treated exhaustively, of course, but in sufficient detail for the purpose. References are constantly given to sources of more extensive treatment of the given topic.

So much for a few of the obvious strong points of the book, of which there are many. It is a book written by a man of wide experience and strong convictions—both experience and convictions are very evident. The reviewer has the uneasy feeling that in spots the book may convey to the inexperienced student in normal school or college a sense of finality concerning certain highly controversial subjects which transcend the public health field and get into that of economics, of government or what not. Some will wonder whether it is entirely in accord with sound public policy to turn our public schools into surgical dispensaries where the child has his teeth filled, pulled, straightened; his tonsils snatched from him; his eyes treated—all at public expense.

Somewhat disproportionate space is given to the question of who should administer the health supervision program in the schools, the stand being taken that unquestionably it belongs almost solely to the educational authorities. As a matter of fact, it is usually carried out equally badly by school or health department. Both, on the other hand, would seem to have responsibilities toward the school child which cannot be dodged.

What has been said above concerning certain controversial aspects of the book merely indicates that it is stimulating, and heaven is always to be praised for a stimulating book. The reviewer heartily recommends it to school physicians, nurses, public health workers in general, as well as to discriminating students in college or normal school.

MERRILL E. CHAMPION

Morphologic Variation and the Rate of Growth of Bacteria—*By Arthur T. Henrici, University of Minnesota. Springfield, Ill.: Charles C. Thomas.* 194 pp. Price, $3.00.

As a source of comfort this contribution of Henrici's should be welcome to both camps of the forces battling over the subject of bacterial variation. As a result of tedious but careful research aided by clear and accurate analysis this author has furnished a new basis for consideration of the problems related to the fixity of bacterial species and the study of "life cycles." The work is primarily concerned with studies of the early stages of bacterial growth in which it is shown changes fully as significant as those occurring in old cultures are invariably found. Enumeration, measurement, and study of morphology of bacterial cells has been carried on throughout the entire period of bacterial growth, and by judicious use of statistical methods the conclusion has been reached that "morphologic variations of bacteria are an expression of the variations in growth rate."

It is not within the province of the reviewer to evaluate the experiments performed, nor to comment upon the significance of the conclusions reached. It is sufficient to state that this contribution warrants very careful study by all who are interested in the subject of bacterial variation.

Certain features of the monograph deserve special mention however. The publications of such workers as Lohnis, Enderlein, Almquist, Mellon and others relating to life cycles in bacteria are so confusing to many readers, partly be-

cause of the multiplicity of terms, as to render comparison and evaluation difficult if not impossible. Henrici in his opening chapter reviews this literature in a clear and concise manner, and leaves one with a very clear understanding of the present status of the problem. The remainder of the book is concerned with a report of the experiments performed and an analysis of the results obtained. One is impressed with the extent of the researches involved, with the ingenuity of the methods used, and with the excellence of the analyses given. The writer can scarcely be accused of being dogmatic although his conclusions support the monomorphistic view. He does not deny the existence of life cycles, but logically points out the conditions which must be met before such sexual development of bacteria can be accepted as proved.

The book is well written, well indexed and typographically pleasing.

N. W. LARKUM

A Manual of Helminthology—*By H. A. Baylis. New York: William Wood,* 1929. 303 pp., 200 figs. Price, $10.00.

This is a very welcome and valuable manual of the parasitic trematodes, cestodes, nematodes and related round worms known to occur in man and in the domesticated animals of temperate regions and the tropics. It will be an exceedingly useful work since there has been much written in these fields in recent years and the literature of the subject is widely scattered in many journals difficult of access except in the few great libraries of the world. The author's access to the library and the collections of the British Museum has given him exceptional facilities. His work is a synoptic treatment, with brief but well set-up accounts of the genuses and species of these parasitic worms of medical and veterinary interest. There are many new illustrations and good host parasite lists. It is of interest to note in these lists that man has to his credit as parasites 30 flukes or trematodes, 28 tape worms or cestodes, 58 nematodes or round worms and 3 Acanthocephala or thorny-headed worms, a larger number than any one of his domesticated animals has acquired. Possibly this is an index of medical as against veterinary interests in parasitology rather than an indication of differential sanitation or species susceptibility to infection.

C. A. KOFOID

Everyday Doings in Healthville—*By Emma Serl. New York: Silver, Burdett,* 1929. 128 pp. Price, $.68.

The fundamental health activities which should be carried out in the daily routine life of every child are emphasized in story form. The animal characters, Bettie and Bobbie Squirrel, have been personified by the author as inhabitants of Healthville in a manner which will interest the primary grade child.

This supplementary reader has been illustrated by Harry E. Wood, whose illustrations of children's books have created much favorable comment lately.

ANNA B. TOWSE

Guide for a Health Program—*By Jessie I. Lummis and Willidell Schawe. Yonkers, N. Y.: World Book Co.,* 1929. 196 pp. Price, $1.24.

The authors, who have recently contributed a series of health readers to the meager supply of health education material, have prepared this teacher's manual for the first, second and third grades. Teachers of health education will welcome this additional aid of detailed activities for a health education program and the reasons thereof. The manual is profusely illustrated and carries a section listing the materials that can be obtained for use in the schoolroom.

ANNA B. TOWSE

Psychiatry in Industry—*By V. V. Anderson, M.D., M.A., Director of Medical Research, the R. H. Macy & Co., Inc. New York: Harper,* 1929. 364 pp. Price, $4.00.

A book in this field from the psychiatrist's standpoint which also deals extensively with industrial psychology is welcomed. Four years of personnel problems in one of the largest mercantile establishments of the country where the employment office handles 15,000 cases a year, with the aid also of psychiatric social workers, has afforded a considerable experience. The book contains many summaries, extensive case discussions, the relative values of various mental tests along with their descriptions, the application of psychiatry to administrative methods, and a pleasing touch of somewhat philosophical observations. Psychological tests are found to have but a limited part in adequate job placement while a thorough medical and psychiatric study comes nearer solving the problem.

Radical changes in personnel and duties in different departments of the business were brought about with resulting great improvements through the methods used.

The chapter on health is devoted to chronic hospital users, compensation and sick leave cases, situation-reaction cases, fatigue problems, and frank cases of nervous and mental disturbances. Practically nothing is mentioned of associated physical findings and medical treatment so that one is a little skeptical whether, for instance, the 35-year old female described on pages 160–164 who had "nothing of importance except 20 pounds underweight" and complained of a group of symptoms suggestive of a toxicosis, possibly endocrinal, was entirely a psychoneurotic. Where the usual hospital experience reports about 25 per cent of patients suffering from neuroses, the author is convinced there is a much larger percentage in the rank and file. About 9 per cent of those examined physically for employment were rejected because of physical disorders.

Rather striking results of the psychiatric handling of the firm's automobile drivers are described. Among 450 of these there occurred a monthly reduction of 50–82 per cent in accidents, and a decrease of 92 per cent in labor turnover within one year, apparently consequent upon the tests. However, the reviewer feels this field is still too new to accept too great positivity of statement as to cause and effect.

There is an index, but no bibliography, although a half-dozen references are mentioned as of value for employment reviewers on page 193. The type is large, the reading easy and of excellent literary style. An appendix shows the inquiry forms and sample tests used. The book should appeal to professional and business men and to students as well as to all interested in personnel problems. EMERY R. HAYHURST

An Hour on Health—*By Morris Fishbein, M.D. Philadelphia: Lippincott,* 1929. 158 pp. Price, $1.00.

This little book belongs to the "One Hour Series," and one may well spend more than that time on its perusal. Beginning with the question of the length of life, which interests everyone, even those who profess a great desire to depart from this wicked world and enter the realms of the blessed, it covers in succession a number of subjects relating to health.

Perhaps the outstanding feature of the book is the attack on fads which are treated both with humor and philosophy. The faddists and the fakers understand human nature better than the average of their fellowmen. The author emphasizes this point in saying that is doubtful if any religious cult could achieve complete success unless it laid stress either on food or sex. We

agree with him that practically all faddists take themselves too seriously, and develop their special twists at the expense of the rest of their nature. Certainly the average faddist of any kind is an intolerable bore.

The book is easy reading, generally sound, and within its scope can be recommended. M. P. RAVENEL

Aerztliche Sachverständigen-Tätigkeit auf dem Gebiete der Hygiene—*Von Geh. Med.-Rat. Dr. O. Solbrig. Berlin: Urban & Schwarzenberg,* 1929. xii + 514 pp., 47 figs. Price, M. 33 (Bound, M. 39).

This is Volume 10, part 2, of Dr. Dittrich's series of informational professional handbooks and deals with hygiene, largely from the standpoint of sanitation and sanitary engineering, with minor attention to personal hygiene. The first section deals with soil in relation to air, water, and bacteria; water, its sources, physical and chemical properties, and its biological and bacteriological examination and control; mineral waters and ice. The second is concerned with nutrition, the sources of food, animal and vegetable, and of stimulants, clothing, and dangers to health from dirt, poisons, and dyes; and with dwellings, with special reference to factors of material, construction and arrangement as these affect health, and sanitary precautions in heating, lighting and ventilation.

The third chapter is concerned with municipal hygiene, city planning of residential districts and public institutions, transportation by ship and rail; water supply, sources, purification, removal of iron and manganese, softening, and organization and equipment of a scientific water control system; sewage disposal by various mechanical and biological methods, intermittent filtration, activated sludge, etc.; domestic systems, disinfection and methods of investigation; and a final section on mass feeding of children, soldiers, prisoners, the care of people's kitchens, consumers' coöperatives, municipal markets, abattoirs, supervision of the traffic in foods and inspection of imports.

The closing chapter deals with school and industrial hygiene. The former is treated from the standpoint, first of the buildings, their construction and care, and second from that of the personal hygiene of the pupil and the function of the school physician and dentist.

Industrial hygiene is discussed in its generalities, such as dust, gases, hours of labor, women and children in industry. There follows a detailed discussion of the various subdivisions of trades and industries which have reached so wide a diversification in modern industrial Germany. The work is replete with information, very well organized, significantly illustrated, and comprehensive in scope. It gives an excellent picture of the best German practice in hygienic matters where the sanitary engineer and public health physician are concerned.

C. A. KOFOID

Laboratory Directions in College Zoology—*By Henry Lane Bruner. New York: Macmillan,* 1928. 163 pp. Price, $1.40.

This is the laboratory outline accompanying the elementary course in zoology at Butler University. It follows the usual outline of a progressive survey of animal types from amebas—in this case not to man, but to the pigeon—with an introductory exercise on protoplasmic circulation in *Elodea.*

The course is planned for a year's work with two laboratory sections weekly. The invertebrates studied include the tape worm and *Ascaris.* Considerable attention is given to the physiological relations of the organs studied.

C. A. KOFOID

Psychiatry in Industry—*By V. V. Anderson, M.D., M.A., Director of Medical Research, the R. H. Macy & Co., Inc. New York: Harper,* 1929. 364 pp. Price, $4.00.

A book in this field from the psychiatrist's standpoint which also deals extensively with industrial psychology is welcomed. Four years of personnel problems in one of the largest mercantile establishments of the country where the employment office handles 15,000 cases a year, with the aid also of psychiatric social workers, has afforded a considerable experience. The book contains many summaries, extensive case discussions, the relative values of various mental tests along with their descriptions, the application of psychiatry to administrative methods, and a pleasing touch of somewhat philosophical observations. Psychological tests are found to have but a limited part in adequate job placement while a thorough medical and psychiatric study comes nearer solving the problem.

Radical changes in personnel and duties in different departments of the business were brought about with resulting great improvements through the methods used.

The chapter on health is devoted to chronic hospital users, compensation and sick leave cases, situation-reaction cases, fatigue problems, and frank cases of nervous and mental disturbances. Practically nothing is mentioned of associated physical findings and medical treatment so that one is a little skeptical whether, for instance, the 35-year old female described on pages 160–164 who had "nothing of importance except 20 pounds underweight" and complained of a group of symptoms suggestive of a toxicosis, possibly endocrinal, was entirely a psychoneurotic. Where the usual hospital experience reports about 25 per cent of patients suffering from neuroses, the author is convinced there is a much larger percentage in the rank and file. About 9 per cent of those examined physically for employment were rejected because of physical disorders.

Rather striking results of the psychiatric handling of the firm's automobile drivers are described. HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

New Jersey—This 51st annual report reviews at the outset the morbidity and mortality data for the year 1927, and shows a death rate of 11.4, the lowest ever recorded for this state. In 66 communities, representatives of the State Health Department assisted local health and educational bodies by introducing the subject of diphtheria immunization to the public, exhibiting motion pictures, supplying literature and record forms, and conducting clinics. It is estimated that throughout the state 173,000 children have been immunized in public clinics, not including those who were immunized by physicians in their private practice. This is one-fifth of the susceptible children in the state.

An epidemiological study of an outbreak of paratyphoid fever proved it to be transmitted through unpasteurized milk. Further spread of the disease was promptly prevented when department representatives stopped the sale of raw milk. A typhoid fever outbreak was also traced to a raw milk supply. In last year's report, reference was made to an extensive outbreak of scarlet fever (more than 200 cases). As usual, a missed human case of the disease was considered responsible. An unusual feature was that a cow in a certain dairy herd developed inflammation of the udder which yielded hemolytic streptococci.

Studies of the organism isolated from the milk showed it to be indistinguishable from the streptococcus of scarlet fever. "The udder infection appears to be the logical explanation of the massive infection of the milk, and stresses anew the importance of pasteurization."

The infant mortality rate of the state continues to decline, and 18 communities have adopted the department's continuous child hygiene program. In an attempt to determine upon a practical maternity hygiene plan suitable for municipal health department practice, the Bureau of Child Hygiene has set up an experimental prenatal center where a 5-year program will be carried out. The report abounds in good statistical tables and charts with appropriate descriptive text.

Rockford, Ill.—Rockford reports for 1928 a population of 83,700, a death rate of 9.18, a birth rate of 15.7, and an infant mortality rate (all rates corrected for residence) of 36.07. Vital statistics are analyzed in considerable detail. This annual report is made attractive by the use of organization charts, graphs and special cuts, with statistical data accompanied by descriptive text.

It is gratifying to note that over 98.8 per cent of the milk supply is pasteurized. Continued progress in the control of communicable disease is noted, including tuberculosis. In 1901, there was a tuberculosis rate of 169 as compared with 48 in 1928. In September, 1928, a tornado resulted in 14 deaths, with over 100 accidental injuries. City and county officials cooperated in public health, first aid and rehabilitation work following this catastrophe. A classified financial statement indicates an expenditure of $33,134 by the health department, in addition to expenditures by voluntary agencies whose coöperation is acknowledged.

New Brunswick Province—The 1928 report of this province is of special interest on account of the attention given to problems of mental hygiene, infant welfare, tuberculosis control, and a plan for county health units. Con-

siderable progress is being made in lowering the infant mortality and tuberculosis rates, and consideration is being given to the possibility of instituting a coöperative plan with the federal government for county health units. A comprehensive statement of health department activities is made by the medical officer, and this is followed by more detailed bureau reports which abound in well prepared statistical tables.

A birth rate of 25.5, a marriage rate of 7.0, and a death rate of 11.9 per 1,000 population are recorded. The infant mortality rate has dropped from 134.9 in 1920 to 96.0 in 1928. The estimated population of the province is 411,000.

Ottawa—This city, with a population of 122,731, reports for 1928 a birth rate of 24.8, a death rate (corrected) of 11.06, and an infant mortality rate of 104.07. Smallpox reached epidemic proportions during the last 2 months of 1927, and January of 1928, cases being chiefly among adults and preschool children. During 1928, there were 382 cases reported, with no deaths, 286 having been treated in hospital. Tuberculosis continued to decline, a death rate of 73 being recorded, 82 per cent of the deaths being of pulmonary form. The report contains many statistical tables, the analyses of vital statistics by age, sex, and nationality being of special interest.

Pennsylvania Milk Inspectors—To health officers and milk control officials, the 224-page report for 1929 of the Pennsylvania Association of Dairy and Milk Inspectors will prove valuable. Papers deal with bovine tuberculosis eradication work, undulant fever, arrangement and remodeling of dairy barns, clean and safe milk for small communities, heat-resistant and heat-loving bacteria, coöperation between states regarding conditions surrounding the production of milk for interstate shipment, recording thermometers, ordinances, and pasteurization problems.

Lorain County, O.—Printed on good paper, with a soft green, well designed cover, this 1928 report for a county health district of 33,571 inhabitants occupies 41 pages. In a foreword, the health commissioner outlines important features of the district and its health organization. This district comprises 10 villages and 20 townships, with a land area of 476 square miles. In addition to the board of health of 5 members, there is a district advisory council, which consists of the mayors of the 10 villages and the chairmen of the boards of trustees of the 20 townships. Besides the medical health commissioner, the personnel consists of a deputy commissioner, a part-time school physician, 3 public health nurses, a bacteriologist-chemist, and a clerk. The budget, as shown by a classified statement, amounts to 58 cents per capita.

A crude death rate of 12, a birth rate of 14.9, and an infant mortality rate of 48.1 are recorded for the year. As considerable toxin-antitoxin work had been done, it was decided to perform Schick tests on a group of 1,789 school children. Of 1,046 who had received 3 or more T–A injections, 77.6 per cent gave negative Schick tests, while of 671 who had received no injections, 30.7 per cent gave negative results. There were 72 children who had received one or two injections, and of these 59.8 per cent gave negative reactions. The intervals between last injections and Schick tests are not stated.

Among the outstanding features of the year are noted the following: Six employees traveled over 50,000 miles in connection with the work. Three nurses made 28,800 inspections of school children, and 2,898 visits of various kinds to homes and schools. The

bacteriologist analyzed 3,194 specimens and made 189 dairy farm and milk plant inspections. Over 49,000 pieces of mimeographed material were distributed by the department, and 94 health talks were given to Parent-Teacher organizations and civic clubs, in addition to 539 health talks to school groups.

Tennessee—One of the best state health department reports received this year is that of Tennessee for 1926–1927. The report opens with an enlightening statement regarding general policy, and the responsibility of state and county governments.

> There is, therefore, no more fundamental responsibility of government, considered from the economic point of view only, than the responsibility to serve and to protect the public health. . . . The State Department of Public Health in Tennessee is committed to a policy which recognizes local responsibility for public health activity and that the health program for the state as a whole must be built on a solid foundation of well organized, effective local full-time health departments organized under trained leadership and manned by trained personnel.

Extension of local rural health work through full-time county departments is being stimulated.

A second major element is that the state department shall so organize its own activity as to render expert consultant service to local departments of public health and act as a coördinating influence in the development of a common program of activity and high standards of service for local health agencies. A third element provides for leadership rather than compulsion, and a fourth for a recognition of the fundamental contribution to public health progress which can be made by the practicing physician.

Following a summary of health conditions, the report takes up the work of various divisions, including administration, local organization, epidemiology, vital statistics, laboratories, sanitary engineering, child hygiene and public health nursing, and health education. This most important phase of public health work (health education) is now receiving due attention by the department. A director has been secured and educational material covering all subjects pertaining to public health has been prepared. Plans are under way for the coördination and further extension of health instruction in the educational institutions of the state. The attractiveness of the report is increased by the careful preparation and selection of good statistical tables, charts, and photographs, which add interest to the text.

BOOKS RECEIVED

THE MODERN BABY BOOK AND CHILD DEVELOPMENT RECORD. By John E. Anderson and Florence L. Goodenough. New York: Norton, 1929. 398 pp. Price, regular ed. $5.00; de luxe ed. $10.00.

REGIONAL PLAN OF NEW YORK AND ITS ENVIRONS. Vol. VIII. Physical Conditions and Public Services. New York: Committee on Regional Plan of New York and its Environs, 1929. 209 pp. Price, $3.00.

CHEMISTRY IN DAILY LIFE. By Samuel Glasstone. New York: Dutton, 1928. 250 pp. Price, $2.25.

RICKETS, INCLUDING OSTEOMALACIA AND TETANY. By Alfred F. Hess. Philadelphia: Lea & Febiger, 1929. 485 pp. Price, $5.50.

THE CHALLENGE OF CHRONIC DISEASES. By Ernst P. Boas and Nicholas Michelson. New York: Macmillan, 1929. 197 pp. Price, $2.50.

THE CHILD'S HEREDITY. By Paul Popenoe. Baltimore: Williams & Wilkins, 1929. 316 pp. Price, $2.00.

HEREDITY AND PARENTHOOD. By Samuel C. Schmucker. New York: Macmillan, 1929. 322 pp. Price, $2.50.

INCAPACITY OR DISABLEMENT IN ITS MEDICAL ASPECTS. By E. M. Brockbank. London: Lewis, 1926. 120 pp. Price, $2.00.

COMMUNITY RECREATION. By James Claude Elsom. New York: Century, 1929. 278 pp. Price, $2.25.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Before and After in Mental Hygiene—What people used to think and what they are now beginning to realize in child training are interestingly contrasted.

ANON. Old and New Version of Child Training, Ment. Hyg. Bull., 7, 6: 4 (June), 1929.

Progress in Nutrition—Another of Dr. Burnett's invaluable summaries of the work in nutrition throughout the preceding year. Excellent source material, especially for writers in this branch of health work.

BURNETT, F. L. Progress of Nutrition, New England J. Med., 200, 26: 1329 (June 27), 1929.

Preventing Tuberculosis with BCG—An answer to the statement that BCG may be virulent made by Petroff *et al.* Petroff's methods are questioned and his conclusions contradicted. Finally, the immunization of exposed infants is urged. Very emphatic throughout.

CALMETTE, A., and PLOTZ, H. Protective Inoculation against Tuberculosis with BCG, Am. Rev. Tuberc., 19, 6: 567 (June), 1929.

Maternal Mortality—That the problem of preventing needless maternal mortality is insistent everywhere is evidenced by this British discussion. What is done in that country is recounted, and the need of educating the public is stressed.

CASSIE, E. Maternal Mortality and Allied Problems, Pub. Health, 42, 10: 329 (July), 1929.

Infant Growth—The effect of cod liver oil added to diet suggests that the accepted standards of infant growth are too low.

DANIELS, A. L., *et al.* The Relation of Rate of Growth in Infants to Diet, Am. J. Dis. Child., 37, 6: 1177 (June), 1929.

Cancer, Urban and Rural—That *recorded* cancer deaths are probably lower in rural than in urban areas (after due correction for age composition of the population) is the conclusion of this interesting study of cancer mortality statistics in New York State.

DE PORTE, J. V. Extent to Which Residence Influences the Recorded Death Rates from Cancer in the State of New York, Am. J. Hyg., 10, 1: 201 (July), 1929.

School Room Ventilation—All who want to keep up-to-date on the school-room ventilation question will read with interest this latest statement of the secretary of the New York Commission.

DUFFIELD, T. J. The New York Commission on Ventilation. Quart. Bull. (Milbank Memorial Fund), 7, 3: 67 (July), 1929.

Urban vs. Rural Health—Relative changes in death rates urban and rural, and some of the probable causes are very interestingly presented.

EMERSON, H., and PHELPS, E. B. The City Gains on the Country, Survey Graphic, 42, 9: 469 (Aug. 1), 1929.

Undulant Fever—Another summary of our present-day knowledge of undulant fever, and a good one.

HASSELTINE, H. E. Current Studies in Undulant Fever, Pub. Health Rep., 44, 28: 1659 (July 12), 1929.

Epidemiology of Paratyphoid—An inclusive consideration of the differential diagnosis, epidemiologic investigation

and control measures for the paratyphoid group.

JORDAN, E. O. The Epidemiology of Paratyphoid Infections, J. Prev. Med., 3, 4: 279 (July), 1929.

Cancer Clinics—A committee report on methods of improving the service for cancer patients. The pioneering work in Massachusetts is covered in the survey.

EWING, J., *et al.* The Medical Service Available for Cancer Patients in the United States, J. A. M. A., 93, 3: 165 (July 20), 1929.

Lead Poisoning—How lead poisoning occurs in a storage battery plant and how it can be prevented is the theme of this exhaustive report. Periodic physical examinations can forestall acute poisoning.

GREENBURG, L., *et al.* A Study of Lead Poisoning in a Storage Battery Plant, Pub. Health Rep., 44, 28: 1666 (July 12), 1929.

Enuresis—That enuresis is a conduct disorder which can be stopped when the child so desires is the postulate of this paper. Other treatment than that of making the patient assume his responsibility is against the child's interest. Read it.

HAMILL, R. C. Enuresis, J. A. M. A., 93, 4: 254 (July 27), 1929.

Health Education for Children—The health educational methods employed in the Bellevue-Yorkville demonstration district cannot be summarized here, but that is unnecessary, for this paper will be read by all interested health workers.

LAMKIN, N. B., and DU PAUL, M. E. Health Education in Schools in the Metropolitan Health Demonstration Area, Quart. Bull. (Milbank Memorial Fund), 7, 3: 53 (July), 1929.

Body and Mind—One broad conclusion of this comprehensive study of Illinois children is that the number of physical defects decreases and the physical condition improves with the increase in the height of the I. Q. The authors wisely do not try to interpret this relationship.

KEMPF, G. A., and COLLINS, S. D. A Study of the Relation between Mental and Physical Status of Children in Two Counties in Illinois, Pub. Health Rep., 44, 29: 1743 (July 19), 1929.

Meat Diets—Two subjects (former arctic explorers) lived on an exclusive meat diet for a year with no ill effects—in fact, one subject's hair stopped falling out. Vegetarians take notice.

LIEB, C. W. The Effects on Human Beings of a Twelve Months' Exclusive Meat Diet, J. A. M. A., 93, 1: 20 (July 6), 1929.

Tuberculosis Immunization—Another paper upholding Calmette's claim that exposed children may safely be immunized against tuberculosis with BCG.

MAGUIRE, W. J. Early Immunization as a Preventive Measure against Tuberculosis, J. State Med., 37, 7: 421 (July), 1929.

Diphtheria in Palestine—The apparent absence of diphtheria combined with a high immunity rate can be accounted for only on the assumption that the disease is so mild as to be unrecognizable. Why the disease is not detected is being investigated. Very interesting.

MANN, M., and KLIGLER, I. J. The Schick Test in Palestine, a Country of Low Diphtheria Prevalence, J. Prev. Med., 3, 4: 309 (July), 1929.

Infant Mortality Causes—After scrutinizing the conditions within and without the infant which influence his ability to overcome the first year's hazards, the author proceeds to dissect the typical child hygiene program. Good for the soul.

SMITH, R. M. The Important Causes of Infant Mortality. Child Health Bull., 5, 4: 97 (July), 1929.

Endemic Typhus Fever—As there is endemic in the United States a disease resembling typhus which is not compatible with louse transmission from man to man, it must be that it is spread from some other source, probably some rodent, by a blood sucking parasite. An interesting speculation.

MAXCY, K. F. Typhus Fever in the United States, Pub. Health Rep., 44, 29: 1735 (July 19), 1929.

Meningitis Control Measures—An honestly pessimistic summary of experience in attempting to prevent the spread of this disease ending with the quotation from Rosenau that no measures so far taken have materially influenced the course of epidemics or prevented the spread of meningitis.

MCCOY, G. W. Meningococcus Meningitis and Measures for Its Control, Pub. Health Rep., 44, 27: 1595 (July 5), 1929.

Growing Bacteria—A method of growing bacteria in continuous culture was perfected for the production of large quantities of bacterial products. An ingenious apparatus.

MOYER, H. V. A Continuous Method of Culturing Bacteria for Chemical Study, J. Bact., 18, 1: 59 (July), 1929.

Industrial Hygiene—The record of the medical department of a small factory. All employees submitted voluntarily to the offered health examination, and 31 per cent of the discovered defects were corrected within the year.

MURRAY, H. G., and COOLIDGE, E. Health Work in Industry, New England J. Med., 200, 26: 1321 (June 27), 1929.

Reporting Children's Diseases—This supplementary report of the Hagerstown Morbidity Studies indicates that age is an important factor in completeness of reporting of children's diseases. It is suggested that morbidity statistics be used cautiously.

SYDENSTRICKER, E., and HEDRICH, A. W. Completeness of Reporting of Measles, Whooping Cough, and Chickenpox at Different Ages, Pub. Health Rep., 44, 26: 1537 (June 28), 1929.

Seasonal Diphtheria Immunity—The findings of an investigation which the authors believe tends to strengthen the probability that the fundamental factor in seasonal variation in diphtheria is the modification of individual resistance.

PERKINS, R. G., *et al.* Seasonal Variation of Diphtheria Antitoxin Content of the Blood of Adults and Adolescents, Am. J. Hyg., 10, 1: 13 (July), 1929.

Diet for the Aged—This paper should be read not only for the valuable lesson in applied common sense but because of the injection of the human touch—for lack of a better word—into technical writing.

RICE, T. B. A Balanced Ration for the Aged, Pub. Health Nurse, 31, 7: 356 (July), 1929.

Practitioners and Health Education—General practitioners are urged to participate in the health educational campaign in this rather rambling but none the less interesting discourse on public instruction in medicine.

ROBEY, W. H. Public Instruction in Medicine, New England J. Med., 200, 25: 1271 (June 20), 1929.

The Tuberculosis Patient—This appears to be the complete report of the study made to determine how much medical attention the early case of tuberculosis gets. Mention of the findings has been made in earlier papers. The need for periodic examinations of the apparently well is stressed.

WILLIAMS, L. R., and HILL, A. M. A Study of What Tuberculosis Patients Experience Prior to Their Admission to a Sanatorium, New England J. Med., 201, 2: 82 (July 11), 1929.

NEWS FROM THE FIELD

SNAKE BITE SERUM

THE New York State Health Department has distributed throughout the state a limited supply of antivenin serum for use in an emergency. This serum is used in case of bites from rattlesnakes, copperheads and water moccasins.

The supply is available at the State Laboratory at Albany; Bear Mountain headquarters of the Palisades Interstate Park, and at the district laboratory supply stations at Glens Falls, Binghampton and Haverstraw.

The department stated:

> Immediate administration of the serum is urged, and is probably essential, although it is said to be effective if given within from 12 to 24 hours after the bite.

"RABBIT FEVER" RECOGNIZED AS EXISTING IN RUSSIA

PROOF that tularaemia or "rabbit fever" is by no means confined to the United States is given in a report received by the U. S. Public Health Service which indicates the prevalence of the disease in Russia. The full text of a statement by the U. S. Public Health Service dealing with this subject and made public June 22, 1929, follows:

> That tularaemia is by no means confined to the United States is shown by a recent article in a foreign scientific journal which carries abstracts of articles which would indicate that tularaemia is coming to be recognized as existing in Russia. The original articles are by members of the staff of the State Institute of Microscopy and Epidemiology, at Saratov, for the S. E. of the Union of Socialistic Soviet Republics.

INSTITUTE FOR TUBERCULOSIS WORKERS

VANDERBILT University, in cooperation with the National Tuberculosis Association, will conduct an Institute for Tuberculosis Workers from September 10 to 24, 1929, at Nashville, Tenn. The Southern Conference on Tuberculosis, the Tennessee Tuberculosis Association and the Tennessee State Department of Health will also cooperate in this Institute.

> The Institute has four main objectives: to assist workers already in executive positions in the tuberculosis field to assume positions of great responsibility or to become more useful in their present positions; to prepare for executive positions those who have not had experience in the tuberculosis field; to give to volunteer workers a more comprehensive knowledge of the administrative problems involved in this work; to aid in the standardization of methods and programs of tuberculosis work.

MILK

ROME, Naples, Milan, and Verona have established milk centers where all milk intended for consumption in the city is sent for sterilization. At Italy's first conference on milk, held recently in Verona under government auspices, the fact was brought out that the annual consumption of milk per capita in Italy is only 15 quarts, while it is 90 quarts in England, 235 quarts in Germany, and 265 quarts in Sweden.

MENTAL HYGIENE CONGRESS

THE First International Congress on Mental Hygiene will be held in Washington, D. C., May 5 to 10, 1930. Twenty-six countries are already represented on the Committee on Organization, of which Arthur H. Ruggles, M.D., of Providence, R. I., is chairman.

Questions to be discussed at the Congress will include the relations of mental hygiene to law, to hospitals, to education, industry, social work, delinquency,

parenthood and community problems. A world-wide view of mental hygiene progress will be given.

It is the contention of those promoting the Congress that mental hygiene has to do with the conservation of mental health in general, not merely with nervous and mental disorders and diseases.

A NEW HEART LEAFLET

THE importance of physical examinations, the prevention of heart defects, and suggestions about how to live with an impaired heart are all included in a brief leaflet *Your Heart*. This is one of the health leaflet series issued free to health agencies by the Life Conservation Service of the John Hancock Mutual Life Insurance Company, Boston, Mass.

BROOKLYN, N. Y., BOYCOTTS LOOSE MILK

GRADE B milk in all parts of Brooklyn, N. Y., with the exception of East New York, has recently been boycotted. This was announced by Daniel Gutman, counsel for the Greater New York Grocers' and Dairymen's Protective Association.

SUN-TAN

SHIRLEY W. Wynne, M.D., Commissioner of Health of New York City, warned the people recently, in a speech he gave over the radio, against getting too bad a sunburn for the sake of style. He said:

When a person in the sun gets a peculiar sort of headache, becomes dizzy or nauseated, or notices that his skin is hot and dry, and that he is not perspiring as usual, it means that he must get out of the sun—and get out of it at once. If he pays no attention to these warnings, he will suddenly become unconscious and drop in his tracks.

The treatment in such a case, Dr. Wynne contended, is to call in a doctor, bring down the temperature of the patient by means of ice water, ice packs, cold showers, ice bags and cool sponges. He must rest for several days, avoiding the sun.

COMMONWEALTH FUND

THE Commonwealth Fund, which completed on June 30 a 5-year program for the development of child health services in Austria, announces the adoption of a new plan, to be put in operation on January 1, 1930, to promote rural health and medical service in the United States.

Unlike the Austrian project and the 4 child health demonstrations which the Fund has conducted in North Dakota, Tennessee, Georgia, and Oregon, the new undertaking will not stress child care. Its purpose will be rather to explore the possibility of bettering the whole range of health services in rural communities.

The Fund will center its effort in 2 states, yet to be selected, and in 2 counties or districts in each state where a sound beginning has already been made in local public health organization.

PERSONALS

PROFESSOR THOMAS WALTON GALLOWAY, member of the Division of Educational Measures of the American Social Hygiene Association, died on July 16, in New York, N. Y.

DR. WADE HAMILTON FROST, Surgeon of the U. S. Public Health Service, resigned from the Service. His resignation is effective beginning August 8, 1929.

GEORGE W. BARTELMEZ, Ph.D., has been promoted to a full professorship in anatomy at the University of Chicago, Chicago, Ill.

JACOB T. BUTZ, M.D., health officer of Allentown, Pa., has been elected President of the Pennsylvania Public Health Association.

DR. LESLIE ERNEST FUCHS, of Vienna, Austria, will be awarded the Leslie Dana Gold Medal for 1929, according to an announcement made by Lewis H. Carris of the National Society for the Prevention of Blindness.

DR. CHARLES MAYO, of Rochester, Minn., was awarded the degree of doctor of science, on June 23, at Leeds, England.

DR. JAMES L. MCCARTNEY has been appointed psychiatrist of the Connecticut State Department of Health.

DR. MARION LECOCQ, Lynden, Wash., has been reappointed County Health Officer, to serve a term of 2 years.

ISIDORE S. FALK, Ph.D., has been promoted to a full professorship in hygiene and bacteriology at the University of Chicago, Chicago, Ill.

CONFERENCES

Sept. 26–28, Association of Military Surgeons of the United States, Denver, Colo.

Sept. 30–Oct. 5, American Public Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, American Child Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, International Society of Medical Health Officers, Minneapolis, Minn.

Sept. 30–Oct. 5, American Association of School Physicians, Minneapolis, Minn.

Sept. 30–Oct. 5, Northwest Conference of Child Health and Parent Education, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Sanitary Conference, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Public Health Association, Minneapolis, Minn.

Sept. 30–Oct. 5, Minnesota State Organization for Public Health Nursing, Minneapolis, Minn.

Sept. 30–Oct. 5, American Social Hygiene Association, Minneapolis, Minn.

Sept. 30–Oct. 5, Conference of State Laboratory Directors, Minneapolis, Minn.

Streptococcus of Septic Sore Throat*

WILLIAM D. FROST, DR. P. H., FELLOW A. P. H. A., R. C. THOMAS, MILDRED GUMM, AND MYRTLE SHAW, PH. D.

Laboratories of Agricultural Bacteriology, University of Wisconsin, Madison, Wis.

SINCE the first great American epidemics, which appeared in Boston in 1911 and Chicago in 1912, septic sore throat has been the subject of vital interest both to public health officials and to milk producers the country over. This is especially true because septic sore throat, even now, is erroneously quite generally regarded as an exclusively milk-borne disease.

Before this disease was recognized in its epidemic form in this country, it was well known in England and the Scandinavian peninsula.

Wherever and whenever the disease has appeared, streptococci have always been recognized as the probable etiological factor, but it was not until the work of Davis[1] in 1912 that a specific streptococcus was incriminated. His bacteriological study of this organism made it clear that the streptococcus of septic sore throat in the epidemics he studied differed in certain quite striking particulars from the hemolytic streptococci commonly found in tonsillitis and various other human infections. The value of Davis's work in thus differentiating the streptococcus of septic sore throat was not immediately recognized; in fact, even recent literature contains statements to the effect that the type of streptococcus may vary in different epidemics.

Brown, Frost and Shaw[2] in 1925 examined, by critical and differential methods, all of the cultures isolated from epidemics of septic sore throat, including the Boston and Chicago ones, so far as they were available. Their conclusions were that all of the various strains

* Read before the Laboratory Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

studied, some 11 in all, were identical so far as their tests showed; and that they corresponded with the organism originally described by Davis and named by him *Streptococcus epidemicus*. They also re-emphasized the fact that this streptococcus differs very strikingly and constantly from *Streptococcus pyogenes* in two major particulars, namely, that *Streptococcus epidemicus* possesses a striking capsule when examined in moist India ink preparations, and that its colonies are large, and moist, and have a tendency to grow on the surface.

DESCRIPTION OF STREPTOCOCCUS EPIDEMICUS

From the work that has been done on this organism[3] it may now be described as a streptococcus growing in short or long chains, surrounded—when viewed in a moist India ink preparation—by a capsule, the entire width of which is, on the average, equal to 3 of the organisms. This capsule, however, is not stained by the ordinary capsule stains.

On poured blood agar plates the colonies reach considerable size in 18 hours, and between 24 and 48 hours present their most characteristic appearance. In general, streptococcus colonies grow below the surface of the medium and are spherical or slightly lenticular in shape. Rarely small, thin colonies appear on the surface. But *Streptococcus epidemicus* colonies characteristically appear as surface colonies. They are large, moist and spreading, and to the uninitiated might not be recognized as streptococcus colonies at all. These surface colonies have a marked tendency to dry down if their incubation is prolonged beyond 48 hours. The deep colonies are large, long and flatly lenticular.

The colonies on a standard blood agar plate are strongly hemolytic, producing a clear hemolyzed area in from 24 to 48 hours, from 2.5 to 3.0 mm. in diameter. Twenty-four hours later this area may be nearly doubled in size.

In fluid mediums it produces complete hemolysis in 2 hours when tested by the U. S. Army method.[4]

When inoculated intraperitoneally with ½ c.c. of a 24-hour serum broth culture, it kills mice in from 7 to 48 hours.

This organism ferments dextrose, lactose, saccharose, and salicin, but not mannite. In dextrose broth it produces a pH not lower than 4.8. It does not ferment inulin or raffinose and is not bile soluble, but these tests probably have little or no value in differentiating streptococci. The same is true of cultures in broth and milk. This organism does not hydrolyze sodium hippurate as many of the bovine strains do.

THE CLINICAL ASPECTS OF SEPTIC SORE THROAT

It should, we think, be emphasized that this is a distinct disease, which etiologically, clinically and pathologically can be recognized as an entity; that public health officials should recognize it as a distinct communicable and reportable disease and urge the physicians in their constituencies to take the possibility of this disease into consideration when they are called to treat cases of severe sore throat, especially in adults, and also to bear in mind the possibility of confusing this disease with atypical cases of scarlet fever and influenza. It seems certain that sporadic cases of septic sore throat frequently and continuously exist. So far as we are aware, there is no literature on this phase of the subject.

EPIDEMICS OF SEPTIC SORE THROAT

From 1880 to 1905 there were described 18 epidemics in England, 1 in Norway in 1908, and, since the first epidemic in this country at Cambridge, Mass., in 1908, 52 in the United States reported as being milk-borne.[5, 6] One hospital epidemic has been described as being spread by contact,[7] and recent reports from the Massachusetts State Board of Health[8] have recognized an increasing number of cases of septic sore throat not milk-borne.

In the light of our present knowledge, the causal relationship of milk to streptococcic sore throat has been satisfactorily demonstrated in comparatively few American epidemics, although there is little reason to doubt that, if what we now regard as the proper bacteriological methods had been used in their study, the epidemiological relationships would have been made clear in most if not all of them.

ETIOLOGICAL RELATIONSHIPS

There are commonly found in milk, pasteurized as well as raw, streptococci which upon a cursory examination might be confused with the etiological agent of this disease. It is even now a common practice in medical literature to refer to all hemolytic streptococci as *Streptococcus hemolyticus* on the supposition that they are all the same. As very clearly pointed out in his admirable monograph on the use of blood agar for the study of streptococci, J. Howard Brown makes it clear that hemolysis is a property common to very different streptococci, which may be separated into several quite distinct types or species. Unless, then, in the discussion of any epidemic of septic sore throat it is actually shown that *Streptococcus epidemicus* is present, the investigations have little value.

The presence of hemolytic streptococci in raw milk, in interepi-

demic periods, has been studied by a number of investigators. Davis,[9] for example, found hemolytic streptococci in 85 out of 328 samples, or approximately 26 per cent of those examined. Ayers and Mudge[10] isolated streptococci from 38 per cent of the cows examined by them, but did not indicate their action on blood. Frost and Bachmann[11] examined individual samples from 412 cows and found hemolytic streptococci of the beta type in 28 per cent of them. The mere presence of hemolytic streptococci in milk can have no significance in the epidemiology of septic sore throat, since they are always found in high grade raw milk; frequently found in pasteurized milk; and we believe they are quite as common in the poorer grades of raw milk, although there is considerable difficulty in demonstrating them due to the fact that other bacteria present make it necessary to dilute the sample far beyond that point which is ordinarily used in demonstrating them in the better grades of milk.

In the investigations of many of the past epidemics of septic sore throat, the finding of a cow suffering from streptococcic mammitis has been taken as sufficient evidence of the fact that the milk from such a cow was the cause of the epidemic, but we believe that there is no evidence that ordinary bovine mastitis is the cause of septic sore throat—or any human disease for that matter. The cause of mastitis in cattle is not always streptococci, but, even when it is, these are very rarely of the "epidemicus" type, and hence cannot be the cause of the disease. Furthermore, mastitis in cattle is such a common disease that it would be difficult to associate septic sore throat, which occurs so rarely, with this disease in cattle, which is so commonly and universally present.

To account for milk-borne septic sore throat, it is necessary to assume that the causal organism is present in the particular milk in quantities sufficient to infect.

It is quite evident that this organism may enter the milk in two ways. It may get into the milk from the milker or others who handle it, after it is drawn from the cow, or it may come directly from cows suffering from a mastitis caused by *Streptococcus epidemicus*, or from cows which are, at least, carriers of this organism. The relative importance of the probable source of this organism in milk has been ably discussed by previous workers, especially Smith and Brown,[12] in which they come to the conclusion:

> The grafting of human streptococci upon the udder, their multiplication under ideal conditions in the warm fresh residual milk, and their discharge twice daily into the milk at milking time, offers a much better explanation of the continuance of milk-borne epidemics over a number of days than any single infection of the

milk through coughing, sneezing, spitting, and tasting. Such accidents may indeed infect the milk, but the infection could hardly last over a day and might be diluted to ineffectiveness in a very large supply. Such accidents would be more potent in a very small dairy.

We may add that such accidents could not logically be thought of as the cause of large epidemics.

"EPIDEMICUS COWS"

For a period of about 4 years the authors have been taking regular monthly samples from the 8 herds (about 1,200 cows), supplying the Chicago district with certified milk, and typing the streptococci in an effort to determine whether *Streptococcus epidemicus* was present, and, if so, its source. Our method of procedure has been to milk a string of 10 cows into a 2-ounce bottle. In doing so, we have discarded the first stream of milk from each quarter and collected the second. These samples have been iced and sent to the laboratory as soon as possible. From the more distant farms this has sometimes been an overnight journey. Each composite sample has been diluted 1 to 20 and plated in veal infusion agar to which 7 per cent of defibrinated horse blood has been added. The incubation temperature has been 37° C. and the time from 18 to 48 hours. If suspected streptococci are found in any of these composite samples, samples from the individual cows composing the string in question are taken and examined by the same routine.

It has been found that streptococci which give a beta zone of hemolysis are very common in these samples, and under the old term would have been regarded as *Streptococcus hemolyticus*. By applying the various tests mentioned in the description of *Streptococcus epidemicus* above, it has been found that there are 4 types or species into which these beta hemolytic streptococci can be classified. In the order of the frequency with which they occur they are: *Streptococcus mastitidis, Streptococcus infrequens, Streptococcus asalignus,* and a small unnamed group differing only slightly from the last. None of these streptococci would be readily confused with *Streptococcus epidemicus.* They are without doubt of bovine origin and are apparently only infrequently connected with mastitic disturbances. They appear to live on the milk rather than on the tissue of the udder.

We have occasionally found *Streptococcus epidemicus* in our group samples, and have been able to identify the cows shedding them. In all we have seen and studied more or less completely 17 cows. Eight of these were found in certified milk herds supplying the Chicago district; 2 were found in connection with an epidemic of septic sore throat (Frost and Carr[15]); and the other 7 were discovered from time to time

as samples of milk were referred to us from the Veterinary Science Department of the University of Wisconsin. In the 8 cows found on the certified milk farms 1 was suffering from a clinical mastitis at the time of discovery and 2 others, which were under study a considerable period of time, later developed pathological conditions which would probably have been recognized by a clinical examination. It is very evident from our work that by means of this monthly examination we are able to pick out cows which may be shedding *Streptococcus epidemicus* in large numbers, which would not have been excluded from the herd, for a considerable time at least, by even the most careful clinical examination. In most of these "epidemicus" cows, there was such a slight abnormality in the udder and the milk that it had escaped the attention of the milkers even though a stripping cup was used.

So far as the 8 cows of the certified milk herds were concerned, they had all recently been brought to the farms, and we have no knowledge of how they became infected. We were unable to obtain any data on the 7 other cows, but the 2 concerned with a small epidemic of septic sore throat were associated with a milker in whose throat we found *Streptococcus epidemicus.*

In regard to the quarters infected, in 4 of the 17 it was undetermined; in 7, only one quarter; in 4, two quarters; and in 2, three quarters of the udder were infected.

We have gone on the supposition that the source of infection was from man, and since Davis has shown that in his experimental work an injury to the udder tissue was necessary for infection, it was interesting to note that a considerable number of these cows had either sores or scars on their teats or udders.

EXAMINATION OF EMPLOYEES' THROATS

To guard against the possibility of cows becoming infected on the certified milk farms, as well as to protect the milk from infected handlers, a monthly examination of throat swabs from the employees on all the farms in the Chicago district for *Streptococcus epidemicus* has been carried on simultaneously with the examination of the milk samples. The examinations are made in the same way. The swabs are covered with about 2 c.c. of veal infusion broth, either at the farm or as soon as they are received at the laboratory. In the latter case they are incubated for about 2 hours, and then a single loop of this broth is introduced into a tube of fluid blood agar and poured into petri dishes, so that we are able to get the same poured plates as in the milk samples.

The results obtained during the first 2 years were reported by Dr.

Clarence C. Saelhof.[14] During the latter half of the period covering 20 months, 1,996 cultures have been examined from 438 different men. Of these about one-fourth, or 115 men, were carrying streptococci which gave beta hemolytic colonies. Fourty-four men gave these cultures with such regularity that they might be considered as carriers. The remaining 72 gave positive results only occasionally.

There have been 7 different types of beta hemolytic streptococci found: *Streptococcus pyogenes* in 66 men, *Streptococcus anginosus* in 35, *Streptococcus mastitidis* in 17, *Streptococcus equi* in 8, *Streptococcus subacidus* in 7, *Streptococcus infrequens* in 6, and *Streptococcus epidemicus* in 6.

Streptococcus epidemicus has been identified in the throats of 3 men by Saelhof and in 6 by us. In only 1 man, however, has it been possible to obtain more than the first culture because, with this 1 exception, the men have left the farm upon hearing of the results. In the 1 case mentioned we were able to get several cultures. He was immediately sent off the farm and visited by a physician who made the cultures. He had a clinical sore throat but it was never diagnosed as septic sore throat. After recovery, his tonsils were removed and later several cultures were made which were all negative. He was allowed to return to the farm, but was observed on two occasions going to his room when the doctor visited the farm for the purpose of making swabs and gargling his throat. For this attempted evasion of an examination, he was promptly discharged, but soon reappeared on another of our certified milk farms, in another state. Two examinations from him at this place were negative, but as soon as his identity was discovered, he was again discharged. We have never found *Streptococcus epidemicus* in the milk of either of the farms where this man worked, nor have we ever found "epidemicus cows" on the farms where *Streptococcus epidemicus* has been found in the throats, with 2 exceptions, where the cultures from the throats were obtained a year or more after the infected cows were found.

HOW SAFE DO THESE TESTS MAKE RAW MILK?

The facts determined in these investigations suggest that the methods proposed, largely by Brown and his coworkers, enable us to differentiate human hemolytic streptocci of the beta type from those commonly found in milk.

The *Streptococcus epidemicus* cultures which we have occasionally found in milk correspond in all particulars with the cultures of this organism from the various human epidemics from which cultures are available.

These cultures of *Streptococcus epidemicus* have always been traced to particular cows which we were able to identify promptly and remove. So far as our evidence goes, these cows have always been infected with this organism, and were not merely furnishing in the milk cistern of the udder the culture medium. They have been found in all stages of infection. On the certified milk farms we have always detected them in the early stages, and 6 of the 8, when first found, showed no clinical symptoms of mastitis or detectable changes in the fresh milk, but such of these cows as we have been able to study have later developed mastitis which led to profound tissue changes. It would seem that cows suffering from an infection with a human streptococcus are not by any means rare, at least in certain dairy sections of the country. There may be, for example, a large number of these cows in the dairy regions of Massachusetts, New York and Connecticut, where 41 of the 52 epidemics of septic sore throat in this country have appeared, while only 3 have been reported from Illinois, 2 each from Vermont and Wisconsin, and 1 each from Maryland, New Hampshire, Oregon and Pennsylvania.

Granting that our method of examination is as satisfactory as it appears to be in our hands, and granting that certified milk farms do not introduce cows into their milking lines unless they have been shown to be free from infections with *Streptococcus epidemicus,* or carriers of this organism, and granting further that by throat examinations of the milkers and dairy employees to be sure that they are not harboring this organism, and providing that the milk from individual cows or small groups be examined on blood agar plates at frequent intervals to detect dormant carriers, it would seem that the danger of milk-borne septic sore throat could be eliminated from such milk with a high degree of certainty.

Effect of Broken Home on Quality of School Work

IN a study of 4,000 public school children in Germany, most of them 10 to 14 years old, the author, who some time ago made a study of the effect of economic condition on the quality of school work, concludes that the absence of one or both parents has an unfavorable effect on the child's school work.

The author finds that retardation, that is, failure to be promoted, is 50 per cent more frequent among children from incomplete families than among children from normal families. (An incomplete family is one that has been disrupted by the death of one or both parents or by divorce, or in which the mother is unmarried.) Particularly bad was the situation among children who had lost their fathers, among whom retardation was 70 per cent more frequent than among children having both parents.

In seeking the causes of this situation the author takes up the relative importance of inherited physical or mental inferiority and unfavorable environment in different types of cases. He is of the opinion that among children one or both of whose parents died at an early age inherited physical inferiority probably was a factor in the retardation. He thinks that inherited mental inferiority may have been present in the children of unmarried mothers, particularly when the mother had more than one child of illegitimate birth, and that children of divorced parents may have inherited certain defects that were responsible for the divorce of the parents. He finds that in every case lack of proper supervision, due to the absence of one or both parents, had affected the quality of the child's school work.—*Zeitschrift für Kinderforschung*, Berlin, 33, May 22, 1929, p. 517.

Endemic Goiter in Louisville and Jefferson County Schools

With Evidence of Family History, Defective Teeth, Tonsils, Chest Expansion, and Use of Iodized Salt

W. O. JOHNSON, M. D., F. A. C. S.
Louisville, Ky.

AMONG the profession as well as the laity, there seems to be an impression that endemic goiter is relatively infrequent in Kentucky, especially in the lowland counties, and that, when found, it is in families that have moved into those counties from goitrous belts.

In order to obtain some facts about the prevalence of endemic goiter in Louisville, Ky., a survey was made of the girls in Louisville city high schools and 8th grades, and of both boys and girls between 10 and 19 years of age in 9 schools in Jefferson County. Among a total of 5,083, there were found 677 cases of goiter; that is, 13.32 per cent of all examined had adolescent goiter. The work was done between February 1 and May 1, 1928.

All examinations were made by the same person in order that the findings might be comparable to others, and according to standards used by Olesen and Kimball. The goiters were recorded: very slight, slight, medium–large, and adenoma, following the classification by Kimball in the Akron survey. The usual methods of inspection and palpation were employed.

TABLE I

TYPES OF GOITERS

Types	City		County		Combined Total	
	Number	Per cent of all cases	Number	Per cent of all cases	Number	Per cent of all cases
Very slight	210	34.6	7	10.0	217	32.0
Slight	356	58.7	56	80.0	412	60.9
Medium–Large	29	4.8	4	5.7	33	4.9
Adenoma	12	1.9	3	4.3	15	2.2
Totals	607	100.0	70	100.0	677	100.0

Table I gives percentages based on the total number of cases examined in each separate group, for both city and county.

In this table it is interesting to note, 21.3 per cent greater incidence of slight adolescent or typical diffusely enlarged goiter in the county than in the city, and 2.4 per cent greater incidence of adenomata in the county. This may lead one to infer that either the type of life in the country has an effect, or that there is a greater familial incidence of goiter among the county cases than the city.

If there is a familial tendency, let us see if those that have goiters come from goitrous families or from goitrous districts.

TABLE II

RESIDENTS BORN OUT OF STATE

Type	City			County			Combined Totals		
	Born in the State	Born out of State	Total	Born in the State	Born out of State	Total	Born in the State	Born out of State	Total
Goiter.....	534	73	607	64	6	70	598	79	677
Per cent..	88.0%	12.0%	100.0%	91.4%	8.6%	100.0%	88.3%	11.7%	100.0%
Non-Goiter..	3,188	537	3,725	613	68	681	3,801	605	4,406
Per cent..	85.6%	14.4%	100.0%	90.0%	10.0%	100.0%	86.3%	13.7%	100.0%
Total cases..	3,722	610	4,332	677	74	751	4,399	684	5,083

There are 2.0 per cent more non-goiters born out of the state than goiter cases, while 3.4 per cent more goiter cases in the city were born out of the state than in the county.

It is interesting to note that 90 per cent of the goiter cases who were born out of the state and later moved into Kentucky were born in Indiana and Tennessee, which states are out of the goiter belts; while only 67 per cent of the non-goiters came from these states. This shows that cases of goiter found here arise, not from those who have lived in goitrous belts, but from native born families.

Table III clearly demonstrates the familial relationship of goiter; 22.1 per cent of the cases having a goiter gave a family history of goiter. Of these, in 60 per cent the mother had a goiter, and in 20 per cent a sister. Only 7.4 per cent of the non-goiters gave a family history of goiter, the mother being affected in but 46 per cent of this group. The family history of goiter is 10.4 per cent higher in the county schools than in the city schools. This throws some light on the findings in Table I, in which it appears that despite a more open air life and better hygiene in the country, there is a greater percent-

age of adenoma and definite adolescent goiter. Also, the familial relationship is greater in the county schools.

In this climate the average age for the beginning of menstruation is 13 years. It is before or about this time that adolescent goiter usually appears; in the goitrous district it appears much earlier.

Table IV shows that in the city 24.9 per cent of the goiters were found at age 15 years, which is later than the average beginning of adolescence in this climate, while in the county 21.4 per cent were found at the age of 13. There were 12.9 per cent more goiters found in the county at 10 years of age than in the city. None were found in the city at this age. The more rapid physical development of the country children may explain the earlier development of goiter in this group.

TABLE V

WEIGHT INCIDENCE

Totals	3,725	100.0	607	100.0	681	100.0	70	100.0

Children from 7 per cent overweight to 7 per cent underweight were considered within the normal zone. Only 40 per cent of those examined were within this zone, the group being about equally divided between the goiters and non-goiters. However, in the county schools, there were 16.9 per cent more non-goitrous children within the normal group than goiter cases.

The significant point is that in the city there were 4.3 per cent more goiter cases in the over 20 per cent undernourished group than non-goiter cases. In the county the ratio of goiters to non-goiters in the undernourished group is more pronounced. The greatest number of overnourished children were in the non-goiter group.

Dental conditions were classified as to tartar; tartar and cavities; and tartar, cavities and gingivitis; or extreme dental neglect.

The presence of dental decay does not necessarily imply focal infection, but it is reasonable to assume that focuses of infection are more possible with poor teeth than with good and well cared for teeth.

TABLE VI

Missing and filled teeth were not classified because of insufficient time, but one may assume that the usual reason why teeth were filled or removed was that they had been points of disturbance, though these steps may have been taken before systemic infection started. Missing teeth were more probably a cause of infection than filled teeth, for teeth are usually removed when they cannot be properly filled. These points as possible causes of thyroid enlargement will be discussed later.

There were 13 per cent more dental disorders among the goiters than among the non-goiters in the city, with only a 7.6 per cent greater number of dental defects between the two classes in the county. There were 9.7 per cent fewer dental defects among the goiters in the

TABLE VII

TONSILS

	City				County				Combined Total			
	Non-Goiter		Goiter		Non-Goiter		Goiter		Non-Goiter		Goiter

city than in the county. Can one explain this difference in the dental hygiene as due to more close attention to health habits in the city schools?

As only the girls were examined in the city, no comparison could be made there; but in the county the dental hygiene among the boys was 4 per cent higher than among the corresponding number of girls. The cases with larger goiters had the most extreme grades of dental neglect.

Tonsils are usually removed because of suspected or existing disease, and while enlarged tonsils do not necessarily indicate a source of infection, yet some of the enlargements may be the result of infections.

The classification of tonsils as: out, submerged, medium, and large, is to indicate degrees of hypertrophy, and not to infer that they are focuses of infection.

TABLE VIII

5	14	0.04	5	0.06	.....	.....	.....	.....	14	0.4	5	0.7
Totals....	3,725	100.0	607	100.0	681	100.0	70	100.0	4,406	100.0	677	100.0

There were 5.7 per cent more large cryptic tonsils among the goiters than among the non-goiters in the city, and only 1 per cent more large cryptic tonsils among the county goiter cases. The larger goiters were predominantly associated with large cryptic tonsils, and also the more severe grades of dental neglect. This association was a very striking feature throughout the survey.

In the city there were 4.3 per cent more tonsillectomies among the non-goiters than goiters, and 14.6 per cent more tonsillectomies in the

county goiter patients than the city school children. The removal of tonsils opens a large field for discussion as to whether the goiter is a result of preëxisting disease, or has occurred after tonsillectomy as a coincidence.

The chest expansion was measured one inch below the nipple line and a mean of two expansions taken.

The average chest expansion for the group is 2½ inches, slightly less than 1 inch less in goiter cases, in comparison to non-goiters. The chest expansion of county cases was not so great as of city cases, probably because of the difference in the mode of teaching and exercise; nevertheless the chest expansion of goiter cases was about 1 inch less than the non-goiter cases.

The use and non-use of iodized salt was recorded, for it has been advocated by some as a prophylactic.

TABLE IX

IODIZED SALT

	City				County				Combined Total			
	Non-Goiter		Goiter		Non-Goiter		Goiter		Non-Goiter		Goiter	
	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent

?.....	360	9.7	33	5.4	51	7.5	3	4.3	411	9.4	36	5.4
Total....	3,725	100.0	607	100.0	681	100.0	70	100.0	4,406	100.0	677	100.0

In the city 3 per cent more goiter than non-goiter cases were using iodized salt, and still there were 13.31 per cent goiters present. This is a greater incidence than was reported in a partial survey by Dr. L. K. Baldauf in 1925, in which approximately 7 per cent of goiter incidence was found.

There was 20 per cent less iodized salt used in the county than in the city, with 5.4 per cent fewer goiters in the county. This difference is not explained alone by the better hygienic life of the country child.

It seems from Table IX that iodized salt used as a prophylactic for adolescent goiters is only a mean of increasing sales of grocers' commodities to the credulous public when in reality it has not been proved to be of sufficient value to be called a prophylactic agent.

SUMMARY

A survey of 5,083 girls of Louisville city high schools and 8th grades, and boys and girls of 9 county schools, with 677 or 13.31 per cent adolescent goiter cases, found a predominance of adenoma and typical adolescent goiters in the county, with 10 per cent higher family incidence of goiter where, in spite of open, hygienic life, goiters develop when the family incidence is high.

These adolescent goiters came from local stock, and not from families of goitrous districts.

The family history is 14 per cent higher among goiters than non-goiters, and 20 per cent higher among the mothers of goitrous patients than non-goitrous, the condition appearing in mothers in 60 per cent and in sisters in 20 per cent of the cases.

The age predominance in Kentucky for adolescent goiter is somewhat higher than the beginning of adolescence, being on an average 14.6 years, and the county school children 1 year earlier.

Teeth without decay were more frequently found among non-goitrous children in both county and city. The county cases had slightly better dental hygiene than the city cases.

The extreme grades of dental neglect were more often found among those having the larger goiters.

Large cryptic tonsils were more often found among the goiter cases, and a greater number of non-goitrous children had had tonsillectomies than goiter cases.

Chest expansion of those with goiter averaged 1 inch less than those without.

Use of iodized salt was greater in the city, where goiter was 5.4 per cent higher than in the county where 20 per cent less iodized salt was used. Iodized salt does not seem to be efficient as a prophylactic.

COMMENT

From the above material it appears that goiters occurred more commonly among the undernourished children who had, to a greater extent, slight or markedly decayed teeth, as well as hypertrophied and cryptic tonsils, and with a chest expansion less than those with no goiter. These children were using 3 per cent more iodized salt to prevent goiter, but showed a greater incidence of goiter than the non-salt-users.

From the foregoing it appears that for the prevention of adolescent goiter more is necessary than the indiscriminate use of iodized salt.

We need a better public understanding of the problem, together with the institution of health habits, education, and individualized supervision of these adolescent goiter patients, not only for their better health but for the better health of future generations.

Contact Carriers in Meningitis*

JOHN F. NORTON, PH. D., FELLOW A. P. H. A.

Department of Health, Detroit, Mich.

IT is generally conceded that cerebrospinal fever (epidemic or meningococcic meningitis) is spread largely by healthy carriers. The control of the disease therefore depends upon the control of carriers. Measures leading to this end have been instituted under military conditions at various times in this country, in England, and in France. No attempt seems to have been made to control the movements of meningococcic carriers in a civilian population over any considerable period of time.

The number of cases of epidemic meningitis reported to the Department of Health in Detroit during the autumn of 1928 was unusually large.† In January, 1929, 66 cases (with 35 deaths) were reported as compared to an average of 3 for January of the 5 previous years. It appeared certain that an epidemic was in progress. Accordingly, the Commissioner of Health issued an order effective February 1, 1929, requiring the isolation of home contacts for a period of 14 days only, or until two consecutive nasopharyngeal cultures, taken not less than 24 hours apart, were found to be free from meningococci. Persons actually living in the apartment or house at the time the case was diagnosed as epidemic meningitis were considered contacts. In a few instances intimate or casual friends, who had been with the individual just before the illness began, have voluntarily requested that cultures be taken; but such persons when proved to be carriers were not officially isolated.

This report summarizes the experience in Detroit during the 6 months ending July 31, 1929.

Most of the cultures were taken by Department of Health nurses who were assigned to this work and carefully instructed. Some contacts came to the laboratory, but such a procedure was discouraged, particularly when street cars were used as means of transit. The cultures were taken from the nasopharynx with a swab on the end of a bent aluminum wire. The swab was then inserted in a sterile tube and placed in a towel between two warm water bags. Several calls

* Read before the Laboratory Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

† A complete report on epidemic meningitis in Detroit in 1928–1929 is in preparation and will be published later.

were made by each nurse before returning to the laboratory, and the warm water bags were refilled at each house. Upon reaching the laboratory the tubes containing the swabs were placed in an incubator and plated as soon as practicable.

The method described is not ideal, as is shown by the fact that about one swab out of seven failed to give growth on the culture medium, whereas when plates are inoculated immediately after taking material from the nasopharynx it is rare not to obtain growth of some organisms. We were unable to account satisfactorily for the difficulty. Addition of a little sterile distilled water to the tube containing the swab failed to correct this, so that drying of material was evidently not the cause. It was also found that frequently no growths were obtained from the cultures from persons who had recently gargled or were in the habit of using snuff or chewing tobacco. However, there were many more "no growths" reported than seemed desirable. Such a report was not regarded as a negative result for meningococci, and another culture was taken.

The medium used for growing the organisms was that generally recommended—meat infusion peptone agar of pH 7.6, containing 1 to 2 per cent of dextrose and 5 per cent of defibrinated sheep's blood. Plates were incubated not less than 18 hours before examination. Suspicious looking colonies were examined by means of smears stained by Gram's method, and when Gram negative organisms resembling meningococci were found an agglutination test was made. This was done by fishing suspicious looking colonies and suspending the organisms in 0.5 c.c. of salt solution (0.8% NaCl). Amounts of 0.05 c.c., 0.025 c.c. and 0.01 c.c. of a 1:4 dilution of diagnostic antimeningococcic polyvalent serum were placed respectively in three tubes, and to each was added 0.1 c.c. of the suspension of organisms. A control tube was also prepared.

The tubes were shaken for 2 minutes, incubated at 37° C. for 1 hour, and immediately read. The amounts of serum used for the tests were respectively 0.0125, 0.00625 and 0.0025 c.c. Positive results were reported only when agglutination was obtained in the tube containing the smallest amount of serum (0.0025 c.c.) and the control negative.

The possibility of agglutination by normal horse serum was considered. A series of tests showed that some horse serums agglutinated meningococci in amounts of 0.01 c.c., but not in 0.0025 c.c. Three of the serums tested failed to agglutinate in a 1:10 dilution. Pooled serums behaved as might have been expected from the results with single serums.

We believe our technic has been similar to that used by others. Our aim was to obtain accurate results in as short a time as possible. It was necessary to release contacts negative for meningococci as soon as practicable. Twenty-four hours from taking the culture was as short a time as could be allowed for suitable reports.

From February 6 to July 31, 1929, 2,892 contacts with 619 cases were investigated, or an average of 4.67 contacts per case. For purposes of discussion the time is divided into 3 periods: February 6–March 31, April 1–June 1, and June 2–July 31. During the first period cultures were taken from 709 home contacts with 131 cases; 332 persons, or 46.8 per cent, gave one or more cultures positive for meningococci. During the second period cultures were taken from 1,406 home contacts with 310 cases; 207 persons, or 14.7 per cent, gave one or more cultures positive for meningococci. During the third period cultures were taken from 777 contacts with 178 cases, and 23, or 2.96 per cent, were found positive for meningococci one or more times. The percentage of positive contacts by weeks varied from 0.0 during the weeks ending June 23 and July 31, to 65.6 per cent for the week ending February 17.

The high percentage of carriers found during February, March and the first half of April is in striking contrast to many reports found in the literature dealing with military outbreaks of cerebrospinal fever; but is in agreement with figures given by Ostermann and by Bruns & Hohn, as quoted by Frost,[1] for examination of home contacts. It should be emphasized that we were taking cultures only from persons who had been in rather intimate contact with patients.

Unfortunately, we were unable to obtain cultures from any large number of persons who gave no history of contact with meningitis cases. However, during April, 117 non-contacts were studied and 5, or 4.3 per cent, were positive for meningococci. Of 619 contacts during this same month 146, or 23.6 per cent, gave positive cultures. In July, no carriers were found among 169 non-contacts, while 8 carriers were located among 335 known contacts. Only one culture was made from each non-contact. As will be pointed out below this probably involves some error.

It is obvious that, as warm weather approached, the number of contact carriers diminished. The percentage of positives dropped markedly about 4 weeks before the peak of the epidemic, as indicated by the weekly reports of cases, was reached.

It was necessary to obtain more than one culture from a contact in order not to miss a considerable number of carriers. Of the 332 carriers detected during the period February 6–March 31, 236 gave

cultures positive for meningococci at the first examination; 89 were positive at the second examination after being negative at the first; 6 were positive after two negative cultures; and 1 gave meningococci after three unsuccessful attempts. With only one examination we would have missed nearly 30 per cent of our carriers.

By grouping the carriers according to age and sex, an effort has been made to determine the effect of these factors on the carrier state. Only the figures for the first two periods (February 6–March 31, and April 1–June 1) were used, since the number of carriers in the third period was too small for statistical purposes. Among 2,115 contacts, 1,091 were male and 1,024 female. Of the males 25.6 per cent were carriers (i.e., gave one or more positive cultures), and of females 25.4 per cent. Age appeared to have no influence on the carrier state. For example, 12.4 per cent of contacts were in the 5–9 age group, while 14.8 per cent of carriers were in this group. Fifty-eight and nine tenths per cent of the contacts were 20 years old and above, while 56.8 per cent of the carriers fell in this age group. The percentage of carriers to total contacts in each age group was slightly higher for the 1–4 and 5–9 ages, but the differences were too small to be of real significance.

Crowding is supposed to be a factor in meningitis. Presumably, in a civil population we would expect to find a higher percentage of carriers in crowded rooming houses than in residential districts containing 5 or less persons to a home. The 131 cases investigated between February 6 and March 31 were grouped on the basis of number of contacts per case. In the group with 4 or less contacts per case there were 51 cases and 157 contacts, of whom 64, or 40.7 per cent, were carriers. In the group with 5 to 9 contacts per case there were 71 cases and 446 contacts, of which 211, or 47.2 per cent, were positive. The final group, with 10 or more contacts per case, was composed of 9 cases and 106 contacts, of which 57, or 53.7 per cent, were carriers. These figures indicate a somewhat greater tendency for carriers to be found in the more crowded houses. However, the figures for the second period (April 1–June 1) show just the reverse, being 15.2, 15.2, and 11.9 per cent for the three groups respectively.

The persistence of carriers is a point of some importance. We were able to follow most of our carriers for 2 weeks but no longer, since that time was fixed in our isolation regulations. Again using the three divisions of the 6 months' study—in the first period 32.8 per cent of carriers had not given two consecutive negatives before release, in the second period 25.6 per cent, and in the third period 30.4 per cent had not satisfactorily cleared up. While the advent of warm weather

was coincident with a great decrease in the number of carriers, proportionately the tendency to persist was about the same.

It is necessary to stress the uncertainty of obtaining accurate results in the detection of meningococcic carriers. We have had many experiences which convince us that conclusions from our laboratory data must be drawn with care. Either the carrier state is an intermittent one or our technic is not sufficiently exact—possibly both. Sometimes inconsistent results can be explained, but at other times not. One of our contacts gave the following results for meningococci, —, +, —, —, and accordingly was released. One week later she was sent to the laboratory by her physician because he found that she had been using a gargle during the time the last two negatives* were obtained. The next four examinations gave +, +, —, —. One month later she was still negative. This is by no means an isolated instance.

SUMMARY

This paper gives the results obtained by taking cultures of 2,892 home contacts with 619 cases of epidemic meningitis over a period of 6 months.

The percentage of carriers to contacts varied weekly, from 0 to 65.6 per cent. The highest percentages were found during the winter and early spring months, and the lowest during June and July.

More than one nasopharyngeal culture is needed to detect a considerable number of carriers.

Sex and age play no part in the tendency to become a carrier.

The number of persons in a house has no relation to the percentage of carriers found.

Carriers persist for 2 weeks as frequently in warm as in cold weather, although the actual number of carriers is greatly diminished.

As a result of measures instituted for the control of home contacts with cases of epidemic meningitis, 70 per cent of meningococcic carriers have been isolated until the carrier condition has terminated.

* Negative for meningococci. Other organisms are always present.

NOTE: Assistance has been given in the laboratory work by Catherine O. Wiltsie, Norma H. Broom and Irene Baisley.

Sudden Heart Failure as a Public Health Menace

ALBERT S. HYMAN, M. D., F. A. C. P.

Witkin Foundation for the Study and Prevention of Heart Disease, Beth David Hospital, New York, N. Y.

THE public health aspect of heart disease has been presented with considerable statistical data by many writers during the past decade. Increasing annual morbidity and mortality rates from diseases of the cardiovascular system have been especially demonstrated from such able workers as Cohn,[1] Emerson,[2] Halsey,[3] and Pedley.[4] There can be no doubt that the lay public, as well as the physician, is becoming more and more conscious of the fearful toll exacted by the rheumatic and degenerative diseases of the circulatory system; widespread publicity and organized propaganda for enlightenment have made these facts known to all.

Little, if any, emphasis, however, has been placed upon that phase of the cardiovascular diseases which renders an individual suffering from such a condition a possible menace to the health and happiness of others.

The public health problems concerned with leprosy, smallpox, and typhoid carriers have indicated the health hazards to the community presented by those so afflicted; no less important are the problems concerned with sudden heart failure. Temporary or fleeting attacks of muscular weakness, loss of coördination, or actual unconsciousness, may prove to be a menace not only to the individual himself, but also to all those in his immediate environment. This is especially true when such an individual—in control of powerful mechanical and other appliances which require the entire attention and ability of the operator, drivers of vehicles like automobiles and railroad trains, street car motormen, elevator operators and others in occupations where the lives of many are dependent upon perfect mental and physical functioning—may, as a result of temporary and sudden loss of ability to control their activities, place the lives of others in jeopardy.

Three such cases occurring within the period of a single week recently have served to focus attention upon possible measures to pre-

vent the recurrence of similar tragedies. These cases are presented in some detail in order to demonstrate how varied may be the cardiovascular pathology responsible for the condition.

CASE 1

The first case is that of a man, 54 years old, the driver of an 8-ton automobile truck for 9 years. He was apparently in splendid physical condition, a great strapping fellow, weighing about 230 pounds and 6 feet tall. It was not difficult for him to throw a 150-pound barrel on the truck without assistance.

One day while driving through one of the crowded east side streets, he apparently lost control of the machine, which plunged onto a sidewalk, tearing down a store front. Fortunately only a few bystanders were injured by flying glass. A few minutes after the accident, the driver clambered down from the truck and could offer no explanation of what had happened. He had no difficulty in driving away, and continued with his work the rest of the day.

A few weeks later, and again a month later, similar accidents happened. In the first, the truck tore down a support in a garage, several workmen barely escaping with their lives when the roof crashed. In the other, the truck crashed into several vehicles on the street and many persons were more or less severely injured. In this latter accident, the driver was picked up unconscious and removed to a nearby physician's office.

The doctor noted there were insufficient evidences of trauma to account for the unconsciousness; no signs of fractured skull were found. The pulse was scarcely palpable while the heart sounds were very rapid and weak; the doctor concluded that these findings were associated with shock. In about an hour the patient suddenly resumed consciousness, stood up and insisted on going home. The doctor now noted that his pulse was slow but that the heart sounds were of poor quality, and kindly referred the case to me for cardiovascular study.

The following important findings were made: X-ray examination showed that the heart and aorta were both considerably enlarged; the blood pressure was high, two readings giving systolic 220 and 210 mm. and diastolic 120 and 100 mm. Electrocardiographic examination showed evidences of coronary artery sclerosis with a beginning right bundle branch block. Vital capacity and other tests showed a considerable loss of myocardial reserve. Two days later, while waiting in an examining room the patient complained of feeling weak, and collapsed. Examination at that time revealed a rapid and thready pulse averaging from 130 to 160 per minute. Blood pressure was found to be, systolic 80, diastolic 60 mm. Electrocardiographic studies showed a tachycardia of ill defined origin. The graphic records show the condition so clearly that they are presented to demonstrate his normal rhythm and that occurring during an attack (Figure I). The patient made a quick recovery a few minutes after these tracings were taken and again his blood pressure and pulse rate returned to normal condition. A diagnosis of paroxysmal tachycardia of coronary artery disease origin was made.

The position of a cardiologist in cases such as this is, indeed, perplexing. Inasmuch as the patient has a vascular degenerative disease of the heart which is progressive, and since the attacks are due to sudden circulatory changes, the question of permitting him to resume

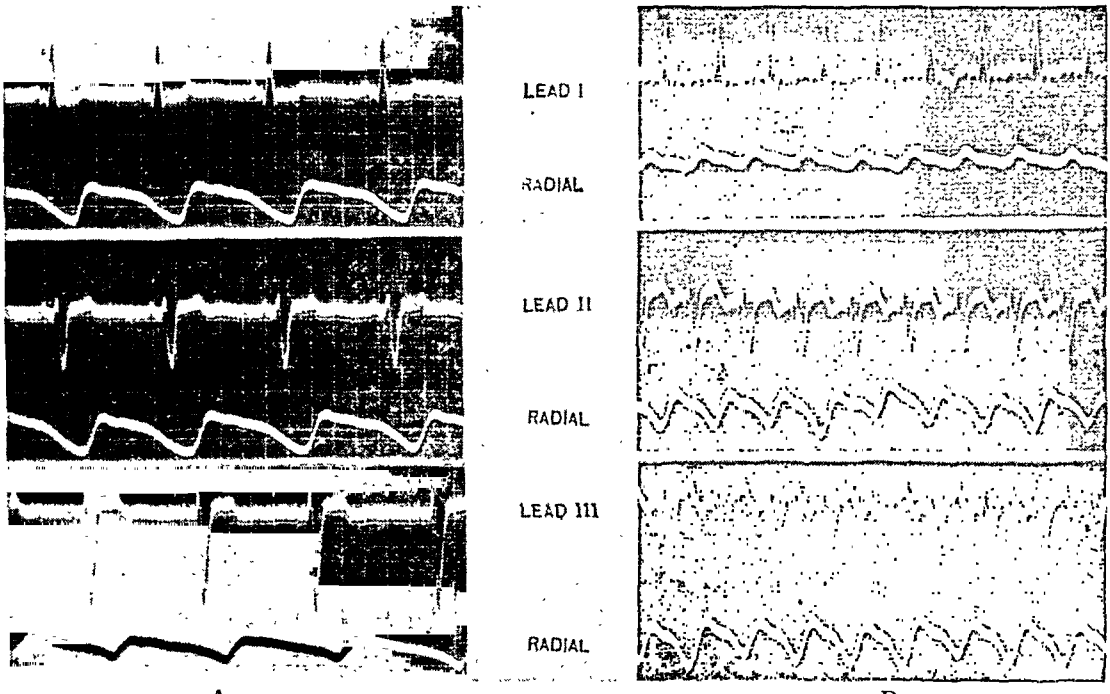

FIGURE I—The upper record in this and in the following figures is the electrocardiographic tracing; the lower is the polygraphic tracing of the radial pulse. Both are photographed simultaneously in order to demonstrate the relation between the electrodynamic phase of the cardiac cycle and the actual mechanical contraction of the left ventricle. The heavy white perpendicular lines represent 0.20 seconds. "A" was taken during the patient's normal rhythm; the ventricular rate is about 60 beats per minute. "B" was taken during an attack; note that the ventricular rate is now varying from 140 to 150 beats per minute. Both records show evidence of coronary artery disease with a marked left axial deviation of the heart.

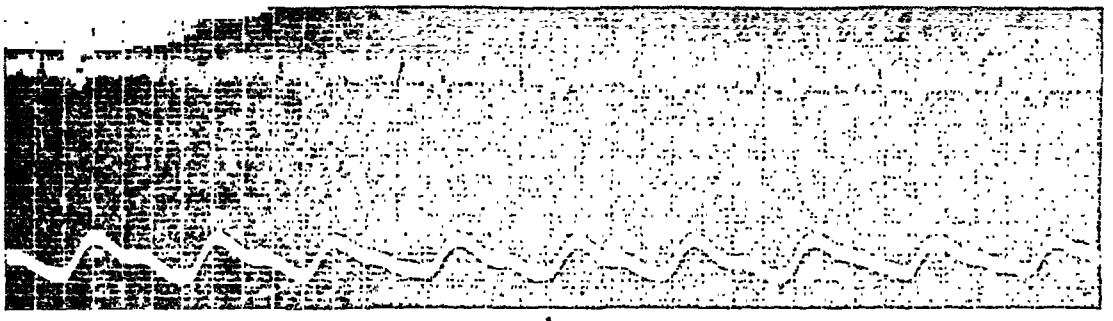
his occupation as a truck driver is one involving a fine sense of professional judgment and duty. From a public health standpoint in its widest definition there is no question that the patient is a menace to the community as a driver of a great truck upon crowded city streets; the hazard to lives and property should he have another attack while crossing a busy thoroughfare is evident. On the other hand, truck driving is this man's sole occupation and his only mode of livelihood. If the attacks do not recur, he is a capable and efficient member of industrial society; he fills a useful place in the community. It is obvious that if the employer should learn the true nature of the matter he would be unwilling to have the man continue in this capacity, for the liability might be too great.

The rôle of the physician under these conditions is not well defined. Vascular degenerative diseases of the heart are not reportable to the health departments of the city or state, as typhoid carriers and cases of leprosy are; yet as hazards to the public health they are no less important. At the same time, the personal responsibility to the patient and his family demands that he be induced *voluntarily* to give up his

employment as a truck driver, not only for his own welfare but for that of others. In the face of refusal to do this the physician is presented with a double-edged problem: duty and faith to the employer and to his patient. I do not pretend to offer a solution. The patient (case No. 1) after a long discussion agreed to take up some other type of work.

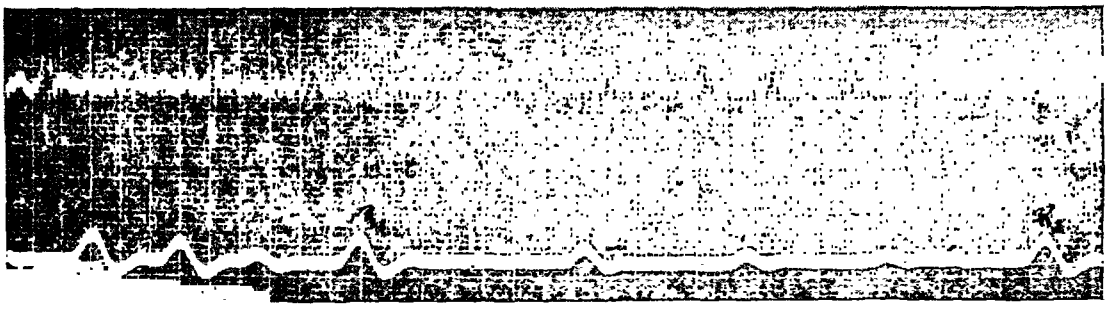
The second case is presented because it is not uncommon and because the public health aspects of the problem are rarely considered, yet the possibilities for harm are great.

CASE 2



A young woman, aged 28, had been employed as an elevator operator for more than 4 years in a large office building in New York City. Her record had been excellent, but one day, while descending, the car suddenly dropped several floors and many passengers were shaken up. Investigation showed no mechanical defects of the elevator. Subsequently, other accidents occurred to the various cars which this young woman was operating. Inspectors, who were watching her, reported that she was extremely careful but was apparently becoming very "nervous" because of the accidents.

One morning she was found unconscious in a car which was located between the 14th and 15th floors. With some difficulty, officials managed to remove her from the car to an adjacent office and a physician was summoned. He noted that she was pulseless; the heart sounds were very loud but very irregular; the rate was very rapid.



Called to see the case in consultation, I made a diagnosis of paroxysmal auricular fibrillation of mitral stenotic origin. Subsequently it was learned that the patient had a long history of rheumatic heart disease and had suffered from mitral stenosis for many years. Cardiovascular examination revealed a rather typical mitral rheumatic heart with low function tests. The graphic records are especially interesting in showing the difference in the circulation during an attack of fibrillation and during normal sinus rhythm (Figure II).

It can be readily noted that the ventricular rate during the attack of fibrillation is so rapid that the left ventricle is incompletely filled, and sometimes there is a contraction when it is entirely empty; this results in only partial or no opening of the aortic valves. From a hemodynamic point of view there develops a very poor peripheral circulation which clinically is manifest, with attacks of syncope or unconsciousness. Under such conditions the brain usually suffers most, and moments of *petit mal* are common; during this period coördination is lost but may be regained a second or two later. Several such attacks were carefully studied; one is recorded in Figure IIB. Note the radial pulse absent for 4.4 seconds.

The cardiologist's standpoint in this case is clear-cut; the results of the cardiovascular study indicate that the patient is suffering from a severe form of heart disease which may render her at any time unfit for the occupation in which she is engaged. The danger to passengers in the elevator, should she suddenly become unconscious, is too obvious to permit of discussion. A periodic health examination, or an ex-

A

B

FIGURE II—"A" shows a normal auriculo-ventricular rhythm with a radial rate of about 72 beats per minute.

"B" shows what happens when fibrillation of the auricles occurs; the ventricular rate now is grossly irregular, varying from 110 to 150 beats per minute. During the rapid phase the aortic valves do not open and from R_1 to R_2 there is a period of over 4 seconds before an effective beat comes through. The peripheral circulation and especially that of the brain may respond with the usual symptoms of acute anemia.

amination at the time she applied for work, should, of course, have been made. Most of the hazards formerly encountered in elevators have been gradually eliminated with the installation of automatic safety devices; the one great hazard still unprovided for is the *individual* operating the car! Too often, jeopardy to life and limb is caused by physically incompetent persons. In this regard it is interesting, though somewhat distressing, to note that only recently in compiling a list of suitable occupations for the "cardiac cripple," a certain welfare organization recommends "the running of passenger elevators as a job not involving too great stress for those thus handicapped. . . ."

How often the lives and welfare of innocent bystanders may be jeopardized is aptly illustrated by case 3, which was referred to me for cardiovascular study.

CASE 3

A man 61 years old, a stationary engineer, was employed by a structural steel corporation to run a powerful hoist used to raise steel beams and girders to the upper floors of a skyscraper in the process of construction. The control of the mechanism required long experience and instantaneous ability to activate the proper levers in response to signal bells, rung by a "guider" or look-out man high up in the structure of the building.

One day, after a series of minor accidents, which were the result, apparently, of some slip in the coöperation between the guider and the engineer, a steel arch, weighing many tons, through some mistake in signals had slipped and crashed through the sidewalk from a considerable height. When the ambulances had completed emergency work, attention was directed for the first time to the engineer. He was found semi-conscious bending over the gears of his machine; a clammy sweat and a peculiar pallor caused the ambulance surgeon to insist that he go to the hospital. After a brief stay, he returned to his home; the following day he had another attack which rendered him partially unconscious. The family physician noted that the patient's pulse was very slow, at times 20 to 30 beats per minute, with poor heart sounds.

A few days later after another attack, I made a presumptive diagnosis of complete heart block or auriculo-ventricular dissociation. Cardiovascular studies revealed a rather unusual phenomenon which is very beautifully visualized by the accompanying electrocardiographic and polygraphic tracings (Figure III). The

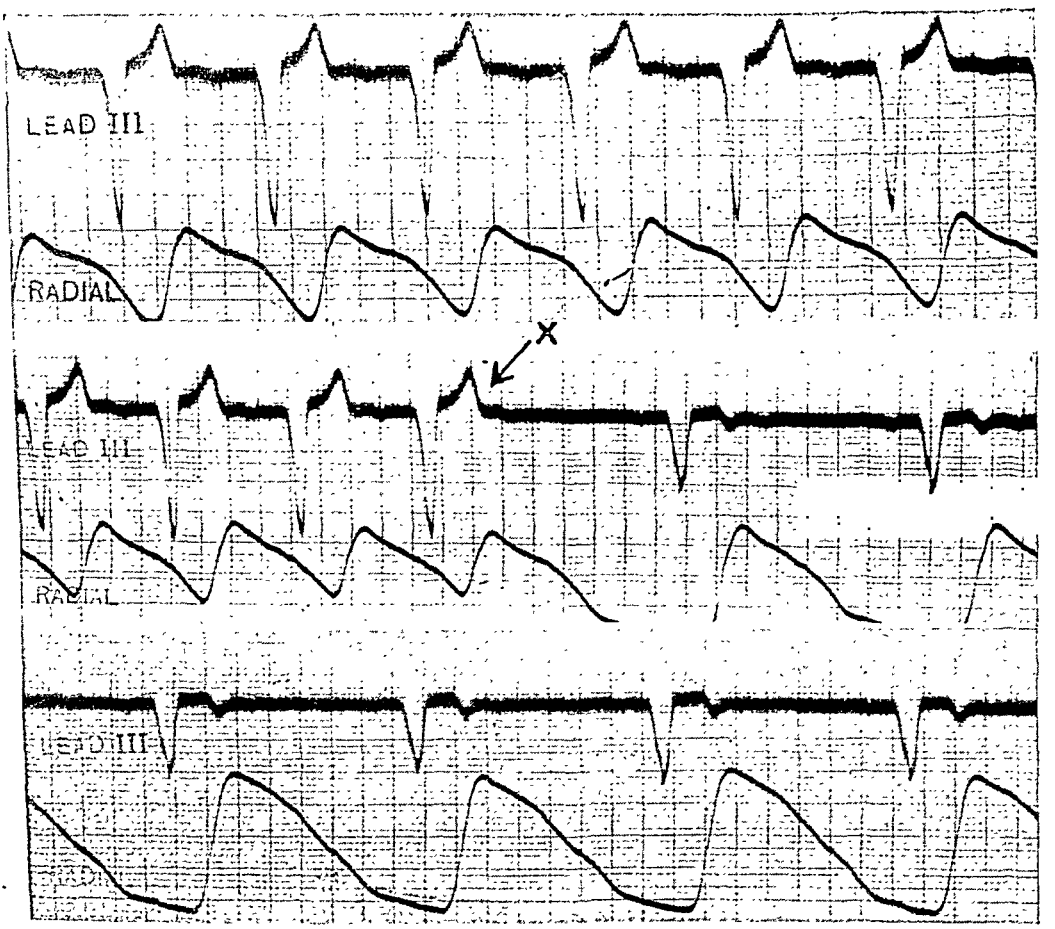


FIGURE III—The three records are continuous from above downward. The first shows a normal sinus rhythm; there is present in other leads evidence of serious myocardial damage. The radial rate averages 74 beats per minute. The second record shows the sudden transition from sinus rhythm to complete dissociation of auricular and ventricular rhythms; the radial rate drops to 34 beats per minute.

patient had an attack during the examination. It will be noted that the normal sinus rhythm at the point marked "X" suddenly stops and there develops a slow, less regular rate of about 38 beats per minute, with independent auricular and ventricular rhythms. The condition from a cardiologic point of view approaches the Stokes-Adams syndrome, but in this case the symptomatic response to the sudden change of rhythm is out of proportion to the actual change in the peripheral circulation.

The sudden change in the rhythm is responsible for the period of unconsciousness or loss of coördination ability. Under ordinary conditions of life such attacks of weakness may not be of great significance, but in a position involving tremendous physical and mental responsibilities they may assume tremendous importance.

In presenting these three cases, the public health aspect has been emphasized, as attention is usually focused upon the individual himself. Treatment and prognosis have no place here, but the problem of preventing such accidents may well invite our consideration.

Accident prevention in so far as it is dependent upon the integrity of the human mechanism must receive its greatest support from the facts and information discovered by personal examination of the individual; this is especially true where an individual is engaged in an occupation where great hazard to others may be the result. In this group may be placed the condition known, for want of a better name, as "sudden heart failure." But the name "sudden heart failure" is in itself paradoxical; the condition nearly always occurs in persons *who have had heart disease for some time.* It is *sudden* only because there is an acute change or re-arrangement of the circulation. If this be true, then the attack might be anticipated, and had public health measures kept pace with the knowledge of cardiovascular diseases, such accidents might be entirely avoidable!

The solution of the problem, as I see it, is not difficult; it means periodic health examination propaganda carried to legislative bodies. Individuals employed or seeking employment in the occupations discussed above would be required to submit to an examination to prove their physical ability to cope with the demands of their work without danger to themselves or others. Sufferers from heart disease should not be required to undergo the stress and effort attendant upon occupations which might prove to be hazardous. They and the community as well should have the same protection as that afforded where there is disturbance of vision. The State of New York, for example, demands that all applicants for automobile drivers' licenses shall be able to see certain standards without glasses. What avails it, therefore, to prevent the blind from driving when a man with serious heart disease may fall dead at the wheel of a large automobile truck? The danger to the bystander appears to be equally great in either case.

Great public health benefit will accrue from the enforcement of examinations of those employed in the hazardous and semi-hazardous occupations. Heart disease, when it is diagnosed, must be considered one of the great causes of preventable accidents, and to those interested in the problem an opportunity for splendid and far reaching public health service is offered.

New Legislation to Protect Mothers in Italy

AN Italian decree law of May 13, 1929, prohibits the employment of women during the last 4 weeks of pregnancy and the first 4 weeks after childbirth. The woman's position must be reserved for her during this time and also during an additional period not to exceed 3 months if she is unable to return to work at the end of the shorter period. A confinement benefit of 150 lire (a little less than $8 at the current rate of exchange) is to be paid to the women and also a weekly sum equal to the unemployment benefit is to be paid to those who are subject to unemployment insurance, as the majority of manual and clerical workers are. Two special rest periods of 1 hour each must be given daily to nursing mothers until their children are 1 year old.

The law includes manual and clerical workers in all industrial and commercial establishments, and may be extended by royal decree to women employed in heavy agricultural work. Fines are provided for violations of the law (*Gazzetta Ufficiale*, Rome, June 6, 1929, p. 2538).

This decree is intended to supplement previously enacted measures for the protection of employed mothers. For instance, the labor law of 1907 prohibited the employment of women in industry for 4 weeks after childbirth; the present decree adds to this period 4 weeks before childbirth, and extends the provision to all manual and clerical workers.

The maternity insurance law, as amended in 1923, provided a maternity benefit of 100 lire; this amount is raised to 150 lire by the new decree, and is to be paid not only to industrial workers but also to workers in commercial establishments. Finally, there is provided for the first time a weekly cash benefit to be paid to women absent from work on account of childbirth.

Endemic Goiter and Its Relation to Iodine Content of Food *

JAMES A. HAYNE, M. D., FELLOW A. P. H. A.

State Health Officer, Columbia, S. C.

GOITER has been described since ancient times; its treatment by food supplies containing iodine was practiced in China thousands of years ago; and it is said that burnt sponges which contained iodine were used by the Phoenicians for the same purpose.

I think it is well to establish in our minds just what we mean by goiter. In looking over the surveys which have been made in various countries, we find that a simple palpable enlargement of the thyroid gland exists in perfect health, especially in females where the enlargement of the gland is not uncommon at the catamenial periods and also during pregnancy. When the thyroid gland enlarges to the extent that it is visible, conspicuous, unsightly and may produce pressure upon the windpipe and other important structures of the neck, it may be termed goiter.

Goiter is one of the best examples we have of an endemic disease. It occurs all over the world but is much more prevalent in certain localities, such as large valleys, mountainous regions, and elevated plains, where also the condition known as cretinism is found. Many theories have been advanced as to its cause, but the accepted idea at present is that it is due to a deficiency of iodine in the food or water supply of the particular locality in which goiter is endemic. We are speaking entirely of simple, not exophthalmic goiter, Graves' disease, or Von Basedow's disease. Here we have a pathological condition with extremely dangerous symptoms.

Baumann, in 1895, discovered that the human thyroid contained an organic compound of iodine. Kendall, in 1914, isolated from the thyroid gland of a sheep a substance which he called thyroxin, which contained 65 per cent of iodine. This was synthetically produced in the laboratory by Harrington. The function of the thyroid gland is to produce this thyroxin. When it fails to produce it in sufficient

* Read before the Forty-fourth Annual Conference of State and Provincial Health Authorities of North America, Washington, D. C., May 31–June 1, 1929.

quantities we have the condition known as hypothyroidism; the cells of the gland then proliferate and we have enlargement of the thyroid gland, or goiter.

We have a goiter map prepared by Dr. Olesen of the U. S. Public Health Service which shows the distribution of goiter in the United States, from the results of the examination of drafted men in the recent war. As it relates only to men it is very inaccurate. Proper surveys to determine the amount of goiter in the various states of the United States have been made in but few states. Surveys made in Minnesota, Montana, Michigan, and recently South Carolina, and some surveys made in Tennessee, some in Ohio, and possibly in some other states, furnish all the data we have. In looking over the literature of the U. S. Public Health Service in regard to the occurrence of goiter in the United States we find that most of the statements are based upon guesses made by state health officers for their respective states. I wish to urge that a complete survey be made so that we may know how much goiter we have and where it exists. Roughly speaking, the goiter area consists of an area of the United States containing about 30 million people. In this area are the states of Illinois, Wisconsin, Ohio, Iowa, Indiana, Nebraska, Michigan, the two Dakotas and Montana; and on the west coast, Oregon, Washington and California. Surveys of high school girls in Michigan and Minnesota show that as high as 70 per cent show definite thyroid enlargement.

Studies of the water supplies of these areas show a great deficiency in the amount of iodine present, and certain methods have been adopted to furnish it, such as the use of table salt containing iodine. This salt has been widely put upon the market, and there is great difference of opinion as to the results obtained. It was suggested by Dr. Turrentine, of the U. S. Department of Agriculture, that possibly food would contain iodine in natural combination which would be less rapidly eliminated from the body than the inorganic iodine, and would produce better results in the prevention and treatment of goiter. This was reasoned out from the analogy in the treatment of pernicious anemia.

It was found that when people who suffered from pernicious anemia were treated with liver, the iron and copper contained in the liver relieved the condition, whereas iron and copper administered as inorganic salts did not have any such effect. Beard and Myers, at Western Reserve University, treated rats with liver and found that they could relieve the pernicious anemia, whereas they could not relieve it by administering copper, manganese and iron in inorganic salts.

TABLE I

GOITER SURVEY OF SOUTH CAROLINA

County	*No. Examined*	*Normal*	*Enlarged*	*Percentage Goitrous* *
Beaufort	230	224	6	3

Charleston	3,168	3,039	129	5
Dorchester	834	828	6	1
Georgetown	408	406	2	1
Horry	729	720	9	1
Total	5,684	5,529	155	3
Darlington	819	807	12	1
Dillon	1,622	1,499	123	8
Marion	392	384	8	2
Orangeburg	1,301	1,269	32	3
Total	4,134	3,949	185	5
Aiken	1,566	1,555	11	1
Fairfield	515	502	13	3
Richland	278	272	6	1
Total	2,359	2,329	30	2
Anderson	573	564	9	2
Cherokee	564	543	21	4
Greenwood	684	667	17	3
Newberry	700	685	15	2
Greenville	1,433	1,425	8	1
Oconee	1,008	994	14	2
Spartanburg	461	455	6	1
Total	2,902	2,874	28	1
Grand Total	17,600	17,140	460	3.8

* Percentages given to nearest whole number.

It was found by Robsheit, Robbins and others that the liver contained 58.5 p.p.m. of iron, 75.9 of arsenic, 145 of copper, 49 of manganese, and 30.3 of calcium; that the kidney contained 108.9 p.p.m. of iron, 142 of arsenic, 101 of copper, 106 of calcium and 154 of manganese. It was also found that dried apricots contain 48.4 p.p.m. of iron, 181.3 of arsenic, 144.5 of copper, 140 of calcium, and 140.1 of manganese. Accidentally in feeding rats with dried apricots they were obtaining practically the same results as from the use of liver.

Reasoning from the above it was thought that perhaps the iodine contained in vegetables would be of great benefit in the treatment of goiter, and the experiments of Beard and Myers with rats seem to confirm this theory.

Upon the basis of the foregoing it was decided to have an analysis made of the vegetables and fruits of South Carolina. A number of

tables are presented showing the large content of iodine in the fruits and vegetables of South Carolina.

Results of a recent survey of South Carolina for goiter are given in Table I.

The amount of iodine in the daily ration necessary in order to maintain iodine balance is unknown. We know of but one careful experiment—that of Dr. von Fellenberg of Switzerland, who was able to maintain iodine equilibrium over a period of 4 weeks in a man on a diet which contained 0.0143 mg. per day (equivalent to 5.22 mg. per year). It is interesting to calculate the weight in ounces of some fresh vegetables from South Carolina which will yield this amount of iodine (see Table II).

TABLE II

IODINE IN SOUTH CAROLINA VEGETABLES

	Leafy Vegetables	
Cabbage	Average of 8 samples	7 ounces
Lettuce	" " 9 "	8 "
Spinach	" " 14 "	7 "
Turnip Tops	" " 5 "	10 "
	Potatoes	
Potatoes	Average of 76 samples	11 ounces
Sweet Potatoes	" " 70 "	16 "
	Roots	
Beets	Average of 4 samples	24 ounces
Carrots	" " 8 "	21 "
Turnips	" " 12 "	23 "
Asparagus	" " 22 "	27 "

On this basis a diet containing 4 oz. of green vegetable, 8 oz. of potatoes and 4 oz. of root vegetable would yield 0.021 mg. of iodine per day, which is about 150 per cent of the value of von Fellenberg. Since this quantity can be, and frequently is, eaten at a single meal, it is felt that these vegetables are adequate for goiter prevention when eaten regularly.

The survey in South Carolina shows that we have a small amount of goiter, and one naturally asks why, if we have so much iodine in food, we have goiter at all. This is easily answered when we consider that the people do not eat South Carolina vegetables. A study of the situation seems to show that vegetables used in the cities of South Carolina come largely from other states. This is especially true of canned vegetables, as there are no large canneries in the state. It is also true that a great many people do not eat vegetables. In a study of pellagra it was found that although foods containing sufficient pellagra preventive were on the tables of many people in South Carolina, they were not eaten by all the family.

TABLE III

IODINE CONTENT OF SOME SOUTH CAROLINA VEGETABLES, COMPARED WITH RESULTS PUBLISHED BY MCCLENDON FOR VEGETABLES PRODUCED IN CALIFORNIA AND OREGON

	South Carolina Analyses by Remington	California Analyses by McClendon	Oregon Analyses by McClendon
	p.p.b.	p.p.b.	p.p.b.
String beans	429	—	29.0
Beets	233	8 0	—
Carrots	135	8.5	2.3
Lettuce	754	—	—
Peas	197 (ripe)	8.4 (green)	—
Potatoes	517	—	—
Spinach	424	26.0	19.5
Soup vegetables	—	—	13.5
Squash (summer)	1,018	—	—
Sweet potatoes	135	—	—
Tomatoes	273	17.5	—
Asparagus	145	12.0	—
Cabbage	504	—	—
Cucumbers	523	—	—
Egg plant	338	—	—

Results are in parts per billion of iodine in the dried vegetables.

We are just beginning to appreciate the part that food plays in the prevention of disease and the conservation of health. When the germ theory was evolved it was thought that the question of disease prevention was settled, but as the years have elapsed we have found that there are many things that have to be added in order to explain correctly the transmission of communicable diseases, and also that there are many diseases which are not caused by germs but by faulty food habits.

The laboratory which we have established in Charleston in connection with the South Carolina Medical College is making analyses of all vegetables and fruits grown in South Carolina, and these are being compared with analyses made in other states. Unfortunately, this work has been carried on only in a very few states and we have very few data for comparison. It is urged that each state health officer inform himself as to the methods used both by Dr. McClendon of the University of Minnesota, and Dr. Roe E. Remington, our chemist in Charleston, and that proper analyses be made of the fruits and vegetables of other states so that we may have a basis of comparison.

One outstanding discovery has been made through our analyses which upsets completely a theory which has been held in regard to where iodine would be found in the largest quantities. It has been held for a long time that the salt spray, or the sea spray, was the source of iodine. Tables V and VIII seem to disprove this theory, as we find the iodine content of our fruits and vegetables higher in the

mountainous regions of the state, 250 miles from the coast, than in areas 30 or 40 miles from the coast. Of course, right along the coast there is more iodine in the vegetables. Granite and other rocks which are found in the Appalachian Mountains contain iodine, and

the disintegration of these rocks has increased the amount of iodine found in the soils in the upper part of the state.

Iodine is a natural plant food and where it is contained in large quantities in the soil plants grow extremely well. It seems that in the metabolism of the plant iodine is the natural constituent, as it is in the metabolism of man. Iodine is contained in fish, oysters, and other sea life, but these are not staple articles of diet in the state; in fact, they are not used as such even on the coast. McClendon and others have examined a large number of samples of surface water from different parts of the United States, but there is practically no place in the country where drinking water contains enough iodine to provide for the needs of the body. The examination of foods in Maine and Connecticut revealed that there is more iodine in these than in corresponding products in Wisconsin, Minnesota and Oregon, and there is more goiter in Wisconsin, Minnesota and Oregon.

We felt that the work done under the auspices of the South Carolina Food Research Commission—composed of Dr. William Weston, Chairman, the President of the State University, the President of the State Medical College, the President of the State Agricultural College (Clemson), the State Health Officer, and Dr. R. R. Walker—was of such importance and brought out so many new facts in regard to the iodine content of foods, that it should be called to the attention of the Conference of State and Provincial Health Authorities of North America, with a view that they might make an investigation and study of these facts, and provide that such food analyses be made in their own states. We know that South Carolina fruits and vegetables contain sufficient iodine for nutritional purposes, and if people will eat South Carolina fruits and vegetables they may reasonably expect not to have goiter.

Industrial Cleanliness and the Courts

JAMES A. TOBEY, LL. B., DR. P. H., FELLOW A. P. H. A.

The Borden Company, New York, N. Y.

LAWS requiring adequate washing facilities to be provided for the employees in various industries are now in force in one-half of the United States. Most of this legislation refers only to special conditions, such as those in coal mines, lead works, or foundries, but some of it applies to all factories and mercantile establishments. Where a law is limited in its application, there may be raised against it constitutional questions which can be decided only by the courts in actions brought before them.

The constitutionality of state washroom laws has been adjudicated by courts of last resort on 8 occasions, including decisions by the Supreme Court of the United States and the highest tribunals of 5 states. In only 1 state is such a law now held unconstitutional, and in that case only because the method of securing establishment of a washroom in a plant is held to be at variance with a special provision of the state constitution. In all other instances the legal principle seems well established to the effect that it is a valid exercise of the police power for the state to require owners or operators of certain industries, such as coal mines, to provide washrooms for their employees, and, furthermore, that the statute may require that such washing facilities be furnished on the demand of a specified number of the employees.

The first litigation on this subject arose in Illinois as a consequence of an act of 1903 (Hurd's Rev. St. 1903, c. 93, No. 37) which required owners of a coal mine to provide and maintain a washroom at a convenient place at the top of the mine. A mine owner was convicted in a lower court for violation of the act and appealed to the Supreme Court of Illinois, which handed down its opinion in 1906.[1] It was insisted on behalf of the defendant that the statute was unconstitutional and the court decided in this case that the law placed upon mine owners a burden not borne by other employers of labor and discriminated in favor of mining employees against laborers engaged in other occupations. For these reasons the act was held invalid as special legislation and as an improper exercise of the police power. Later decisions have, however, changed this principle.

A law of broader scope was passed by the Illinois Legislature in

1913 (Hurd's Stat. 1913, c. 48, No. 184). This act required the maintenance of a sanitary washroom at a convenient place by every owner and operator of a coal mine, steel mill, foundry, machine shop, or other business in which employees become covered with grease, smoke, dust, grime, and perspiration to such an extent that to remain in such a condition after leaving work without washing and cleansing their bodies and changing their clothing would endanger their health or make their condition offensive to the public.

In the litigation which immediately arose—incidentally from the same county as before—the Supreme Court held that this law was valid,[2] stating:

> The purpose of the law is to promote the health and welfare of employees in certain lines of business where conditions are such that every facility should be afforded for cleanliness, and to provide for the comfort and welfare of those with whom such employees come in contact after leaving their place of employment.

This law was held good under the police power of the state, especially since the legislature in enacting the later statute undoubtedly had in mind the previous court decision.

This same law was, however, construed in an extraordinary manner by the same court in a decision delivered a few years later.[3] A railway company was convicted of failure to comply with this statute and the court held that a roundhouse where 60 men were employed did not come within the purview of the law. This, of course, was a question of fact and it was ruled that "the evidence did not bring the roundhouse and the machine shop within the terms of the statute." The sanitary conditions which usually prevail at roundhouses would hardly seem to justify the result.

At about the same time that the Illinois statute of 1913 was sustained, an even more drastic law in Indiana was pronounced valid. This particular act required the owner of a mine to provide washing facilities when 20 or more of the employees petitioned for the installation of such facilities. The Supreme Court of Indiana held that this act was constitutional, saying:

> The provision of the law is a salutary one and is no more unreasonable than the provision of the law which requires the mines be guarded, lighted and ventilated. This act has to do with the comfort, health and care of the employees of mines, and is within the legislative discretion.[4]

The mine owners were not satisfied with this decision, and appealed to the Supreme Court of the United States, on the ground that their rights had been infringed under the Constitution of the United States. The highest court of the land denied this contention and sus-

tained the constitutionality of the state law with respect to its operation under the national constitution, holding that the act did not deny equal protection of the laws.[5] In the course of its opinion, this court stated:

> Having the power in the interest of the public health to regulate the conditions upon which coal mining may be conducted, it cannot be limited by moments of time and differences of situation.

In the same year that this decision of the Supreme Court of the United States was written, the Supreme Court of Kansas upheld a law of 1911 of that state, which required owners of coal mines to furnish washrooms.[6] As in the early case in Illinois, it was asserted that the law was discriminatory, in that it did not place a similar burden on the operators of other mines. The court held, nevertheless, that this contention was not correct as a matter of law. It was the province of the legislature to determine the necessity for the law and the subject came properly within the police power of the state. The Kansas court relied in part on the McLean v. Arkansas and Booth v. State decisions cited above. (See footnotes 5 and 4, respectively.)

The one case which has gone contrary to these decisions is a Kentucky one, decided in 1922.[7] Here there was a state law similar to that in Illinois in that it applied to various industries where employees were covered with grease, smoke, dust, grime and perspiration, and it was also similar to that of Indiana in the provision that a washroom must be erected when 30 per cent of the employees so decide and notify the owner.

In an exhaustive opinion the Court of Appeals of Kentucky reaches the conclusion that the law in question is inconsistent with a section of the Kentucky constitution, which prohibits the enactment of a law to take effect upon the approval of any other authority than the General Assembly. Certain subjects are exempt from this provision, but the regulation of coal mines is not among them, nor is there any provision for such regulation in any other section of the state constitution. Although the Indiana constitution has a somewhat similar provision and the washroom act of that state was upheld under it, the Kentucky court did not feel that it could depart from its consistent attitude in holding that the constitution of its own state was more stringent in this regard.

The most recent case on this subject was decided by the Supreme Court of Tennessee on December 8, 1928.[8] In this decision a statute of 1921 requiring that wash-houses be provided at coal mines employing 50 or more persons was sustained as valid and constitutional. The court held that this legislation was a proper exercise of the police

power and that it was entirely proper for the legislature to decide to legislate in this manner after considering all aspects of the problem. The law, applying only to coal mines of a certain size and over, was held not to be class legislation, because—

> Legislation designed to protect the health of coal miners cannot be said to be founded upon an arbitrary classification, because it is not extended to other industries, in which the legislature may have found that working conditions were dissimilar.

While on this subject of cleanliness, one other court decision should be mentioned. That was a case decided in 1919 by the Supreme Court of Appeals of Virginia, which inferentially sustained an act to prohibit the use of roller towels in public lavatories, but held that a lavatory in an office building owned by a private individual is not a public lavatory and that the act does not apply in such instances.[9]

The great weight of legal authority, as shown by this brief review of the pertinent court decisions on cleanliness in industry, is to the effect that a state is acting properly within the scope of its police power in passing legislation requiring industries generally, or certain special industries where conditions warrant, to install adequate washing facilities for the health and comfort of their employees. Such legislation is not, as a general proposition, invalid because it makes the establishment of washing facilities contingent upon a petition from a certain number of the employees, though this requirement has been held in one instance to be inconsistent with a state constitution.

Voluntary Agencies' Activities in a City Health Education Program*

BLEECKER MARQUETTE, FELLOW A. P. H. A.

Executive Secretary, Cincinnati Public Health Federation, Cincinnati, O.

THE general guiding principle as to the part voluntary agencies should play in the health education program is, generally speaking, the same as that which should guide their general program of work in relation to the community's health program. Governmental agencies have the right of way in both cases.

We may safely assume that it is the obligation of the city health department to do two things in addition to whatever other activities it may undertake. One is to bend its efforts constantly to keep the public acquainted with the functions, purpose and needs of the department; and the other is to keep the public informed as to the health conditions existing in the community as revealed by vital statistics available through the city health department. How much the official department may do beyond that depends upon the zeal and interest of the director, his understanding of the importance of educational work, and his facility or that of a staff member in the art of telling his story to the community, particularly regarding the question of the funds available.

How much the private health organizations should undertake to do will therefore be dependent upon the program of the official department. Competition, above all, is to be avoided. For the sake of harmony and progress the private organization should withdraw in favor of the official department whenever there is a conflict.

The great development of volunteer health activities in recent years, in the fields of tuberculosis, nursing, child hygiene, dental health, housing, cancer, heart disease, social hygiene, mental health, and work for the blind and the deaf, has resulted in most communities in a decidedly disjointed method of health education. The emphasis given to one or another problem is great or little depending upon the vigor, power, and funds of the organization interested in that particular field. Some fields may be practically ignored. Publicity efforts often over-

* Read before the Public Health Education Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

lap and interfere with each other. One of the first jobs of private health organizations is, therefore, to coördinate their publicity and educational programs. This has been done in but few communities. Nevertheless, it is one of the developments that lie ahead and must be attained before the volunteer agencies will find their proper place in the health education scheme and produce results accordingly.

Dr. Louis I. Dublin tells us, and his judgment is confirmed by others, that life expectancy can be increased another ten years if we can apply all of the public health knowledge already available to us, but that to do the job with the highest degree of efficiency the public health department needs a per capita appropriation of $2.50 annually. No health department in the United States has attained such a goal. It seems reasonable to assume that it will be many years before it can be attained for the majority. Whether we consider Dr. Dublin's goal attainable or not, there will be general agreement that far larger appropriations are needed than are now available. Here alone is a task that may well provide a major objective for health organizations for some years to come. It should be one of their main objectives.

Voluntary agencies must interpret their own work and their own problem to the public. Their effectiveness and their financial support will depend to a considerable degree upon their success in this direction. It has usually been true in the past that new pieces of work have to be launched and carried on for a considerable period by volunteer groups. This is true in some communities more than in others, depending to some extent upon the initiative and ingenuity of the health officer, but more upon the relative difficulty of securing funds for official health departments.

In the field of tuberculosis, while most of the actual services are being, and should be, taken over by official departments, a large portion of the task of educating the public to a knowledge of the cause, prevention and cure of the disease, and the operation of summer camps; stimulating reporting by physicians; working along with city officials for adequate sanatoriums and a high grade of service rendered by them in improving the social service and relief programs for the tuberculous; taking charge of industrial placement and similar activities; will fall to the lot of private organizations. In those communities in which the official department has advanced to the point where it has the funds and the staff to carry most of these functions, every encouragement should be given the official department to do it, leaving to the private organizations, perhaps primarily, the task of supplementing the education program.

Not many health departments are equipped to carry on programs

in cancer control or in the prevention and relief of heart disease. So long as these activities are new and not sufficiently demonstrated to make it easy for the health department to undertake them, or where the department cannot get the needed funds, the work should be initiated and carried on by private organizations. A vital part of the task is, of course, education.

There is considerable question as to whether the job of bedside nursing will for many years be considered a part of the responsibility of the official agency. There is no group in the community with greater opportunity to teach the fundamentals of public health in a quiet, practical and effective way than the visiting nurse, for there is no time when information about health "sinks in" more effectively than during illness in the home. Many visiting nurse associations have realized not fully their great opportunity in this field. It remains one of the developments to be fulfilled in the future.

The growth of medical and health service in industry has not been so rapid as many of us have hoped. The average captain of industry seems to be impressed with the fact that he can best limit himself to the job in hand, and steps over only grudgingly and reluctantly into such a field as health protection for his employees. Health education in industry, with the encouragement of the periodic examination of the workers, remains one of the jobs that we have scarcely started. While industrial hygiene is within the province of the official department that is interested and able to undertake it, yet in all probability it will remain for volunteer organizations to take the lead for some time to come. Education will be an important factor.

The city health department is obligated to direct the attack on venereal disease, though at present privately conducted clinics will have to carry on. Law enforcement measures cannot well be assigned to agencies that have not the authority of law. When it comes to the question of teaching sex hygiene, however, it is the volunteer groups that will have to assume the burden. They need also to supplement the efforts of public officials in teaching the facts about these diseases and securing funds for providing adequate service.

It does not often happen that a public official will build up a vigorous program of housing improvement, although he must enforce such laws as may be enacted. Private citizens can stimulate public interest, formulate modern housing and zoning legislation and help to get it enacted, encourage the construction of good homes, teach tenants, and secure public support for vigorous enforcement of the law. It would be difficult to find a city that is doing a good housing job without the educational power of a private agency.

Public health workers interest themselves but little in the field of mental hygiene. They consider to be outside their province such matters as facilities for the care of the insane, the problem of the feebleminded, and that whole broader field of mental hygiene that has to do with the prevention of the minor mental and nervous disorders which cause such a large degree of unhappiness and inefficiency. For the most part it is a task falling to the lot of private agencies, boards of education, or departments of public welfare. There are few fields in which there are more misconceptions and less real understanding.

If communities are to be provided with the right kind of clinic facilities, fitted to the need, properly integrated, conducted in such a way as to enlist rather than to disparage the interest and sympathy of practicing physicians, it is private groups who are most likely to do it. Not that it is a job that cannot be done by a department of health, but the many other tasks devolving upon such departments naturally relegate problems of this kind to the background and, moreover, many directors of city health departments feel that clinic service falls within the scope of curative medicine and is not a function with which the public department should concern itself. There is a distinct educational job to be done here in interpreting to the public the purposes and needs of clinic service. Just as the visiting nurse has an unparalleled opportunity to get over some of the facts about health when she makes her bedside visit, so too there is a great chance to do such a teaching job in clinics.

Similarly in the field of hospital care, the health officer does not usually consider it his responsibility to see that the facilities meet the community's needs, except for communicable diseases. This he considers, and quite rightly so, falls within the sphere of curative medicine. Nevertheless, hospital care is important, and it is a part of the health program that needs particular attention, study and interpretation to the public. There is a tendency in many sections of the country toward over-expansion of facilities for the care of the acute sick. Private health organizations have a responsibility for analyzing the hospital situation in the community and making the facts known to the public in order that the most urgent need will be given priority.

Physicians, nurses, social workers, and the public should realize that provision for convalescent care has been sadly neglected. The public and the government authorities need to be informed that the primary causes of death are undergoing a decided change and that with the lengthening of life more and more people are afflicted with chronic diseases. Practically every community is woefully lacking in

hospital accommodations for the chronic sick. We need to find a way to provide hospital beds at prices within the means of working people. All this means more education and better understanding of our problem.

This matter of the mounting cost of medical care is a pressing problem that demands the attention of private health organizations. Dr. Olin West of the American Medical Association has called it "the one great outstanding problem before the medical profession today." From all cities we are confronted with facts showing that people in moderate circumstances are being asked to pay for care in time of sickness, prices that are completely beyond their reach. The result is a growing social problem, increasing bitterness on the part of people thus charged, and a serious conflict between the medical practitioners who view with alarm the increase in free clinic service, and public health workers who can see no other way under the present circumstances of providing medical care for those of limited means. The income of the average practicing physician is low, in many cases not sufficient to repay the high cost of his education. There are obviously two sides to the problem, and it is a problem that requires most serious consideration. Private health organizations have an obligation to coöperate with the national committee now engaged in the study of this situation, and, if a practical solution is found, to help to educate the public to the findings and in carrying out the recommendations.

The conflict between physicians and public health and social workers is disturbing. It is certainly in part due to the fact that we have not used the proper methods in interesting physicians in public health work, nor in interpreting our work to them. Public departments and private organizations share the responsibility alike for doing a better job in this respect. There are many ways in which private organizations can do much along this line, and these opportunities must not be neglected.

The extent to which the general public are misinformed on some of the simplest facts about health is a challenge to health agencies, public and private. Obviously, our combined efforts have been far short of success in face of the fact that $200,000,000 worth of patent medicines are sold every year in this country, and that many more millions are spent in fees to fake practitioners who constantly hoodwink the public. It is not the amount of money wasted that concerns us, but the danger to the diseased patients who place their confidence in fakes and then go to the ethical physician when it is too late. No need to worry about duplication or overlapping of effort in

our fight against this colossal ignorance. Let us all attack this job with every force at our disposal. The outstanding objective of health education is a better understanding by the lay public of facts disclosed by scientific medicine, and dissipation of the countless superstitions that now abound.

In a general way, it should be the job of the private health agencies, after having coördinated their own efforts, to study the public health needs of the community as a whole, to endeavor to make an intelligent interpretation of the facts to the public, and to build up a sound program of health work adequate to meet the whole need of the community.

Health education has made distinct progress. People understand the purpose of health departments better; many of the old fallacies and superstitions on health matters have been dissipated; and the laity in general are much better informed upon the rules of health than they were in the past. The job that lies ahead, however, is almost boundless. So long as practically all departments of health are receiving sadly inadequate funds; so long as almost no community in the country has a really complete and satisfactory health program; so long as in one large city there are 59 different types of medical cures and cults; so long as $200,000,000 worth of proprietary medicines are sold annually; so long as we have constantly to fight against anti-vivisectionists and anti-vaccinationists; there is a job big enough to tax all of the resources of both public and private health agencies. The most inexcusable thing that can happen is for these groups in any given community to fail to work out their programs in such a way as to accomplish the best results with the least expenditure and the least friction.

Accidents Kill More than War

MORE people die annually from accidents in Illinois than were killed in action in any battle of the Civil War.

During the World War 36,931 United States soldiers were killed in action. During the last 7 years accidents have resulted in 38,532 deaths in Illinois.

Only heart disease, cancer and nephritis among all the diseases cause greater mortality than do accidents. In some years the mortality from pneumonia is greater than that from accidents but the average is less.

These comparisons suggest the enormity of the accident problem. Since accidents occur because people are out of tune with their environment it appears that there must be more than a modicum of truth in the assertion that man is his own worst enemy.—*Illinois Health Messenger*, 1, 17 (Sept. 1), 1929.

Educational Aspects of Dairy and Milk Inspection*

C. L. ROADHOUSE

Professor of Dairy Industry, University of California, Davis, Calif.

THERE are many instances where dairy and milk inspectors are employed without experience or technical knowledge of dairying. Where such men are employed, the committee believes that dairy inspection is largely of police control type, unsympathetic in its policies, and in too many instances inefficient in its accomplishments. Where a minimum educational requirement is established, it is believed that constant progress will be made in the improvement of the quality of milk in establishing public confidence in inspection.

Dairy inspectors must meet dairy farmers of all degrees of educational training; the health officer and his assistants and other members of the medical profession; the courts and members of the legal profession; the representative citizens of the community who are interested in important community problems, of which an adequate, safe milk supply is one of the most important; the leaders in community enterprises; chambers of commerce; public welfare organizations, such as the Red Cross, women's clubs, and the Parent-Teacher Association; city and village officials; business men, and operators of dairy plants. The dairy inspector should be able to meet the individual or the group. He should understand their point of view, and in his work get results without making enemies. This demands, in addition to technical training, both tact and a pleasing personality.

The committee believes that if progress along the lines described is to continue, the man selected as dairy control official should be graduated from an agricultural college or from an accredited veterinary college. The subjects recommended for the curriculum should include dairy chemistry, bacteriology, physics, dairy sanitation, and economics. The inspector should have some knowledge, either by experience or otherwise, of the principles of the manufacture of butter, cheese, ice cream, and other dairy products, the production and handling of market milk, and the operation of dairy machinery.

* Report of Committee of International Association of Dairy and Milk Inspectors, 1928.

Dairy chemistry should include not only a thorough training in the testing of dairy products, but some fundamental knowledge at least of organic chemistry and biochemistry. Bacteriology should include general instruction in the principles of bacteriology and a specialized course in the bacteriology of dairy products and in pathogenic bacteriology.

In addition to a complete course of instruction as described, the candidate should have had at least two years' experience or contact with some branch of the dairy industry.

The committee realizes that there are instances where men are available for dairy control work who have had unusual training and experience, and who are, therefore, well qualified to carry on effective dairy control work, although they have no degree from an agricultural college. To cover such cases, a city or state civil service board may include under "education" a statement to the effect that equivalent training, including a knowledge of dairying, together with some college training, may be accepted in lieu of a college degree.

Although the age at which a man may do the most effective work in dairy inspection cannot be definitely stated it is believed advisable to restrict the age of an applicant to the period 21 to 45. Men older than the maximum given may be efficient as dairy control officials, but it is believed that their work in later years will be more satisfactory if they decide to follow this line of work earlier in life.

Some civil service commissions have required that candidates for examination be residents of the city or territory in which the work is to be done. The committee believes that this requirement should be waived in the case of dairy inspector, since the work calls for special qualifications. Such a restriction often works detrimentally, in that some municipalities would be forced to select from a list of unqualified applicants. It is recommended, therefore, that the residence requirements be waived in order that all well qualified men may be given an opportunity to compete in the civil service examination and to qualify for the position.

The committee is of the opinion that the title "dairy and milk inspector" is open to criticism. It does not properly indicate the dignity or responsibility of this profession, nor is the title descriptive of the knowledge and training necessary for modern control work in order to stimulate the interest of the better trained and higher type of men.

With a view of a possible selection of a more appropriate title by the association, the committee recommends for consideration the following titles: "Dairy Supervisor," "Dairy Control Officer," "Chief Dairy Control Officer," "Chief of the Division of Milk Control," or

"Chief of the Division of Milk and Dairy Sanitation." The titles of assistants should be the same except for substituting the term "Assistant."

THE PRESENT SITUATION

To understand the need for recommendations in the field of educational requirements for dairy and milk inspectors, it is necessary that we inform ourselves concerning the present situation. Accordingly, the number of inspectors, the provisions for civil service, and educational requirements for the several types of political subdivisions (cities, counties, states, etc.) are given in Table I.

It should be recognized that it is always difficult to compile such a report and at the same time have it absolutely free of discrepancies, primarily because of the vagueness of the replies in some of the questionnaires. Some states reported a uniform state-wide system of market milk inspection, but the balance of the information submitted indi-

TABLE I

GENERAL SUMMARY OF REPLIES TO QUESTIONNAIRE SENT OUT TO STATES AND CITIES

1. Number of states replying	42
Number of states not replying (Georgia, Louisiana, Mississippi, North Carolina, North Dakota, Oregon, Texas)	7
2. Uniform state-wide system of market milk inspection.	
a. Number reporting Yes	5
b. Number reporting No	37
3. Correlating agencies.	
a. State agricultural or dairy departments reported by	27
b. State department of health reported by	12
c. Others (as state college, etc.) reported by	1
d. Gave no answer	2
4. Civil service requirements (reported by states).	
a. Number of states requiring civil service	9
b. Number of states not requiring civil service	25
c. Number of counties requiring civil service	1
d. Number of counties not requiring civil service	22
5. Educational requirements (reported by states).	
a. Number of states which demand special educational qualifications	7
b. Number of states which do not demand special educational qualifications	26
c. Number of counties which demand special educational qualifications	0
d. Number of counties which do not demand special educational qualifications	25
e. Number of cities which demand special educational qualifications	1
f. Number of cities which do not demand special educational qualifications	22
6. Report from city health departments.	
Number of replies	51
a. Civil service required by	26
Civil service not required by	24
Gave no answer	1
b. Special educational requirements specified by	11
No special educational requirements specified by	38
Gave no answer	2

cated so clearly that they did not have a uniform system that these cases were recorded as "No."

There is apparently a conflict in some of the answers to the questions regarding the educational and civil service requirements. In a few instances it was stated that prospective candidates had to pass civil service examination, but gave a negative answer in their replies to the questions regarding the educational requirements demanded. Civil service implies a certain amount of educational training. The committee had in mind primarily a more special training, such as a college degree in agriculture or veterinary medicine, or, in occasional instances, a training based upon a few years of successful experience.

Government Aid to Housing

SEVERAL investigations made in Europe within comparatively recent years have shown the effect of bad housing on the health of the people. For this reason the governments of several countries have taken measures to aid in the building of workers' houses.

Austria, for instance, permits the government social insurance organizations to loan for the building of workingmen's houses as much as 20 per cent of their capital.

In Germany, the public old age and invalidity insurance funds invested in popular housing nearly 200 million gold marks between the end of 1923 and the end of 1927. One hundred million marks was invested in housing by the National Institute for the Insurance of Clerical Employees between January 1, 1927, and June 30, 1928.

In Italy, the government organizations carrying insurance against industrial accidents, invalidity, and old age are permitted by law to make loans for the building of workers' houses up to one-fourth of their annual receipts; in the last few years these receipts have been, on the average, in excess of 5½ billion lire.

In France, the government is lending money to builders of low-priced dwellings. The budget for 1928 provided for that purpose more than 862 million francs.

In Belgium, the budget for 1928 provided an appropriation of 7,300,000 francs for special premiums to builders of working-class houses.—*Le Assicurazioni Sociali,* Rome, vol. 5, 1929, No. 3.

A New Suspending Medium Used for the Intracutaneous Virulence Test of Bacillus Diphtheriae*

R. V. STONE AND CATHERINE WEIGEL

Bureau of Laboratories, Los Angeles County Health Department, Los Angeles, Calif.

WORKERS in public health who are associated with diphtheria control realize that microscopic diagnosis does not offer conclusive information regarding the pathogenicity of organisms.

Formerly many bacteriologists thought it necessary to inoculate guinea pigs subcutaneously with pure strains. Later modifications permitted the use of the subcutaneous method with a mixed field culture. An immunized animal served as control. Death of the unprotected animal with characteristic lesions evidenced the presence of virulent organisms. Although satisfactory, 2 guinea pigs were necessary for each culture and a period of 96 hours was required to complete the test.

An intradermal method was developed by Force and Beattie in 1922.[1] Field cultures suspended in physiological salt solution were injected into the skin of a white guinea pig. The test dose was 0.2 ml. One hundred units of antitoxin were given 5 hours later. Virulent cultures produced necrotic areas at the site of inoculation. Control animals inoculated at the same time received 200 or 300 units of antitoxin 5 hours earlier. This permitted several tests to be made upon one guinea pig. Experience in our laboratory demonstrated this to be a practical public health procedure, but the protective dose of antitoxin *could* inhibit necrosis if not used with considerable caution.

In 1927 Falk, Tonney, White and Jensen published Electrical Determination of Virulence on Diphtheria Cultures.[2] Later in the same year, they, with Mills, published Electrophoresis of Diphtheria Bacilli.[3] Their work was of considerable interest since it would make possible virulence determination of the majority of routine cultures, without requiring test animals.

The method consisted of determining variations of mobility due to

* Read before the Health Officers' Section, League of California Municipalities, San Bernardino, Calif., October 11, 1928.

the speed of attraction toward the anode of pure cultures suspended in an electrical field.

Experiments were conducted in this laboratory with the view of applying the results routinely. Eighty-seven pure cultures from cases were tested by both electrophoresis and animal inoculations; 56 were virulent and 31 non-virulent by the intradermal test. In the electrical test, 522 mobilities (which represented the average of 6 reversals of polarity for each pure culture) were measured, grouped according to the number of seconds required for the organisms to move the distance of 1 ocular mm.

TABLE I

By Intradermal Test		Electrophoresis seconds required to move organism 1 mm.
Virulent	Non-virulent	
8	0	2 to 3 seconds
23	6	3 to 4 seconds
21	8	4 to 5 seconds
4	5	5 to 6 seconds
0	12	6 through 15 seconds

It will be observed in Table I that 8 mobilities of from 2 to 3 seconds checked with the virulent animal test, while 12 of 6 seconds and over checked with the non-virulent test. However, in the intermediate zone, 3 to 6 seconds, 48 gave a positive and 19 a negative skin test.

The 67 readings between 3 and 6 seconds could not be interpreted in terms of virulence without the animal tests. Virulent strains tend to fall in the fast readings while non-virulent increase as mobility decreases. This confirms in part the principle of electrophoresis, but since virulent and non-virulent are not sharply divided, there is no differential zone to determine electrophoretically one from the other.

TABLE II

SHOWING FAILURE OF PURE DIPHTHERIA-LIKE ORGANISMS SUSPENDED IN PHYSIOLOGICAL SALT SOLUTION TO REACT INTRACUTANEOUSLY AS VIRULENT

Cavy Number*	1			2					3				4	
Strain Number	119	Wh10	387	250	8	260	113	221	270	260	778	119	45A	45B
Reaction (necrosis) as a field culture	NN	X	X	X	X	PN	X	X	PN	PN	NN	NN	PN	PN
Reaction (necrosis) as a pure culture	NN	NN	NN	NN	NN	NN	NN	NN	NN	NN	NN	NN	NN	NN

PN: Positive Necrosis—NN: Negative Necrosis—X: Not Tested

* All 4 cavies died within 48 hours with lesions typical of toxin poisoning. No antitoxin was given as a protective dose, since occasionally reactions were aborted by its use.

Other factors that lessen the practicability of this postulated principle include the age of the culture, the reaction and temperature of the distilled water, and its varying condition due to dissolved atmospheric gases or substances from the glassware, age of the suspension, and the difficulty of isolating pure cultures. Since there are no characteristic differences between colonies of virulent and non-virulent organisms, and a field culture can include both types, picking a virulent one is purely a matter of chance.

Falk and his associates checked their electrical readings by the subcutaneous animal test. We first attempted to check ours by the skin test.

As some of the strains in Table II were from severe clinical cases of diphtheria, it seemed evident that the intradermal test would not apply to pure cultures. In seeking an explanation of this, our experiments resulted in the development of a suspending medium in which toxic strains in pure culture would produce necrosis.

TABLE III

AGAR-PEPTONE-BROTH SUSPENSION OF PURE DIPHTHERIA-LIKE ORGANISMS INOCULATED WITH AND WITHOUT A PROTECTIVE DOSE OF ANTITOXIN

Strain No.	* Antitoxin used	Saline suspended	Agar-peptone-broth	
1196	No antitoxin given	No effect	Congestion	Cavy died in 24 hours
Dr. F5		No effect	Congestion	
263		No effect	Congestion	
30		No effect	Congestion	
1196	500 units given after test had been on for 4 hours	No effect	Necrosis	Cavy lived
Dr. F5		No effect	Necrosis	
263		No effect	Necrosis	
30		No effect	Necrosis	
1196	500 units given 4 hours before testing	No effect	Normal	Cavy lived
Dr. F5		No effect	Normal	
263		No effect	Normal	
30		No effect	Normal	

* Several tests were made to determine how many units of antitoxin were necessary to save the animal without affecting seriously the local reaction. Five hundred units gave the best results.

253 (mixed)	Pronounced necrosis	Negative
244 (mixed)	Negative necrosis	Negative
1196 (pure)	Pronounced necrosis	Negative
Cavy No. 14		
March 9, 1928		
242 (mixed)	Pronounced necrosis	Negative
245 (mixed)	Pronounced necrosis	Negative
154 (mixed)	Negative necrosis	Negative
Dr. F5 (pure)	Pronounced necrosis	Negative

As all cavies not protected with antitoxin died with post-mortem evidence of toxin poisoning, it appeared desirable to test *pure* cultures from 2 known positive field cases and 2 unknown. One hundred units of antitoxin were used on one test animal, the second receiving none. The protected pig failed to react with any strain as positive, while the unprotected pig was dead within 48 hours, showing pronounced subcutaneous edema, and adrenals a mahogany red. It was apparent, then, that at least one of these pure strains was toxicogenic but had failed to induce necrosis.

Various substances such as peptone induce local congestion through positive chemotaxis. Incorporation of peptone in the suspending inoculating fluid was tried, the result being slight congestion which did not persist long enough to develop necrosis. Experiments with various formulas designed to hold the inoculum mechanically at the site of injection developed the information which follows.

In *Formula C* peptone is used both as a nutrient for organisms and as a stimulant to induce the necessary local congestion. Agar is

Formula C—Stone-Weigel Virulence Test Suspending Medium (Agar-peptone-broth)

Oven dried agar	0.2%	0.2 gm.
Water to make		100 c.c.
Boil briskly to dissolve agar; then add:		
Peptone (Witte's)	4.0%	4.0 gm.
Sodium chloride (C.P.)	0.5%	0.5 gm.
Beef extract (Difco)	0.3%	0.3 gm.
Dextrose (Difco)	0.2%	0.2 gm.
Boil at this stage in double cooker.		
Adjust to pH 7.0		
Then add n/1 Na(OH)	0.7%	0.7 c.c.

Sterilize at 15 lb. pressure for 30 minutes, after tubing; 1 c.c. per tube. Cork tubes and seal with paraffine. Care must be taken to prevent evaporation of stored medium, since a very slight concentration increases the percentage of agar sufficiently to solidify the fluid. Different lots of shredded agar vary in "setting" property; so each new lot should be tested.

absorbed slowly. This prolongs the period of local congestion. Other ingredients favor active production of toxin within the tissue.

The following experiment substantiates our belief that pure cultures of *B. diphtheriae,* suspended in saline with pyogenic organisms, would produce necrosis intradermally, but not alone, and that *Formula C* combined with pure diphtheria organisms would give as good a reaction as would occur with mixed cultures. These tests were all made upon one guinea pig. A protective dose of antitoxin was administered 4 hours later.

Intradermal Injection of:

Salt solution	Negative skin reaction
Agar-peptone-broth	Negative skin reaction
Staphylococci in saline	Negative skin reaction
Streptococci in saline	Negative skin reaction
B. diphtheriae (No. 1196) in saline	Negative skin reaction
B. diphtheriae (No. 1196) with staphylococci in saline	Necrosis
B. diphtheriae (No. 1196) with streptococci in saline	Necrosis
B. diphtheriae (No. 1196) in agar-peptone-broth	Necrosis

The following experiment is representative of many tests with new strains isolated day by day. These gave conclusive assurance that the agar-peptone-broth method was practical for pure cultures.

Giving a relatively large dose of antitoxin was a safe practice where agar-peptone-broth was used for suspension. *Saline* suspensions of pure or field cultures were inhibited when antitoxin was used. The application of agar-peptone-broth suspension to field cultures was a natural sequel to its successful use with pure cultures. Experiments on 90 field cultures using saline and agar-peptone-broth suspensions provided unmistakable evidence of the superiority of the new medium over salt solution.

Further experiments demonstrated that agar-peptone-broth permitted the use of a relatively larger dosage of antitoxin than was pos-

sible with saline without interfering appreciably with the local reaction (necrosis). See Table V.

Cary[4] and others have pointed out that the virulence of an organism and its active toxicogenicity are not necessarily correlated. Strain Park No. 8 of *B. diphtheriae* is highly toxicogenic but of low virulence. In our system of intradermal testing, any pure strain producing necrosis should produce a soluble toxin in broth; any not producing necrosis should be non-toxicogenic. To confirm the reliability of skin reactions as a test of virulence 37 pure strains were tested as saline suspensions, agar-peptone-broth suspensions and as toxic broth filtrates. The demonstration of toxin in a Berkefeld filtrate was necessary, but the production of a powerful toxin *in vitro* was not desirable since test animals might be killed before skin reactions could be read. *B. diphtheriae* grown 6 days in the following medium produced a toxin which caused necrosis intracutaneously in one minim doses. Pigs protected with antitoxin remained normal.

Beef extract broth for toxin production:

2% Witte's peptone
0.3% beef extract (Difco)
Distilled water to make 1 liter
Adjust to pH 7.0 and add 7 ml. per liter of n/1 Na(OH)
Sterilize 15 lbs. for 30 minutes

The 37 pure cultures were grown in this broth, killed by addition of 0.4 c.c. of 5 per cent phenol, and passed through Berkefeld filters.

TABLE V

	Cavy No. 15	Cavy No. 16	Cavy No. 17	Control
Mixed Field Culture No.	Saline suspended—no antitoxin given for protection of test animal	Saline suspended—100 units of antitoxin given 4 hours *after* inoculation	Agar-peptone-broth suspended—500 units of antitoxin given 4 hours *after* inoculation	Agar-peptone-broth suspended—500 units of antitoxin given 4 hours *before* inoculation
422	Animal was dead within *36 hours.* Post-mortem showed subcutaneous edema and congested adrenals. Heart blood sterile.	No reaction	*Necrosis*	Normal at end of 72 hours.
357		No reaction	No reaction	
407		Slight welt	*Pronounced Necrosis*	
447		No reaction	No reaction	
395		Slight welt	*Pronounced Necrosis*	
434		No reaction	No reaction	
433		No reaction	No reaction	

They were tested in saline, agar-peptone-broth, and as toxin filtrates. The saline suspended failed to react in conjunction with 500 units of antitoxin. Twenty-one cultures reacted as positive in agar-peptone-broth and as toxin filtrates; 13 were negative by all three tests; 1 toxin filtrate became contaminated and did not react, though the agar-peptone-broth reaction was positive; 1 toxin filtrate gave a very faint reaction, whereas the culture in agar-peptone-broth was negative; 1 culture produced a slight necrosis whereas its filtrate was negative.

Table VI gives the result of 4 cultures representative of this series.

* Photographic reproductions of guinea pig numbers 20, 21 and 22 are representative of the reactions obtained throughout these tests.

SUMMARY

Virulence tests are reviewed briefly with citations of certain limitations in present accepted procedures.

Electrophoresis as advanced by Falk and his coworkers is compared with actual intradermal tests on guinea pigs. Eighty-seven pure cultures studied demonstrate the impracticability of applying the test to routine public health control practice.

The intradermal test with pure cultures does not produce necrosis when salt solution is used for suspension.

Agar-peptone-broth aids in the production of excellent intracutaneous reactions with pure cultures.

Animal inoculations of agar-peptone-broth with mixed field cultures give reactions superior to those produced with the same field cultures in other suspensions.

Comparative experiments show that necrosis production *in vivo* by the Stone-Weigel method parallels toxin production *in vitro*.

THE VERNES FLOCCULATION TEST FOR THE DIAGNOSIS OF SYPHILIS

DESPITE the great number of articles that continue to appear on the technical and clinical aspects of the various serological tests for syphilis, there is very little recent reference in English or American literature to the Vernes flocculation or " photometric " test. This lack of comment is undoubtedly due to the mechanically elaborate technic of the test, as well as to the difficulties of interpreting the results. Indeed, it involves not only a modification of the classic precipitation reaction between syphilitic serum and lipoid extractives, but an entire elaborate system of serum diagnosis and serum-controlled therapy.

The conditions under which serum and lipoid antigen are mixed are such as to yield not a sharp contrast between a precipitate or a high degree of turbidity for the reaction with syphilitic serums on the one hand, and a clear or opalescent solution for non-syphilitic serums on the other hand, but slight differences in the turbidity of the serum-antigen mixture, detectable when the mixture is examined with a special optical instrument, the Vernes photometer. Low readings on the turbidity scale are found in general in non-syphilitic cases, and high readings in syphilitic cases. The turbidity readings that fall between these extremes are found to occur in both syphilitic and non-syphilitic cases, the proportion of the former increasing with increase in the turbidity readings. This elaborate system of serum diagnosis is based on the contention that in the absence of syphilis the turbidity reading is a constant value for each individual, but may vary from individual to individual. The presence of a syphilitic infection causes this value to increase, the course of the disease being accompanied by variations in the Vernes reading. A low reading before treatment will, for ex-

ample, be accompanied by a higher reading after a provocative treatment. The value of the reading should, according to Vernes, decrease to the normal constant value for the particular individual, if treatment is correctly administered over a sufficiently long period of time.

The Vernes system thus admits of no absolute positive or negative report for a single test, nor can the readings be readily interpreted in terms of the accepted + + + + scale of the Wassermann reaction. The burden of interpretation becomes a matter of *probability* for a single reaction, and of *variability* or *constancy* as influenced by antiluetic treatment for repeated tests. Indeed a single moderately low Vernes reading cannot be classed as a negative reaction unless it is known to coincide approximately with the normal Vernes reading of the patient in question, a criterion which it is obviously impossible to apply in many cases.

By thus contriving to express the serum reaction in terms of quantitative variations of a qualitatively continuous property of syphilitic and non-syphilitic serum, Vernes has made a distinct serological contribution. The principle on which his test is based, and the procedures involved, might lend themselves to special theoretical studies on the chemical and colloidal changes in the serum that affect the reaction with lipoid antigen.

From a practical viewpoint, the Vernes test seems to have several distinct limitations. In the first place the test is very complicated in technic and requires a relatively large amount of serum, at least 15 c.c. and preferably 20 c.c. of blood being specified. Furthermore, the very quality of indefiniteness, in which lies its theoretical significance, seems to detract from the practical applicability of the test for diagnostic purposes. Most of the published studies deal in great detail with the syphilometric analysis of a few cases, relatively few summarizing tables being available in which the serological results with this method are compared with the clinical findings in a large number of cases. As an exception may be quoted the recent report of the serological conference held at Copenhagen in June, 1928, under the auspices of the League of Nations Health Committee. The data furnished in this report show that in a group of about 500 serums from syphilitic cases, the Vernes test returned 40 per cent positive, 14 per cent doubtful, and 46 per cent negative reactions. The most satisfactory Wassermann method tested at the conference showed on the same group of serums 42 per cent positive, 15 per cent doubtful, and 43 per cent negative reactions, while the best of the precipitation methods tried gave 61 per cent positive, 7 per cent doubtful, and 32 per cent negative reactions. At the same time in a group of about 400

specimens from non-syphilitic cases, the Vernes test returned 0.5 per cent positive, 10.2 per cent doubtful, and 89.3 per cent negative reactions. The Wassermann test gave no positive, 2.8 per cent doubtful, and 97.2 per cent negative reactions, and the precipitation test above referred to gave no positive, 1 per cent doubtful, and 99 per cent negative reactions. The Vernes test thus seems to be less sensitive than a satisfactory precipitation test, and less specific than either a good Wassermann or a good precipitation test.

THE CHAMBER OF COMMERCE AND HEALTH CONSERVATION

THE Chamber of Commerce of the United States of America at its Seventeenth Annual Meeting adopted a resolution which stated:

> The gratifying progress of recent years in extending the average span of human life gives good reason to expect further advance through concerted efforts, both for health conservation and for prevention of accidents which are constantly growing and cause the premature death annually of thousands of our citizens. In order to conserve life and health to the fullest extent there should be further development of national interest and of national activity. In efforts directed to this purpose the Chamber should participate and should enlist the widest possible coöperation on the part of its membership.

As a means of creating a nation-wide interest in health development the Chamber of Commerce has instituted a Health Conservation Contest among its member organizations and has asked the Committee on Administrative Practice of our Association to act in an advisory capacity. This contest, conducted as it will be by a responsible organization, should tend to arouse community interest and improved understanding, thus meeting fundamental need.

The Executive Board at its meeting on December 8, 1928, voted to approve of the coöperative undertaking by which the Committee on Administrative Practice will serve as technical advisers in the Health Conservation Contest carried out by the Chamber of Commerce.

In his greetings to the health officers called together by the Committee on Administrative Practice with reference to this activity, William Butterworth, President of the Chamber of Commerce, stated:

> The object of the competition as outlined is to assist in reducing economic losses in the United States due to unnecessary illness and premature death by means of activities carried on by local chambers of commerce or similar associations in cooperation with their official health agencies. It is now known that at least 130 chambers of commerce have active committees engaged in health conservation work, and, accordingly, the contest is designed to give recognition and credit to the work of these committees as well as those that will undertake activities of a health nature in the future.

The Committee on Administrative Practice of the American Public Health Association through the studies of public health administration and work on appraisal of city health service is in a position to advise the Chamber of Commerce, with the best interests of the profession and of public health promotion in mind.

The service plan for this technical coöperation is twofold in purpose: (1) supplying technical aid on request of the local health officer; and (2) the appraisal or evaluation of the health work and its collateral activities in a particular city.

The hope is to arouse the interest of the local citizens and crystallize their attention in such a manner that the important men and women as well as organizations will assume a greater interest, give more intelligent knowledge, and develop a sympathetic appreciation of the problems and program of their health officer, so that eventually they will constitute themselves real and vital factors in relation to health questions and their solution.

When committees of chambers of commerce and civic groups in general become interested in the health department, when mortality rates—rates incident to preventable illness, accidents and to physical disability—assume a definite meaning to these organizations and groups, then the economic disadvantages of higher rates will become readily apparent. The per capita appropriation for health work will then be a subject of study and we may look for and anticipate more comprehensive and intelligent budgeting. The business instinct of such a community can be relied upon to assert itself and the essential funds for a well defined health program will be more readily obtainable.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

How Many Scarlet Fever Exposures Contract the Disease?—During the two years 1927 and 1928, there were in Detroit 7,967 cases of scarlet fever, 6,615 of which were primary cases and 1,352 secondary cases. To these 6,615 primary cases there were 10,888 presumably susceptible immediate family contacts, or 1.64 contacts per case. In all, 12.4 per cent of these contacts, or 1,352, contracted scarlet fever. While 12.4 per cent was the average of secondary cases to contacts, there was wide variation in the secondary case rates dependent primarily upon the length of time the contacts were exposed to the disease. Secondary cases ranged from 19 per cent where the contacts remained at home with the patient, to 3.95 per cent among contacts removed to adult friends' homes. In all 2,970, or 44.9 per cent, of the primary cases were hospitalized. Of the contacts to these hospitalized cases 10.7 per cent developed scarlet fever while 14.5 per cent of those exposed to cases cared for at home developed the disease.

Table I gives the disposition of immediate family presumably susceptible contacts and the number of secondary cases developing among them.

From these figures we may conclude that if a member of your family contracts scarlet fever and you are under 16 years of age and have not had the disease, or a negative Dick test, your chances of avoiding the disease are best if you go to stay with some adult friend. You are approximately 5 times as likely to get scarlet fever if you stay at home with the patient. If you are unable to visit an adult friend but will

TABLE I

DETROIT SCARLET FEVER CASES IN 1927 AND 1928

Where Case Was Cared For	Primary Cases	Susceptible Family Contacts *	Secondary Cases	Per Cent of Contacts Contracting the Disease
Cared for in the hospital—Case removed within 3 days of onset	2,130	4,150	224	5.39
Cared for in the hospital—Case removed more than 3 days after onset	840	1,874	266	14.19
Secondary cases occurring after patient returned from hospital		5,534	155	2.80
Total cases cared for in the hospital	2,970	6,024	645	10.70
Case cared for at home. Contacts removed to adult friends' home	776	1,465	58	3.95
Cared for at home—Contacts at home with the patient	2,869	3,399	649	19.09
Total cases cared for at home	3,645	4,864	707	14.53
Grand Totals	6,615	10,888	1,352	12.41

* Members of the immediate household who are under 16 years of age and who have not had scarlet fever. Our assumption that they are susceptible is, of course, in that they have not been Dick tested.

have the sick person sent to the hospital as early as possible, your chances of getting the disease are only a little over 5 out of 100. If all contacts had gone to live with adult friends, there would have been 922 less secondary cases than actually occurred.

One might conclude that since only 12.4 per cent of family contacts under 16 years of age contract scarlet fever, the disease is not a highly communicable one. This assumption is, however, incorrect in that many of these contacts, whom we have presumed to be susceptible in the absence of any definite information to the contrary, are really not susceptible. During 1927 Dick tests made on 1,076 children under 16 years of age who had not previously had scarlet fever showed that only 291 or 27.04 per cent were susceptible. If we assume that 30 per cent of these contacts are susceptible, we change our number of susceptible contacts from 10,888 to 3,266 and our secondary case rate becomes 41.4 per cent instead of 12.4 We may conclude that while a great many people are not susceptible to scarlet fever, if you are susceptible to it and are exposed, you are quite likely to contract the disease. Of the 1,020 susceptible contacts (30 per cent of 3,399) who stayed at home with the patient, 649 or 63.6 per cent contracted scarlet fever.—*Weekly Health Rev.*—Detroit Dept. of Health, Aug. 10, 1929.

Venereal Disease Reporting in Philadelphia—Venereal diseases were made reportable in this city in 1918. Provisions were made for reporting by serial number in private cases and by name and address in institutional and clinic cases. Official records of cases reported were declared private and confidential, not accessible to the public or any person other than the official custodian of the same. Infectious cases, delinquent in treatment or otherwise constituting a public health menace, were made reportable and subjected to special investigation and disposition.

Such cases are reclaimed to treatment at sources of reporting, placarded and quarantined at home or removed to the Philadelphia General Hospital and there quarantined. Suspected and clandestine cases are investigated and properly disposed of from a public health standpoint. Every effort is made to identify sources of infection to known cases and when discovered, they are forthwith placed under immediate control. Home contacts are routinely investigated and examined for evidences of disease.

Introduced as a World War measure, under governmental supervision, the reporting and control of venereal disease came in on a popular wave. Following the return to peace these activities were sustained through the educational propaganda and vice repressive measures of the federal government in coöperation with the states. However, within recent years there has been an apparent slowing-up in these activities. The reporting of cases involving control has marked time or been actually diminished all over the country. In Philadelphia the following yearly case figures serve to illustrate this:

Year	*Cases*	*Population*
1918	1,833	1,781,346
1919	3,748	1,809,635
1920	2,716	1,837,924
1926	2,597	2,007,652
1927	2,918	2,036,000
1928	2,885	2,064,288

It may be conceded that the incidence trend of venereal diseases is on the decline, but not to the extent indicated by the reduction in the number of case reports. It has been estimated that about 60 per cent of cases of syphilis and 75 per cent of cases of gonorrhea are under treatment by the private physician. In this city only 17 per cent of the total number of cases reported are received

from the private physician. The World War case rate given this city was 37.3 per 1,000 population and the nearest approximation to this figure was 2.10 in 1919, and 1.44 per 1,000 in 1928.

It is evident that venereal disease case reporting in Philadelphia is not popular and certainly does not approximate the incidence of these diseases in a community of 2,000,000 inhabitants. As in the other communicable diseases, the health officer should be supplied with data on prevalence, geographical distribution, focuses of infection, etc., in order intelligently to direct measures for control. Such data can be supplied only by the reporting physician, and there should be no hesitancy on his part or on the part of the patient to comply with the law. The law not only protects the identity of the patient conforming thereto, but at the same time protects the innocent public from a potential focus of infection.—*Healthfax*, Philadelphia Dept. of Health, July 22, 1929.

LABORATORY

C. C. YOUNG

THE DEATH OF ANIMALS FOLLOWING INOCULATION WITH *B. SUBTILIS* OR SIMILAR BACILLI

RUTH GILBERT, M. D., AND MARION B. COLEMAN

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

WHEN wool, bristles, or other animal products are examined for the presence of anthrax spores, it is customary to inoculate mice or guinea pigs subcutaneously with washings or with cultures made from the specimens. If *B. subtilis* or similar bacilli are present in large numbers in the inoculum and some of the material accidentally enters the peritoneum, the animals may die, and even though the presence of *B. anthracis* cannot be demonstrated in the specimens studied, stained preparations made at autopsy from the spleens of such animals may contain numerous large Gram-positive bacilli.

In 1923, a man who had carried bales of wool for delivery to a factory developed anthrax. Wool from one of the bales thought to have been handled by the patient together with burlap from the wrapper was delivered to the Division of Laboratories and Research for examination. Pieces of the burlap and masses of wool were placed in broth, incubated overnight, and guinea pigs and mice were inoculated with the cultures. The next day the mouse inoculated with the growth from the burlap was found dead and the examination of film preparations made from the spleen showed bacilli very closely resembling *B. anthracis*. Cultures from the heart's blood and spleen of this animal, however, were found to contain motile bacilli. No evidence of the presence of anthrax spores could be demonstrated in the wool or burlap submitted.

A number of cases of anthrax developed among employees of a carpet factory in another locality, in 1928. Samples of wool used at the factory as well

as material from some of the cases of anthrax were examined at a local laboratory where it was reported that anthrax bacilli were isolated in a number of instances.

Seven of the cultures from these specimens were received at the laboratory in Albany for confirmatory examination. The bacteria present in 5 of them were nonmotile and proved to be *B. anthracis,* and 2 contained motile bacilli.

Another culture isolated from a lesion on the arm of a man who had been in an automobile accident was also submitted from the same laboratory. This culture was described as being similar to *B. anthracis* in morphology, with many of its cultural characteristics, and was said to have proved virulent for two mice. It was found to contain motile bacilli, and a guinea pig inoculated subcutaneously with 1 c.c. of a heavy suspension of the organism showed no signs of illness.

The cultures of large Gram-positive spore-bearing bacilli isolated from the various sources mentioned resembled *B. subtilis* morphologically, but they did not correspond to it exactly in all of their cultural characteristics. Mice and guinea pigs are killed when inoculated intraperitoneally with 0.5 c.c. and 2.0 c.c. amounts, respectively, of a broth culture of *B. subtilis* and the bacilli can be isolated from the heart's blood. Mice were killed by all of the strains of the Gram-positive bacilli studied when inoculated intraperitoneally with an 0.5 c.c. amount of a 6-hour broth culture, while a similar dose given subcutaneously was not found to be pathogenic for them.

This experience demonstrates that in the inoculation of animals with material to be examined for anthrax spores, it is well to make the injections subcutaneously on the thigh, or in some position where there will be no danger of the material entering the peritoneal cavity. In case the inoculated animal dies, it is important to make morphological and cultural examinations for the purpose of demonstrating that the bacteria are nonmotile and correspond in other respects to *B. anthracis.*

THE "STAINED SLIDE" MICROSCOPIC AGGLUTINATION TEST

Its Application to (1) Rapid Typing of Pneumococci, (2) Determination of Antibody

ALBERT B. SABIN

Littauer Pneumonia Research Fund of New York University and the Department of Bacteriology of the New York University Medical School, New York, N. Y.

THE microscopic method to demonstrate the agglutination reaction with minute amounts of serum and organisms has been found to give reliable results. The test is performed by mixing a suspension of organisms with the immune serum on a glass slide, allowing it to dry rapidly and treating the film with a suitable stain. Agglutination in this reaction apparently occurs within half a minute, and the process has then progressed sufficiently to be observed without difficulty with oil-immersion, lens magnification. Many investigators have made stained preparations of bacteria that were previously agglutinated

either grossly in tubes or by the microscopic hanging-drop method. Neufeld (*Ztschr. f. Hyg. u. Infectionskrankh.*, 1902, xl: 54) studied microscopically the reaction between pneumococci and their homologous serums. He observed a specific reaction, characterized not only by agglutination but also by swelling of the peripheral portion of the organisms, i.e., the capsule. He also demonstrated that the peripheral swelling never led to the dissolution of the bacteria, and that it was not a bacteriolytic process. He thought that this specific reaction could be observed only in the moist state without fixation, and therefore found it unsatisfactory for practical application. A specific reaction may also be observed after drying in air, and the resulting picture resembles that obtained by Neufeld by the moist cover-slip method. The organisms are found in clumps of varying size, each embedded in a deeply staining, homogenous zone. Neufeld's explanation of a swelling of the capsule seems dubious in the light of recent work on agglutination, and it seems more likely that the zone surrounding the bacteria represents a precipitation of antibody-bearing protein on the periphery of the organisms. Saline suspensions of killed pneumococci, broth culture, colonies from blood agar plates and organisms from the mouse's peritoneum were found to give the reaction equally well. There was no disagreement in the typing of pneumococcus obtained by this method with that obtained by the old macroscopic tube agglutination, provided the test was carried out on the same material.

The importance of obtaining an early diagnosis of the type of infecting pneumococcus, especially in cases of lobar pneumonia to be treated with serum, has resulted in the development of many methods. The microscopic agglutination test just described, since it required very few organisms, was expected to reduce the time for a determination of type. Attempts to type the organisms directly from the sputum were unsuccessful. The fact that in the microscopic test the sputum was exposed to the immune serum for a very short time only, was at first thought to be responsible for the negative results. Small amounts of sputum were accordingly mixed with varying amounts of serum, and incubated in sealed capillary tubes at 37° C. for different periods of time; these mixtures were subsequently smeared and stained. The unsuccessful results are due possibly to the presence of some interfering factor or unfavorable physical conditions in the substance in which the pneumococci are coughed up. Most of the sputa injected in the mouse's peritoneum are digested within 2 hours, and in 3 to 4 hours sufficient organisms may be found to carry out a microscopic typing test. Broth may be used as a culture medium in the absence of mice, but the mouse is preferred because its peritoneum is somewhat selective for pneumococci, and because results can be obtained in a shorter time.

The procedure for microscopic typing is as follows: One c.c. of a fresh sample of sputum is injected intraperitoneally into a mouse; 3 to 4 hours after injection some of the peritoneal fluid is obtained by capillary puncture. A glass slide is marked off into 4 parts, and a minute drop of the peritoneal fluid is expelled upon each one of the 4 partitions. The first is smeared with saline for control, and the others with a loopful of a 1–10 dilution of Type I, of Type II, and of Type III, diagnostic serums respectively. This dilution of serum is chosen largely to eliminate group agglutinins. The smears are made thin, so that they dry rapidly; they are then stained for ½ minute with a fuchsin solution (10 c.c. saturated alcoholic solution of basic fuchsin plus 90 c.c. distilled water). The stain is

washed off in running water, and the smears are examined with the oil-immersion lens. If a specific agglutination reaction is observed in one of the smears with diagnostic serum, the organism is of the corresponding type. If no reaction occurs in any of the smears, and pneumococci are clearly seen, a diagnosis of group IV is made. When it is desired to know whether the organism is one of the fixed types of group IV, a similar procedure is carried out with the corresponding diagnostic serums. Naturally occurring clumps of organisms differ in appearance from those produced by specific agglutination; they can be recognized by their occurrence in the saline control smear as well. Unless a fresh sample of sputum is used, many of the organisms will have undergone autolysis and therefore more time must be allowed for growth. Since the mouse is not killed, another typing can be done if the first one should show insufficient organisms, and after death of the mouse the type may be confirmed. In the case of Type III, sufficient organisms for a microscopic typing are present as early as 2 hours after injection. The appearance of the specific reaction with Type III differs from that obtained with other types of pneumococci, primarily on account of the larger size of the capsule. More than 400 cases have already been typed by this method at the Harlem Hospital with perfect agreement as compared with the results obtained by the older methods.

MICROSCOPIC ANTIBODY TEST

It has been suggested (Park and Cooper) that the dosage of antipneumococcus serum be controlled by an antibody test on patient's blood. Taking advantage of the fact that the microscopic agglutination test requires only minute amounts of serum, it was performed on patients who had just recovered from lobar pneumonia or whose blood had been rendered anti-bacterial by therapeutic administration. Positive tests were obtained only against the homologous types of pneumococci. The technic for carrying out the microscopic antibody test is as follows:

A drop or more of the patient's blood is taken with a capillary. This is either centrifuged or, after coagulation and synaeresis, a minute amount of serum is smeared with a loopful of a heat-killed, saline suspension of the type of pneumococcus for which it is desired to determine agglutinins. The drops are thoroughly mixed and smeared very thin; allowed to dry in air; and stained for ½ minute with the fuchsin solution recommended for the microscopic typing test. The specific agglutination reaction is obtained here, but the clumps tend to be smaller.

The sensitivity of this method was compared with the rapid macroscopic method of Arlyle Noble (*J. Bact.*, XIV: 287, 1927) and the regular macroscopic tube agglutination, and it was found to be 2½ to 3 times as sensitive as either of the other methods when a standard diagnostic serum was used for the comparison.

Observations, which aim to establish with the aid of the microscopic antibody test a more exact guide for the administration of antipneumococcus serums, are being collected at Harlem Hospital.

The microscopic agglutination reaction has also been tried successfully with *B. typhosus* and meningococcus. Probably it may be applied as well wherever the older methods of demonstrating agglutination are used, and more advantageously in many instances where, without loss of time, the older methods are either unsatisfactory or impossible.

NOTE: I wish to thank Dr. William H. Park and Dr. Jesse G. M. Bullowa for their kind coöperation and numerous valuable suggestions.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Heart Disease among Children and Young Adults—The crude death rate from organic heart disease has been slowly increasing. But when the mortality data for the various age groups are considered, it is found that the rise in the rate applies only to the higher age groups. Distinct improvement has taken place in recent years in childhood, adolescence, and in early adult life. Among the industrial policy holders of the Metropolitan Life Insurance Company the death rate from heart disease decreased from 24.8 per 100,000 in 1911, to 14.4 in 1928 for the ages 10 to 14 among males, and from 33.1 to 20.1 among females; in the 20 to 24-year group the rates decreased from 33.4 to 24.4 among males, and from 38.9 to 26.8 among females; in the 25 to 34-year group there was a decrease from 58.1 to 40.3 among males, and from 53.0 to 37.7 among females; and in the 45 to 54-year group there was an increase in the death rate from 288.6 in 1911, to 354.7 in 1928 among males, and from 236.0 to 252.4 among females. A rise in the death rates is shown for the 65 to 74-year group. In 1911 the rate for males was 1,649.5, as compared with 1,986.2 in 1928, and for females 1,422.8, as compared with 1,711.4. The fact that heart disease mortality is increasing after age 65 is not discouraging, since this is the age-range when approximately 60 per cent of the deaths from chronic cardiac conditions occur.—*Stat. Bull.*, Met. Life Ins. Co., 10: 1–4 (June), 1929.

Ten-Year Program for Children in Massachusetts—Since 1924 approximately 100,000 children have been examined in Massachusetts. It was found that infection with the tubercle bacillus is not as common as had been supposed. An analysis of the records showed that when children begin school life 20 per cent are infected. At age 10 approximately 28 per cent are infected, and at 15 years of age about 35 per cent are infected. Children are infected with the tubercle bacillus to the same degree regardless of nutrition or nationality if they are exposed to an open case of tuberculosis. Fifty per cent of the children who were said to be contacts reacted to the tuberculin test. It was found that children with extensive tracheobronchial glands and calcified nodules in the lungs often developed the adult pulmonary type of disease a few years later. By use of the tuberculin test it was discovered that only about one-third of the diseased cervical glands are tuberculous.

In the future the clinic will reverse the procedure that has been in use. The tuberculin test will first be given. All reactors will be X-rayed. Those showing evidence of tuberculosis or other pulmonary conditions in the X-ray film will be examined by a physician of the clinic.—Henry D. Chadwick, *New England J. Med.*, 200: 1,154–1,155 (May 30), 1929.

Scarlet Fever Carriers among School Children—Cultural examinations for hemolytic streptococcus were made on groups of school children in Arlington and Dedham, Mass. In the Junior High East School in Arlington, scarlet fever had been prevalent in the school district and 4 pupils were absent with the disease. Among the pupils of

the Junior High West School scarlet fever had prevailed in the school district, but not in the school. The disease was absent from both the Parmenter Grade School and the district. In the Dedham School and district the incidence of scarlet fever had been very high, with no reported cases for the previous 6 months. There were 297 children examined in the four schools, and 40, or 13 per cent, were found to be carriers. Of these, 33 said that they had never had scarlet fever. In the Junior High East School 11 per cent of the 97 children examined were carriers. Eight of these had never had the disease. In the Junior High West School 8 per cent of 50 examined were carriers, and in the Parmenter School 10 per cent of 50 examined were carriers. Twenty per cent of the 100 children examined in the Dedham School were found to be carriers, and 18 of these had never had scarlet fever. In the Junior High West and the Parmenter Schools the additional information relative to previous tonsillectomy was obtained. Seven, or 14 per cent, of the carriers were children whose tonsils had not been removed, while 2, or 14 per cent, were those whose tonsils had been removed.—E. A. Lane and E. A. Beckler, Carriers of Streptococcus Hemolyticus in Relation to Control of Scarlet Fever in School, *New England J. Med.*, 200: 1,283–1,284 (June 20), 1929.

Typhoid Fever in 1928—The Health Section of the League of Nations reports that during 1928 typhoid morbidity fell considerably in a number of countries. Notable among these was Germany, where there has been a steady decrease for 4 years. The number of cases dropped from 17,367 in 1925 to 7,068 in 1928. In the European part of the R. F. S. F. R. (Soviet Russia) there has been a continuous decrease since 1925 when the typhoid morbidity reached the high level of 105,062 cases. The figure of 39,445 cases for 1928 is the lowest recorded for several years. The United States also shows a steady decline in typhoid fever. In 1928, 24,335 cases were reported from 47 states. In 1925 there were 45,995 cases reported, and in 1927, 34,411 cases. Countries which showed a considerable decrease in 1928 as compared with 1927 were Bulgaria with 2,467 and 4,012 cases, respectively; Czechoslovakia with 7,795 and 8,020 cases, respectively; and Italy with 34,708 and 39,894 cases, respectively. The general decrease in the prevalence of typhoid fever in Europe may be attributed mainly to the improvement in water supply since the war. Countries where the prevalence of typhoid fever increased were: Denmark with 413 cases in 1928, as compared with 278 in 1927; France with 9,762 cases in 1928, as compared with 7,438 in 1927; and Hungary with 9,822 cases in 1928, as compared with 7,265 in 1927. In Japan the position has remained stationary for some years, the number of cases of typhoid fever being slightly greater in 1928 than in 1927.

There was no great change in the typhoid mortality rate for most countries in 1928, as compared with 1927. Decreases in death rates were shown for Austria with 2.5 per 100,000 population in 1927, as against 1.4 in 1928; Czechoslovakia with 8.8 in 1927, as against 7.9 in 1928; and Canada with 11.9 in 1927, as against 4.7 in 1928. A steady decrease in the typhoid death rate over a series of years is shown by several countries. In Germany the rate declined from 6.3 per 100,000 population in 1919 to 1.1 in 1928; in Austria from 9.7 to 1.4; in Portugal from 17.1 to 9.3; and in Czechoslovakia from 16.6 to 7.9. In the U. S. Registration Area the rate declined from 9.1 in 1919 to 5.5 in 1927.

The seasonal distribution of deaths from typhoid fever seems to reach a

maximum during the summer or early autumn months. This summer maximum is not, however, constant, even in countries with practically the same climate. The summer-autumn maximum is often followed by an increase in the curve of incidence of typhoid in the middle of winter, though the winter maximum scarcely ever attains the height of that in summer.—League of Nations, *Epidemiological Report,* p. 155 (May 15), 1929.

The Cancer Record of 1928—The crude death rate from cancer has been steadily increasing in the United States for the past 25 years. For 50 cities since 1906 the rate has increased from 71.6 per 100,000 population to 117.3, the highest figure thus far on record for American cities collectively considered. Of 143 cities, 83 showed an increase and 60 showed a decline in the death rate for 1928 as compared with 1927. Among the 10 cities with the highest rates for 1928 were San Diego, Calif., with a death rate of 214.7 per 100,000 population; Springfield, Ill., with a rate of 206.8; Sacramento, Calif., with a rate of 203.4; and Atlantic City, N. J., with a rate of 192.0. Of the 143 cities studied the rates in 1928 varied from 37.0 per 100,000 population in Highland Park, Mich., to 214.7 in San Diego, Calif. Cancer is apparently not influenced very much by population aggregates. Many of the largest cities in the United States have rates measurably below the general average. Detroit had a death rate of 72.4 per 100,000 in 1928; Los Angeles a rate of 91.5; and New York City a rate of 128.8.

In comparison with certain foreign countries the cancer death rate of the United States is not exceedingly high. For the year 1925 the average cancer death rate for the United States was 93 per 100,000 population. For the same year the rate for Denmark was 140; for Austria 139; and for Prussia 97. In the U. S. Registration States the general cancer death rate at ages 45 to 54 increased from 173.8 in 1920 to 185.7 per 100,000 population in 1925; at ages 55 to 64 the rate increased from 394.4 to 434.9; and at ages 75 and over the rate increased from 974.1 to 1,138.3. These figures show that the actual mortality from cancer in proportion to population is rapidly increasing irrespective of the tremendous progress which has been made in the treatment of the disease.—Frederick L. Hoffman, *Spectator,* 123: 3, 22–23 (July 11), 1929.

Congenital Syphilis among Dependent Children—A study of 1,000 children under the care of the Associated Medical Clinic in Philadelphia was made to determine the incidence of syphilis. The children studied were between 4 months and 16 years of age. Seventy-nine and one-tenth per cent were white and 20.8 per cent were colored. Definitely positive Wassermann reactions were given by 2.3 per cent of the children; 0.6 per cent gave a doubtful reaction; and 97.1 per cent gave a negative reaction. Of the 23 children with a positive reaction, 20 were cases of congenital syphilis and 3 of acquired syphilis. Forty-seven and eight-tenths per cent of the 23 children were white and 52.2 per cent were colored. The percentage incidence compared with the total number of white and negro children studied was 1.39 for the white and 5.77 for the colored children. Ten of the 23 children were within normal limits of weight; 5 were more than 7 per cent underweight; 4 were 10 per cent or more overweight, and in 4 the weight was not recorded.

A special study of 200 of the children between the ages of 4 months and 5 years showed that the incidence of syphilis in this group was 1.5 per cent. The percentage of illegitimacy in the group was strikingly high, 105, or 52.5 per

cent, of the 200 children being of illegitimate birth. Among the entire group of 1,000 children studied the percentage of illegitimacy was 17.3 per cent. The physical signs of congenital syphilis are often so obscure that it would seem advisable, at least in a clinic for dependent children, to perform a Wassermann test of the blood on every child.—H. H. Jenks and J. D. Donelly, *Am. J. Dis. Child.*, 37: 1,198–1,202 (June), 1929.

Peptic Ulcer—An analysis was made of 556 cases of gastric and duodenal ulcer admitted to the Peter Bent Brigham Hospital, Boston, Mass., from 1913 to September, 1926. Seventy-two and eight-tenths per cent of the patients were male and 27.2 per cent were female. The average age at which symptoms of ulcer were first noticed was 36.8 years. There were only 9 families in which peptic ulcer was known to exist. In addition there was a history of stomach trouble in 37, which was fatal in 19 cases. Five per cent of the patients had hypertension, and 6 per cent had generalized arteriosclerosis. No other disease occurred frequently enough in the past history to suggest an association with ulcer. The average duration of symptoms at the time of entry was 7 years. Sixty-three per cent had had symptoms for more than 2 years. Hyperacidity occurred in 50 per cent of the cases, and hemorrhage in 34.8 per cent. Cancer was found in 4.4 per cent of the cases with gastric ulcer. Twenty of the 556 patients died from ulcers; of these 8 died from hemorrhage and 6 from perforation of the ulcer without operation. Twenty-one died following an operation to cure the ulcers.

The results of treatment were observed in 460 cases which were followed for periods varying from ½ to 13 years. As a result of treatment, 37.8 per cent of the patients showed good results and 40.6 per cent were unimproved. Two hundred and forty-eight patients had surgical treatment. Of these, 44.8 per cent showed good results, as compared with 40.6 per cent who were unimproved. Medical treatment was given to 186 patients without a previous operation. The results in 29.8 per cent were satisfactory, as compared with 48.7 per cent which were unsatisfactory. The results of all forms of treatment showed that about 60 per cent of the patients were relieved after an average observation period of 4 years.

All evidence points to the fact that ulcer is a chronic disease and that all the present methods of treatment are merely palliative.—Edward S. Emery and Robert T. Monroe, *Arch. Int. Med.*, 43: 846–873 (June), 1929.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Occupational Poisoning in Manufacture of Luminous Watch Dials—This paper presents a general review of the hazard caused by the ingestion of luminous paint, with special reference to the New Jersey cases, and is reprinted from the *Journal of the American Medical Association* of February 9 and 16, 1929. This is an excellent summary of the facts concerning the radium poisoning cases in New Jersey and the various reports made on these cases by Dr. F. L. Hoffman, Drs. Castle and Drinker, Drs. Reitter and Martland, and Dr. Flinn. The report calls attention to the national survey of this problem that is being conducted by the U. S. Public Health Service.—Harrison S. Martland, M.D., *Month. Labor Rev.*, 28: 6, 1242–1275 (June), 1929.

L. G.

Radium Poisoning—The Bureau of Labor Statistics has just completed a study of the effects on the health of workers of the use of radioactive substances, especially in the painting of watch dials. Inspections were made in 31 establishments in which some 253 workers were directly subjected to possible exposure to radioactive substances. A total of 23 fatalities and 19 living cases were found as a result of this study. The largest number of cases was among watch dial painters, in all totalling 33. The period of service ranged from 14½ months to over 12 years. Apparently all of these workers were in the habit of pointing their brushes between their lips until this custom was prohibited in 1925.

It is recommended that special precautionary measures be adopted to protect the workers in this country against the insidious effects of radioactive substances. A rigid physical examination should be made of all prospective workers to insure their fitness for such occupation, and after employment thorough physical examination, including blood studies and radioactive tests, should be performed every 2 months. Continuous employment should be limited to 2 years.

The remainder of the recommendations refer to the condition and maintenance of the workroom, the storage of radioactive materials, and the handling of radioactive material by the worker. The case histories of 42 cases of radium poisoning are reported in some detail.—*Month. Labor Rev.*, 28: 6, 1200–1241 (June), 1929.

L. G.

Dry Ice—A New Industrial Hazard—The *Monitor* of April, 1929, calls attention to the fact that solid carbon dioxide, known as dry ice, has been the cause of 5 claims for injuries filed with the Ohio Industrial Commission. The ice is used to freeze the core or center of golf balls. Apparently, the practice has been to place these cores in contact with the dry ice and then at the proper time to remove them to a winding machine for completion. The removal of the core is accomplished by hand and apparently produces its effect through the local freezing of certain portions of this member.

In each of the 5 cases reported, the nerves of the fingers, hands, and forearms were affected to such an extent that a neuritis was produced. Twitch-

ing of the arms was an early symptom with numbness and an inability to distinguish between heat and cold, and finally in some cases pain and inability to use the hand. Two of the cases were mild with a 10 to 14 days disability. Others were more prolonged. In one plant a device was installed by which the cores were removed from the containers without contact with the hand. This appears to have eliminated the occupational hazard.—*Month. Labor Rev.*, 29: 1, 96 (July), 1929. L. G.

The Dust Hazard in the Abrasive Industry—This paper presents a second study of workers engaged in the artificial abrasives industry, the first study having been completed and published in 1925. Essentially the task undertaken was a review of the subsequent history of 79 men previously studied, and a comparison of the 1924 with the 1928 X-ray findings, and finally a report of the X-ray findings of the other group of workers who have been exposed to abrasive dust inhalation for 10 years or longer. It is concluded that the inhalation of artificial abrasive dust composed of aluminum oxide or silicon carbide will not produce disabling silicosis in the working period studied. The X-ray pictures failed to reveal any cases of third stage silicosis. The author feels that it is possible for men with arrested tuberculosis processes to work in artificial abrasive industry for a considerable period of time without relighting the processes.—W. Irving Clark, M.D., *J. Indust. Hyg.*, 11: 3, 92 (Mar.), 1929. L. G.

The Cost of Free Advice. Tuberculosis in an Industrial Group—As a result of this study, the annual tuberculosis admission rate among railroad employees was found to be 1 case per 800 persons. The cost to the hospital association for the treatment of far advanced cases was found to average $4,600; for a moderately advanced case, about $1,000; and for the minimal, about $500. It is pointed out that the underlying cause of delay in diagnosis appears to be a tendency on the part of the laymen and doctors alike to ignore the commonplace knowledge of the prevalence of tuberculosis and its earlier symptoms. The importance of being tuberculosis-minded is emphasized, and it is pointed out that free medical service without special attention to the prevention and detection of tuberculosis would not serve to control the disease in this industrial group.—E. W. Phillips, M.D., *J. Indust. Hyg.*, 11: 4, 107 (Apr.), 1929. L. G.

Chrome Poisoning—Attention is called to a recent summary of the available information concerning chrome poisoning which was compiled by the National Safety Council. This report calls attention to the use of chromates in the manufacture and preparation of chromium and chrome colors; color photography; match manufacture; the tar color industry; manufacture of wet batteries; bleaches of fats, waxes and ointments; textile printing; chromium plating; the staining of wood and chromium tanning. According to this report the occurrence of systemic poisoning is doubtful and bronchitis is but occasionally seen.

The more usual symptomatology is referable to the conjunctiva, skin irritation and ulcers on the hands and nasal mucous membrane. It is suggested that washing with a 5 per cent solution of sodium bisulphite is beneficial in that it renders the chromic acid radical inert, and zinc or borax ointment is recommended as a dressing for ulcers. As a wet dressing a lotion of equal parts of calamine and boric acid is suggested.

Preventive measures include the enclosing of machines for the grinding of raw materials, the use of local exhaust ventilation, the use of efficient respira-

tors and impermeable rubber gloves. The anointment of face, hands and arms with a mixture of petrolatum, 3 parts, and lanolin, 1 part, is suggested as a means of preventing skin eruptions.—*Month. Labor Rev.*, 28: 5, 1036–1037 (May), 1929. L. G.

The Noise Evil—The Berlin Chamber of Commerce has adopted 13 resolutions pertaining to the nuisance and danger of noise. These are translated and printed in full in the *J. A. M. A.*, 93, 5: 397–398 (Aug. 3), 1929.

Occupational Diseases: Definition, Cause, Prevalence, and Prevention—This paper was presented before the New England Health Institute at Hartford, Conn., April 23, 1929. It is a very interesting and inclusive contribution and defines occupational disease and shows how specific occupational diseases are the result of existing health hazards. That there are national peculiarities in occupational disease is at once evident when one realizes the national variations in occupation. It is pointed out that in 1924 there were 9 state departments of labor and 21 state health departments receiving, or supposed to receive, reports of occupational diseases, and a discussion is presented showing the functioning of these regulations in many states and territories.

Dr. Hayhurst has laid down 3 principles or provisions emphasizing that the cost of production should include the cost of health conservation in the presence of health hazards; knowledge regarding health hazards and the provision of safe and proper work places is a prerequisite of every employer; and finally the health of the individual is an affair of the state, since in dependency the burden naturally falls on the state. The provisions of the health department should include an occupational disease reporting law or regulation and an office or division of occupational diseases for investigative and research purposes.—Emery R. Hayhurst, M.D., Ph.D., *Month. Labor Rev., 29: 1, 29–51* (July), 1929. L. G.

The Present Status of Benzene (Benzol) Poisoning—The present-day standards for diagnosing benzol poisoning are classified in one state under symptoms of local irritation, of anemia, and of nervous symptoms, while the diagnostic criterions rest upon (1) exposure to benzene at work, which (2) together with any one or more of the symptoms outlined, should warrant a tentative diagnosis, while (3) the finding in addition of a red blood count of less than 4,000,000, or a white count of less than 5,000 in addition should warrant a positive diagnosis of benzene poisoning. However, true benzene poisoning may exist without any leukopenia, and, in fact, in the presence of a leukocytosis. The various circumstances in which normal persons may show some of the blood findings of benzene poisoning, particularly leukopenia, are next discussed. Again other simulating disease conditions must be considered. The infectious leukopenia of Schultz, or agranulocytosis, may occur in the streptococci and pyocyanic infections, with accompanying hemorrhage and inflammation of the gums.

The question of benzene as a toxic entity is somewhat controversial, since there are no published reports on the action of extraordinarily pure benzene. The commoner contaminants are hydrogen sulphide, toluene, and bisulphide of carbon (50% often), according to Herrington.

Lewin, Lehmann and Schwenke have all reported that purified benzene is less toxic than crude varieties. There is, however, no intent to deny or question the actuality of benzene toxicity. Yet a group of 40 japanners, who daily spent from 6 to 8 hours coating cow

hides with enamels containing from 25 to 60 per cent benzene, in a room without artificial ventilation, for a period of more than 10 years, and without regular medical control, have not developed one case of benzene poisoning, other than dermatitis. No claim has ever been made for compensation and medical service, or for loss of time. Such a situation invites a further study of the subject.

Despite Hamilton's contention in 1928, of the lessening menace of benzol poisoning in American industry due to an alleged marked decrease in its use in the past 6 years, McCord points out such is not borne out by statistics on the production of benzene for the period mentioned, and he exhibits a table taken from the U. S. Tariff Commission which shows that, whereas slightly over 60 million gallons were consumed in the United States in 1922, the amount reached 99½ million gallons in 1925, and was over 86 million gallons in 1927.

Need of further work with reference to benzene toxicity is therefore indicated, and the author suggests five different lines of investigation.—Carey P. McCord, *J. A. M. A.*, 93, 4: 280–283 (July 27), 1929.

Lead Dust Hazard—Dr. R. E. Lane (Manchester) read a paper on this subject before the Section on Occupational Diseases of the British Medical Association, in which he emphasized the respiratory tract as by far the most important portal of entry for lead. Normal, healthy people both excreted lead in the urine in measurable quantities and showed minor degrees of basophilia. In research he had carried out he had found a definite relationship between the lead in the atmosphere, the lead excreted in the urine, and the basophilia content: the basophilia could be used in estimating the hazard. "He supported the findings of Sellars that all lead workers have a normal punctate basophilia, and that its mere presence cannot be taken as a proof of lead poisoning." It was, however, a delicate index of the degree of absorption, and as such of great value in anticipating trouble.—*Lancet*, 5528: 283 (Aug. 10), 1929.

The Present Position of Silicosis in Britain—This subject was discussed by the Section on Occupational Diseases of the British Medical Association at its Manchester meeting. Dr. E. L. Middleton, H. M. Medical Inspector of Factories, pointed out that in the pathology of silicosis the particles of silica were phagocyted and the lymphatic channels contained deposits of these cells, which produced a reaction in the surrounding tissues, so that fibrous tissue formed which underwent contraction resulting in distortion, with loss of function of the remaining lung tissue. Sections of the lung showed nodules formed in a whorled arrangement of fibrous tissue, and often particles (if 5 mu in diameter) could be demonstrated by polarized light. When free from other dusts of an irritating kind, silica was inhaled by workers without suspicion that they were exposed to dangerous dust. Dyspnea was usually the first symptom, and might follow exposure at any time of 2 to 40 years. In diagnosis, the employment history should be exhaustively studied, while a careful clinical examination, and a radiographical examination by an expert are essential. Prognosis depended upon: (1) the amount of dust inhaled; (2) the period of time over which this acted; and (3) the occurrence of infective processes, tuberculous or non-tuberculous. If taken in an early stage it seemed that the disease could be arrested.

The industries in which silicosis occurred were the *Refractories Industry* manufacturing ganister and silica bricks, where a specialist medical board now carries out medical examination of all

of the 2,000 to 3,000 persons employed. In the *Sandstone Industry* where silica is most widespread, the diminishing incidence of silicosis is considered due to the application of water and mechanical methods of dust suppression. The *Granite Industry* showed complicated pictures because of the varying proportions of quartz, felspar and mica present in the rock. The *Slate Industry,* as the result of an inquiry, showed some evidences of fibrosis of the lungs, but the occurrence of actual disability within the ordinary working lifetime of workers was not clearly shown. In the *Grinding of Metals* where silicosis with tuberculosis was at one time extremely prevalent, the replacement of sandstone wheels with other types of abrasive wheels, such as carborundum, had greatly modified the affliction. *Sand-blasting* of metals and glass was a matter for serious consideration, and one to determine whether a substitute such as iron or steel grit could not be used. In *Pottery Manufacture,* " potter's asthma " was probably due to flint dust, but the evolution of dust is now controlled by the use of mechanical means. *Tin Mining* in Cornwall had a high mortality rate from tuberculosis, and it was shown that this was associated with silicosis. Now the drilling is done through hollow steel with a water feed. Silicosis also occurred in *Coal Miners* employed on hard headings. It seems that once enough silica had been inhaled to produce the nucleus of fibrosis, the following inhalation of coal dust increased the fibrosis and produced disability. Dr. Middleton pointed out that " there was no criterion of air dustiness which could safely be regarded as indicating freedom from risk of producing the disease."

Dr. P. Heffernan, Tuberculosis Officer, Derbyshire, in a paper on the biophysics of silica and the etiology of silicosis, considered the action of silica as physicochemical in nature, and that alkalis favored the formation of silica hydrosol which increased the development of silicosis, while substances such as carbon, coal dust or clay which retarded the formation of silica hydrosol, retarded silicosis. Silica was a normal constituent of plant and animal cells and had a place in therapeutics comparable to that of lime. Dr. Watkins Pitchford (South Africa) uttered a warning about wet operation, since siliceous mud was potentially siliceous dust.—*Lancet,* 5528: 282–283 (Aug. 10), 1929.

Occupational Diseases and Social Legislation—Social insurance against occupational diseases was first adopted in Germany in May, 1925. As the act brought under insurance only a small proportion, a new act was adopted February 11, 1929, which increases the number of listed occupational diseases from 11 to 22. The newer alterations concern cutaneous disorders, disorders of the muscles, bones and joints, from work with compressed air; deafness from excessive noise in metal working; silicosis (pneumonoconiosis) in sandstone quarries, etc., including coincident pulmonary tuberculosis; typical disorders of sailors (tropical diseases, typhus, scurvy); and infections among the personnel of hospitals, etc. " Accident insurance shall apply to occupational diseases irrespective of whether the disease is caused by an accident or by an injurious action that cannot be classified as an accident." All physicians are compelled to report every case of occupational disease, even though only a suspicion exists. If the fear is justified that an occupational disease will develop, a transitional benefit shall be paid which shall not exceed half of the full benefit and for so long as the worker refrains from working in the menacing industry. Sometimes disability benefit shall be paid in addition to the transitional benefit.—Berlin Letter, *J. A. M. A.,* 93, 6: 473 (Aug. 10), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Effect of Excessive Doses of Irradiated Ergosterol on the Calcium and Phosphorus Content of the Blood—Reference is made to the work of Hess, Weinstock and Rivkin (*Proc. Soc. Exper. Biol. & Med.*, 26, 199) in which it is reported that in young rats on a diet high in phosphorus and very low in calcium, serum calcium was raised to normal by the daily administration of 1 mg. of irradiated ergosterol. In the work here reported, adult animals were used and the calcium intake was not restricted. Rabbits were the experiment animals on unlimited diet of oats and cabbage leaves. One group received a daily dose of 0.5 c.c. of arachis oil, the second, 0.5 c.c. arachis oil with 10 mg. non-irradiated ergosterol, and the third, 0.5 c.c. arachis oil with 10 mg. irradiated ergosterol (irradiation in alcohol). Calcium and phosphorus determinations made periodically showed no change until 25 days after the beginning of the experimental dose. The following day, in the case of two rabbits increased amount of phosphorus was noted but the calcium was normal. Two weeks later the phosphorus was 50 per cent above normal, with a slight increase in calcium but no change in the controls. Post-mortem examination showed the calcium in the kidney and the urine was saturated with calcium salts. Since deficiency of vitamin D results in low blood phosphorus or calcium, or both, it was concluded that excess of this vitamin may result, depending on the diet, in high phosphorus or calcium, or both. In an experiment performed on young rats in which the irradiated ergosterol (0.1 per cent of the diet) was given for 14 days, loss of weight resulted and high inorganic phosphorus and increased serum calcium, respectively 50 per cent and 25 per cent above normal. The increase in inorganic phosphorus which appears to precede the hypercalcemia is being studied.—Leslie Julius Harris and Corbett Page Stewart, *Biochem. J.*, 23: 206, 1929.

Bacteriological Studies of Sulphide Spoilage of Canned Vegetables—Outbreaks of sulphide spoilage occur sporadically in sweet corn and pea canneries. Such outbreaks generally involve a substantial part of the season's pack, and in several instances the entire season's pack has been so heavily contaminated that salvage was impracticable. In this bulletin a report is made regarding the cause of the condition and the identification of the microörganism responsible. It is reported that sulphide spoilage, characterized by an odor of hydrogen sulphide and some darkening of the product but no swelling of the container, is caused by the growth of an anaerobic spore-forming thermophile to which has been given the name, *Clostridium nigrificans*. The organism is a thermophile growing at an optimum temperature of 55° C. *Clostridium nigrificans* has proved to be one of the most heat resistant bacteria. Exposed to a temperature of 100° C. at pH 7.0 the spores remain viable for as long as 8 hours. Processing at 118° C. (245° F.) for 70 minutes has not proved effective in destroying the spore of *Cl. nigrificans* in No. 2 cans of sweet corn. The organism was not pathogenic

when ingested by man, guinea pig, mouse, rat, or rabbit. It is desirable in the control of *Cl. nigrificans* to eliminate the foci of infection in the cannery and prevent the presence of spores in the product. The organism occurs in the soil, in manure and on sugar, and probably finds its way into the cannery in these materials, where it may set up a focus of infection. There is little possibility of the organism causing spoilage in vegetables other than peas and sweet corn.—C. H. Werkman, Iowa Agri. Exper. Station Research *Bull. No. 117*, May, 1929.

Hypervitaminosis and Vitamin Balance—Part II. The Specificity of Vitamin D in Irradiated Ergosterol Poisoning—The work here recorded was undertaken to demonstrate whether the effects of hypervitaminosis evidenced in young rats were due to the vitamin *per se* or to accompanying toxic substances as has been alleged. The British drug firm which supplied the specimen stated that their observation was to the effect that ergosterol irradiated in alcohol showed toxic effects but that ergosterol irradiated in oil without the use of alcohol did not show the usual hypervitaminosis. Three separate experiments were undertaken, one in which over-irradiated ergosterol was used; one in which oil irradiated was compared to alcohol irradiated ergosterol; and the third in which the ergosterol was irradiated without the use of a solvent. In the first experiment, over-irradiated ergosterol was prepared from a specimen of the irradiated product which had proved toxic.

Three groups of rats were fed the same basal ration supplemented with non-irradiated ergosterol, with irradiated ergosterol, and with over-irradiated ergosterol. In the latter two the concentration was the same, 0.1 per cent of the diet. Animals on irradiated ergosterol lost weight and appetite, showed diminished heart beat, and died in 20 to 34 days with post-mortem evidence of deposits of calcium salts in various organs. Those on over-irradiated ergosterol were comparable with those on the non-irradiated with no abnormalities evidenced on autopsy.

In a second experiment rats were divided into 3 groups, one on a diet containing 0.025 per cent alcohol irradiated ergosterol, one group with the same concentration of ergosterol irradiated in oil, and the third group, the control, without ergosterol. The results showed no difference in degree of toxicity between the two types of irradiated ergosterol, death occurring at the same time in both groups.

Post-mortem examination showed diminution of spleen, atrophy of thymus, and calcium deposits in kidneys, aorta and heart. In the third experiment ergosterol was employed which had been irradiated in a thin film in an atmosphere of nitrogen and was incorporated in the diet at 0.1 per cent level. While the animals grew almost normally, after 28 days the autopsies revealed extensive deposits of calcium in the internal organs as in the other experiments.

The authors believe that if the toxic effects were due to impurities in ergosterol, these would persist in the case of the over-irradiated product, at least, that it would be an unusual coincidence otherwise. The pathological symptoms of hypervitaminosis are discussed, the important features of which are remarkably high blood-phosphate, diminished pH of the feces, diminished heart rate, and atrophy of the thymus. There is both a low and high threshold value for vitamin D, below which typical deficiency symptoms appear and above which increased blood-phosphorus and calcification with or without increase in blood-calcium.—Leslie Julius Harris and Thomas Moore, *Biochem. J.*, 23: 261, 1929.

Studies on the Nutritive Value of Milk. II. The Supplementary Value of Inorganic Iron and Copper—A previous paper by this author (*A. J. P. H.*, XIX, 5 (May), 1929) records the production of anemia in young rats by feeding exclusive whole milk diets. A continuation of the milk feeding experiment made necessary a supplement which would prevent this anemia. Iron was the first supplement tried, a solution of ferrous sulphate being made so that 1 c.c. contained 0.4 mg. iron. The growth results were unsatisfactory as were those when ferric citrate was used. The condition of the rats resembled xerophthalmia. A colloidal solution of ferric oxide was prepared and fed at the same level but anemia developed, although the rats were in better condition than those on the iron salts. Copper was used and 0.16 mg. of the metal as copper sulphate was added to the milk of one group and 0.2 mg. iron as colloidal ferric oxide was given to the other group. The addition of iron alone resulted in good growth but did not prevent decreased hemoglobin. When the copper supplement was added, there was a response in weight and increased hemoglobin. Copper alone resulted in growth and a rise in hemoglobin content to normal. This is not attributed to iron impurities in the copper but since milk supplies only 0.1 to 0.2 mg. it is concluded that either iron is required for hemoglobin formation or that present in the milk is made more available by the copper. The work apparently indicates a deficiency of milk in copper as well as in iron content. No offspring has ever been produced from mixed lots of rats on this diet, indicating the possibility of an adverse effect of copper and iron supplements on reproduction.

The production of nutritional anemia offers an opportunity to study the nutritive effect of exclusive whole milk diets.—W. E. Krause, *J. Dairy Sci.*, 12: 242 (May), 1929.

Iron in Nutrition. VIII. The Ineffectiveness of High Doses of Iron in Curing Anemia in the Rat—Reference is made to a report (Abstract, *A. J. P. H.*, 18: 1058 (Aug.), 1928) that inorganic iron at a daily level of 0.5 mg. was ineffective in curing nutritional anemia in rats. It was observed, but not reported, that 2 mg. of iron would stimulate hemoglobin regeneration. This observation raised the question as to the purity of the iron, and an experiment was undertaken in which specially purified iron was used. Purified ferric chloride was fed to anemic rats at 2, 5 and 10 mg. levels daily, 6 days a week. Similar amounts of iron not especially purified were fed to other groups.

The growth curves and tables show that the unpurified ferric chloride increased the hemoglobin level over an experimental period of 14 weeks, while those receiving specially purified iron salts made no progress in hemoglobin regeneration and did not increase in body weight.

There were exceptions in 2 individuals on the pure iron which did show some regeneration and this is attributed to the possibility of excess reserves of copper. The authors conclude that this is the explanation of the conflicting reports in the literature as to the effect of iron salts on hemoglobin formation since the iron wire before special purification was a high grade product used for standardization.—J. Waddell, H. Steenbock, and E. B. Hart, *J. Biol. Chem.*, 83: 243 (July), 1929.

IX. Further Proof That the Anemia Produced on Diets of Whole Milk and Iron Is Due to a Deficiency of Copper—As the result of previous experiments on the influence of copper in hemoglobin formation, the question was undecided as to whether copper is the only element which can supplement iron in this phenomenon.

A commercial liver preparation (Eli Lilly and Company) was ashed and the copper separated from it by electrolysis. This electrolytic copper with the residue was fed to anemic rats at a level representing 0.3 gm. of the original preparation (0.05 mg. Cu). In addition, rats were fed 0.05 mg. Cu as copper sulfate. Hemoglobin level and body weight increased in the groups fed the electrolyzed copper and the copper sulfate, but the residue after electrolysis was not effective.

Another experiment was performed in which the liver preparation, a hydrogen sulfide fraction of the acid extract of the ash of this preparation, and copper sulfate were compared. The quantities taken provided for copper ranging in amounts from 0.001 to 0.05 mg. of Cu. In other experiments various liver preparations were fed introducing similar amounts of copper.

Not all of the results of these experiments involving 15 litters of rats are published, but the results are stated to be uniform for all of the additions of copper. Hydrogen sulfide fractions of the ash extracts were as potent as the preparations and equivalent to the copper introduced as sulfate.

The authors conclude that this is convincing proof that the diet deficiency is inorganic and that it is copper only.—J. Waddell, H. Steenbock, C. A. Elvehjem, and E. B. Hart, *J. Biol. Chem.*, 83: 251 (July), 1929.

The Effect of Diet on the Copper Content of Milk—As an extension of the work (Abstract, *A. J. P. H.*, 18: 1059 (Aug.), 1928) on the influence of copper in prevention of anemia in rats on a milk diet, the amount of copper actually present in the milk of cows and of goats has been studied, as well as the effect on milk in administering additional copper. Weekly samples of milk for a period of 4 weeks were taken from Holstein cows on standard ration. The daily intake of copper in food was found to be approximately 60 mg. At the end of 4 weeks, 5 times this amount (1.2 gm. of $CuSO_4 . 5H_2O$) was added to each cow's ration.

Samples of milk were also collected from various sections of the United States and analyzed for copper. The materials were ignited in porcelain dishes which had been previously extracted so as to be copper-free. The copper content of the milk from cows on the basic ration was found to average 0.15 mg. per liter, lower than most of the figures found in the literature. The milk after the supplement of copper salts was found to contain practically no more copper, indicating the copper content of the milk not to be increased by feeding additional copper in the amounts recorded in this experiment.

Milk from various sections of the United States varied from 0.123 mg. per liter (North Carolina) to 0.184 mg. per liter (Texas), indicating the copper content practically uniform under various conditions.

The copper content of goat milk was about the same as that of cows and the addition of 50 to 25 mg. of copper daily to the ration did not change the copper content of the milk. The authors point out that the amount of copper in milk samples confirms biological findings and conclude that the different rates of hemoglobin reproduction reported by investigators are due not to variations of the copper content of the milk but to contamination after production or to unknown sources of copper.—C. A. Elvehjem, H. Steenbock, and E. B. Hart, *J. Biol. Chem.*, 83: 27 (July), 1929.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

A New Theory of the Cause of Dental Caries—"The etiology of dental caries as taught today was first formulated by W. D. Miller. He showed that the bacterial fermentation of carbohydrate food particles remaining upon the teeth forms lactic acid, which attacks their mineral constituents, while the organic basis substance is destroyed by another type of bacteria. Thus a cavity is formed in the tooth.

"A further and important contribution was made by Bunting, who found that a certain type of bacteria, *Bacillus acidophilus,* is always present during the decay of the teeth.

"That this presentation of the cause of dental caries does not completely explain the varying occurrence of this disease is proved by the number of investigations that have been undertaken since the time of Miller. These investigators have felt that Miller's theory does not explain the disease in all its phases, as the following exceptions can be noted:

"1. Teeth do not *always* decay in the presence of food debris.

"2. There appears to be an increase in susceptibility to dental decay during pregnancy and systemic illness.

"3. Pulpless teeth often seem to be more prone to decay than vital ones.

"4. The occurrence of approximal decay, affecting only one of the two adjacent teeth.

"5. That mottled enamel, which appears to be poorly calcified, is not more susceptible to decay than normal enamel.

"We note, therefore, that the present theory of decay does not explain all its phases.

. . .

"The resistance of the teeth to decay may be explained by the presence of the dental lymph, which is normal only so long as that individual is in a healthy condition. This is as yet purely a theory, which, however, is based upon the following data:

"1. A system of channels has been proved to be present in both the dentin and the enamel.

"2. These channels have been proved by laboratory and by animal experiment to be permeable from the pulp chamber up to the surface of the tooth.

"3. Blood plasma is known to contain free mineral salts, which neutralize lactic acid in other parts of the body and vary in quantity, depending upon the health of the individual.

"It is therefore plausible that normal dental lymph passes through the dentin and enamel of the teeth of man as well as those of the dog, and that it neutralizes whatever acid it encounters, thus inhibiting dental caries. A great deal of work, however, remains to be done to check up various phases of this theory. Nevertheless, even in its present stage of incompleteness, this theory gives for the first time a logical explanation of all clinical exceptions noted at the beginning of this paper.

"My view of the factors governing the relation between dental decay and systemic health is stated concisely as follows:

"I. Exciting cause of dental caries. Carbohydrate food decomposes in the presence of bacteria, forming lactic acid (Miller).

"II. Predisposing cause. Quantitative and qualitative changes of the dental lymph, diffusing to all free surfaces of the crowns of the teeth: (a) Dental lymph is derived from the blood plasma: (b) if the mineral content of the dental lymph is sufficiently high, it will neutralize the lactic acid on the sur-

face of the tooth and no decay can result; (c) if the mineral content of the blood plasma is decreased through systemic illnesses, it causes a corresponding reduction in the character of the dental lymph and therefore an insufficient neutralization of the lactic acid, resulting in dental caries; (d) variations of the mineral content of the dental lymph are dependent upon the character of the blood plasma, which are in turn affected by the general health of the individual, thus establishing a close relationship between the enamel and dentin of the teeth and the body as a whole."—Charles F. Bodecker, D.D.S., F.A.C.D., *Dental Cosmos,* June, 1929.

A Plea for Simplicity—In this timely article, Dr. Griffith urges greater simplicity in the teaching of pediatrics. He finds several sources to blame for the lack of direct teaching of the principles which will be of use to the young practitioner who must work his way up through general practice. The graded course, excess of laboratory work, and the methods used in the teaching of pediatrics itself, all come in for their share of blame. " The question then is, what have we taught him (the medical student) upon which he can now fall back? How much has been taught by us as to the actual handling of the sick child, and, even more important, of the mother of the sick child? "

Dr. Griffith criticises his own teaching no less severely than that of others. He suggests that simplicity in teaching undergraduates might well extend to the teaching of graduates through medical literature, and remarks: " The inclosure in them of unimportant or confusing things is often true of our textbooks which frequently contain much that could well be omitted."

He also remarks that many of the articles published today " show only a disposition on the part of the writer to get into print ahead of someone else."

The *Standard Dictionary* definition of " pediatrics " as " the department of medical science that relates to hygienic care of children and treatment of the diseases peculiar to childhood " is accepted.—J. P. Crozer Griffith, M.D., *Arch. Pediat.,* May, 1929.

Ovarian Irradiation and Health of Subsequent Child—" Murphy delivers his second communication dealing with the health of children born following maternal pelvic radium or roentgen irradiation. An attempt has been made to determine the nature, seriousness and frequency of any disturbances of health or defects in development among these children, and to ascertain, if possible, whether the maternal irradiation was entirely or only partly responsible for such faulty structure or disturbances of function as may be found among them. From the study of the literature and from an estimation based on the replies to a questionnaire, it seems apparent that relatively few children have been born to women who were subjected to pelvic irradiation. Fifty-three women are reported on who received postconception pelvic radium or roentgen irradiation. Abortion occurred in 23 instances (43.4 per cent).

" Of the 30 children born at term, 12 (40 per cent) presented some more or less serious disturbances of health or development. These defects, in many instances, were quite serious and tended to conform somewhat to a type. Two hundred and thirty pregnancies are reported on, occurring in women who received preconception pelvic irradiation. Abortion occurred in 50 (21.7 per cent) instances. Of the 180 children born at term, 27 (15 per cent) presented some disturbance of health or defect in development. These defects were much less severe than those occurring in the preceding group and did not conform in any way to a type. There is as yet no definite indication that ovarian irradia-

tion, prior to fertilization, has any detrimental influence on the health or development of any subsequent children." —D. P. Murphy, *Surg., Gynec., Obst.*, June, 1929 (abstracted by *J. A. M. A.*, July 20, 1929).

Birth and Death Rates for 1928—The U. S. Public Health Service in its *Public Health Reports* for August 2 summarizes the provisional birth, death and infant mortality rates for 1928 as given out by the U. S. Department of Commerce. These are for the birth registration area exclusive of Massachusetts and Utah.

The birth rate dropped one point during 1928 (19.7 as compared with 20.7 for 1927). The highest rate was in North Carolina (27.5 per 1,000 population). The death rate for 1928 for the above group of states was 12.3 as compared with 11.4 for 1927.

The infant mortality, too, has gone up several points, showing a rate of 68 for 1928 as contrasted with 64.6 for 1927. Oregon showed the lowest rate, namely, 46.9.

Jolts like this, coming as they do about every other year or so, ought to be good for public health workers, teaching us humility. But it does not work out that way at all. Credit is always claimed for all reductions, but a discreet silence is maintained regarding increases. What a relief it would be if some time propaganda were to be replaced by statements of sober facts and a little more effort put into teaching the public what the facts really mean.

School Health Supervision in Detroit—For the past few years the city of Detroit has been carrying on what is generally recognized as a most interesting experiment in school health supervision. The following summary of present practice in that city is contributed by Dr. Don W. Gudakunst:

The so-called Teacher Health Inspection System has been in operation in the Detroit Schools since 1921.

It has met with the unqualified approval of the Board of Education, the school principals and teachers. The School Health Service, which is under the administration of the Board of Health, has found this plan to be of the greatest help.

All school teachers in the City of Detroit are given a course of lectures and demonstrations as to the means of detecting any physical defects, or any indications of defects of vision, hearing, tonsils, teeth, skin and posture. Each child receives an inspection from his teacher early in the school year. Those children whom the teachers find to have some indication of defects are referred to the school physician for a more careful examination.

By this means those children most in need of medical examination are assured of such care. In a school system as large as Detroit it would be impractical to give an examination to each child every year.

Analysis of the markings of the teacher and of the physician shows very high corre'ation. However, no notification of the defect is sent to the parent based solely upon the teacher's inspection. Her work is used merely as a screen to pick out those children most urgently in need of medical care. This system has proved so popular in Detroit that it has spread on a purely voluntary basis from a few schools in 1921, to all of the public schools for the past few years, and now has been taken up by many of the private and parochial schools.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Looking Ahead—The student nurse of today is the public health nurse of tomorrow, and the public health nursing group has a very direct responsibility for following and aiding the work of the League of Nursing Education. Much good has come to the nursing profession through legislation since the days of Florence Nightingale, but "there's many a slip" in laws already passed, while excellent bills, awaiting legislative action, meet with little or no success. The article by Miss Burgess embodies the ideals of the National League of Nursing Education, and enumerates three projects, necessary for further advancement of nursing education, which need legislative action. While this subject seems to be fundamentally a League problem, it pertains to public health nurses also because, if we really function to any great degree in the community, matters of legislation will affect us materially.

The purpose of the League is the advancement of the education of the nurse. First, it is interested in the preparation of women in the "knowledges, skills, technics and qualities needed by everyone who is to give good nursing care, and second, in the further preparation required by those who would enter special forms of nursing service." Briefly then, its objects are service, higher education, and research. It attempts to determine and make possible the best education of the workers, and to promote better nursing service of all types.

The problems of today differ tremendously from those of the past. Now complicated treatments, diets and preventive measures require special skill. The committee grading schools of nursing will endeavor to show in what degree the skill is being provided, and bring to light one aspect of the nursing situation with which the League is greatly concerned; namely, the laws regulating the practice of nursing.

One of the earliest steps taken by the League was the establishment of a uniform curriculum—including qualifications, examinations, and percentage of excellence required, so that a universal standard might be maintained. Like everything else today, standards must be progressive to meet the ever changing needs, and legislation can keep them progressive.

In a few states, the law requires 8 grades of elementary school before a girl may enter a school of nursing; in others, she may enter after 1, 2, or 4 years of high school; while in 4 states the matter of education is left to the decision of the Board of Nurse Examiners.

The board sets up standards in the majority of states; inspects the schools; determines what shall be an accredited school; sets the examinations; and rates the candidates for the license to practice. The board may be composed entirely of nurses; the majority of its members may be nurses and the others physicians; the majority may be physicians and the others nurses; in 1 state, the board is composed wholly of physicians; and in another it is made up of nurses and one lay member. The law prescribes the professional qualifications

---

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

of the nurses on these boards, which range from graduation from a nursing school, to 5 years of educational work with nurses. This legal provision is meager, and a study of the individual qualifications of each member would be revealing.

Although we should be vitally interested in the amount and character of the clinical material provided for students, what is asked for in the laws is indicated by the bed capacity of hospitals, and the daily average of patients accepted.

Affiliations for the smallest schools with larger schools are not required by law in certain states. The Red Cross found this to be true when it penetrated the less populated areas, and accredited schools were stimulated to increase their service through affiliation, but this is by no means general.

There is great variation in the laws concerning the length of training which nurses shall have. Some states set 2 years as a minimum; others, 2 years and 4 months; while still others require 3 years in a hospital, thus making it impossible to add public health experience or give credit for college work. Where only minimum educational experience can be given, a minimum amount of time should be required.

There should also be a law requiring all those who nurse for hire to be licensed.

A national examining board, such as the American Medical Association evolved in 1915, would be helpful in solving the reciprocity question and in clarifying the standards of nursing education, and it would be the first step toward reciprocal relations with other countries.

To sum up, there are three important objectives to attain, which will require the combined help of the three national nursing associations; namely, the elevation of standards through the states, compulsory licensing, and provision for a national examining board.—Elizabeth C. Burgess, R.N., Advancement of Education through Legislation, *Am. J. Nurs.*, 29, 7: 765 (July), 1929.

M. A.

The Public Health Nurse's Lost Opportunity—Everyone realizes that the public health nurse in a community usually has easy entrée into the homes of her patients, and this is half the battle in doing preventive health work; but if when she gets into the home she is not observant and does not take opportunities to teach the family or individual members of it better ways of safeguarding their health, half of her effectiveness has been lost.

For instance, a new, well trained nurse interested in how the public health nurses in a community carried on their work accompanied several of them on their daily rounds. The first one was intelligent, a high school graduate, and had been in her position for several years. She had been asked by a school teacher to look into the condition of two of her pupils. One, a girl about 11, had poor vision, and her brother, age 8, could not talk plainly, and the teacher felt that he might be of retarded intelligence. The nurse had already made several visits to this family and had managed to get these two children put under a physician's treatment.

On this particular visit the observer noted that there were three other children in the family, including a baby 1 year old, walking with very bowed legs, and showing other indications of malnutrition.

The mother herself was very frail and looked haggard and worn. She casually mentioned that she had had malaria shortly before the baby was born, and that her mother had died of "consumption."

The nurse, despite the fact that she should have considered the family as a unit, was intent upon only one thing—

to get the necessary blanks filled out which would insure treatment for the two children whom the teacher had referred to her. Not a word was said about the physical condition of the mother, or whether she had recently or ever had a good physical examination. No question was asked about the baby's food, or the amount of sunshine or fresh air he got. The child welfare station in the community was not mentioned. Apparently in all her visits the nurse had never thought of mentioning these matters. The mother was grateful for what the nurse was doing for her two children; she was friendly and receptive —all the more reason the nurse should have seized her opportunity to do something constructive for her and her baby.

This is only one illustration out of many. In looking into the qualifications of this nurse it was found that she had had no theoretical training in public health nursing, nor had she had more than 6 weeks' experience in public health nursing under supervision while in training. For several years she had been working without supervision.

The *Appraisal Forms* of the American Public Health Association for both rural and city health work have set up standards for the number of visits a public health nurse should make in behalf of infants, preschool children, school children, tuberculous cases, communicable disease cases, and others; but what assurance is there that, even if the organization puts forth the effort to get the required number of nurses to make all these visits, the quality of their work will be such as to justify the effort?

Nowadays at least a year on the staff of a good public health nursing association or health department, under a well trained supervising nurse, is necessary. A young nurse just beginning public health nursing work is pitifully lacking in observation of the needs, or opportunities to teach health lessons in the homes of her patients. That ability must come through gradual training, through a supervisor who accompanies her on her visits and, in a constructive way, brings out points in the visit that the nurse would never think of, and through staff conferences and demonstrations both in the office and in the home. To get a broader perspective of public health in all its phases, at least 4 months of theory in one of the universities offering an approved course in public health nursing is necessary.

Nor can we be sure that the nurse even under supervision has had the right training unless we look into the experience and training of her supervising nurse, of the director of the teaching center (if there is one), and of the nurse director of the whole staff (if the organization is large). They, too, require both practical and theoretical training to get the full perspective and broad point of view their positions demand. The National Organization for Public Health Nursing can help out here, if anyone is in doubt.

Until all these requirements are met there will be many nurses doing public health nursing in communities who are not real public health nurses, because, while they may be adept at the mechanics of nursing, they lack the vision to see the family behind the patient and the community behind the family, which characterizes the good health teacher; and Mary S. Gardner says that it is principally as a teacher that the public health nurse has justified her existence.

A New Course for Public Health Nurses—At the present time there are in the United States 11 courses for public health nurses which have been graded by the National Organization for Public Health Nursing as meeting certain minimum requirements in regard to technical and practical instruction. These courses are conducted in the following universities or colleges throughout the United States:

University of California, Berkeley, Calif.; Simmons College, Boston, Mass.; University of Michigan, Ann Arbor, Mich.; University of Minnesota, Minneapolis, Minn.; Teachers College, Columbia University, New York, N. Y.; Western Reserve University, Cleveland, O.; University of Oregon, Portland, Ore.; Pennsylvania School of Social and Health Work, Philadelphia, Pa.; George Peabody College for Teachers, Nashville, Tenn.; College of William and Mary, Richmond, Va.; and the University of Washington, Seattle, Wash.

This fall the School of Nursing of Washington University, St. Louis, Mo., will offer a course in public health nursing, with the coöperation of other departments of the university and of the following organizations: Health Department of the City of St. Louis, State Board of Health Rural Teaching Center, St. Louis Visiting Nurse Association, and St. Louis Provident Association.

Negotiations for affiliations with other agencies will proceed as rapidly as possible.

The announcement continues:

The purpose of the course is to prepare qualified nurses for positions in the various fields of public health nursing.

Completion of the prescribed course will entitle the student to a Certificate in Public Health Nursing.

Requirements for Admission

1. Graduation from an accredited high school

2. Graduation from a course in nursing extending over a period of at least 2 years, conducted by a school of nursing connected with a hospital which has a minimum daily average of 30 patients during the candidate's period of training, and which provides experience in pediatrics, obstetrics, and medical and surgical nursing of men and women

3. State registration

(If a nurse meets the above requirements, she will also be eligible for membership in the National Organization for Public Health Nursing.)

4. Satisfactory condition of health as determined by a medical examination made by the University Health Service

Plan of Work

The program will cover one academic year of two semesters, a period of about 9 months. Registration begins September 19, 1929.

The first semester will be given chiefly to classroom work, assigned reading, lectures, and excursions. Courses in educational psychology, social science, public health nursing, mental hygiene, and public health and hygiene, totalling 17 semester hours, will be required.

The second semester's work will consist chiefly of field experience with health and social agencies, including special demonstrations, conferences, home visiting, clinic experience, and excursions. The selection of field work will depend somewhat upon the student's previous experience and her purpose in taking the course.

It is hoped that when the course is graded by the National Organization for Public Health Nursing, it will be put on the list of those approved by that organization.

Hitherto, there has been a large stretch of country between California and Washington and Minnesota and Tennessee without a course of this kind, and it should fill a long felt need.

Courses in Public Health Nursing for Graduate Nurses—National Organization for Public Health Nursing, New York, N. Y.

Public Health Nursing Course—Washington University School of Nursing, St. Louis, Mo.; Sept., 1929–June, 1930.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

"Too Much, or Too Little"—Thus *Editor and Publisher* characterizes a type of investigation publicity which sometimes tempts health agencies. A few weeks ago health officials reported that 9 of the 90 varieties of lipstick on the market "contained benzol, a chemical with puzzling and often dangerous reactions on human tissue. Face powders contained lead. Hair dyes did their job through the agency of a chemical containing most of the alphabet and heaven knows what else, but certainly poisonous. A few days previously, the seizure of a large quantity of impure and therefore deadly ether was reported from Boston." The editorial states the newspaper's interest in protecting its clientele and in keeping out advertisements of "merchandise branded as harmful by responsible public authority."

"Nine of the 90 lipsticks contain poison—but which 9? Some hair dyes perform with chemicals of baffling title and character—but is the article condemned on the front page the same one extolled in back-page advertising? No publisher knows. No reader knows.

"The inspectors who seized the adulterated ether in Boston mentioned no names. Neither did the New York cosmetic detectives. Amazingly, they protected the swindler and the potential poisoner, but slandered by implication every reputable competitor.

"It may be that the commercial chemists need a thorough going-over in the public interest and a few jail terms for conscienceless exploiters of human trouble. But it is sure that neither the industry nor the public will gain by investigations and seizures with a front page column as net tangible result and freedom to the offenders to continue their twisting in the hope that officialdom comes up for air only 'so often.'"

Do We Know What They Want?—Do we know what girls will read, and what will influence their health habits? These questions are prompted by a strikingly well done pamphlet of 16 pages addressed to girls—"It"—And How! written by Margaret Breen and issued by the Minnesota Public Health Association, 11 W. Summit Ave., St. Paul, Minn. *10 cents.*

In its aim of appealing to the desire to be popular "It" is certainly sound. We should think it would be successful, but if one could get the reactions on some of the more thoughtless young people who most need the advice it contains, it would be worth a lot more than anything health workers may say about it. Try-outs of the pamphlet conducted by someone not concerned with writing or publishing the pamphlet, and skilled in getting at the real attitudes of girls would be valuable.

In the frank use of an appeal to which we older people think girls will respond, in its lively and attractive illustrations, readable type, and good writing, "It" stands out from the mass of popular health publications. Some of the rather extravagant phrases are open to criticism. For example, on page 3, "without 'It' you are lost for you cannot keep up with the rest and you will be ignored," etc. All this, of course, is putting it rather strong.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Everyone concerned with public health education will wish to examine a copy, and probably many will try out a few copies for their own satisfaction. The editor hopes to receive some reports on the results.

This Same Question—Do We Know What's What?—is raised by The Kewpies Health Book, written and illustrated by Rose O'Neill—published by National Tuberculosis Association, 370 7th Ave., New York, N. Y. 5 cents; 100 for $2.00. It was an achievement to secure this 6-page folder from the creator of the Kewpies. Intended especially for use in kindergarten and primary grades. Kewpie fans, young and old, will love it. Mothers and nurse-maids will welcome it. It is something to slip into Christmas packages for children. Will it teach health habits? Who knows? But let's try it out.

National Publicity Groups—Paul Bliss, St. Louis Community Chest, 2221 Locust Street, St. Louis, Mo., is chairman of the Social Work Publicity Council. The executive committee includes: Frank Kiernan, Massachusetts Tuberculosis League; Katherine W. Whipple, New York Tuberculosis and Health Association; Virginia R. Wing, Cleveland Health Council.

Charles C. Stillman, Ohio State University, Columbus, O., is chairman of Educational Publicity Division, National Conference of Social Work. Bernard C. Roloff, Chicago Department of Health, and Virginia R. Wing, Cleveland Health Council, are members of the executive committee.

The next meetings will be in Boston, late spring of 1930.

TIMELY TOPICS

You will find unusually good leads for newspaper interviews and for paragraphs for your house organ in some of the changing customs and topics of general discussion offered during the past season. For example:

"The Hollywood Diet"—see editorial and "If You Want to Lose Weight," in *Better Health,* Dept. of Health, Syracuse, N. Y., Aug., 1929. *Free.*

A lively editorial, "The Eighteen Day Diet," appears in *Hygeia,* Sept., 1929. An abbreviation, "Hygeia Explains Hollywood Diet," is supplied free in *Hygeia Clip Sheet,* Sept., 1929. *Free.*

The problems of mechanical refrigeration are concisely outlined in *Health News,* U. S. Public Health Service, Washington, D. C. Ask for F–31–A. *Free.*

The past summer brought widespread discussion of the follies of men's clothing. Material for future use includes "What Is Rational Clothing?" answered in three mimeographed pages by League of Red Cross Societies, 2, Avenue Velasquez, Paris 8, France; and a radio talk by Dr. G. W. Goler, tells how men came to wear what they do, with a prophecy of better things. In *Health Bureau,* Bureau of Health, Rochester, N. Y., July, 1929. *Free.*

"Some 'Do's' and 'Don't's' on Ivy and Sumac Poisoning," *Clip Sheet,* Dept. of Agriculture, Washington, D. C., June 23, 1929. *Free.* Includes reference to *Farmers' Bulletin* 1166–F "as an aid to identifying the poison ivy plants and directions for treatments."

"Sun Tan Fashions Come from Switzerland, Say Tuberculosis Workers"—*Clip Sheet,* New Jersey Tuberculosis League, 21 Walnut St., Newark, N. J., July, 1929. *Free.* From Dr. Rollier to New Jersey sanatoria sun treatment. Also same *Clip Sheet,* under "The Song of the Skirt" touches on "the scanty clothing of the 1929 flapper" and quotes the old time "Song of the Skirt." (Incidentally beware of talking "flapper" much longer!)

"Modern Sun Worshipers"—Oregon

State Board of Health, July 30, 1929. Savage worship, modern tan and non-medical use of artificial sunlight. *Free.*

In "Beauty (?) Unadorned," *Woman's Journal* (Aug., 1929) says: "Just possibly when a girl finds that her back is not nice and flat she will take corrective exercises and will develop muscles to add to her grace, but we see no sign that that is to be the result." But publicity cleverly directed may bring that result.

REPORTING

What the Chicago Tuberculosis Institute is Doing (360 North Michigan Ave.) is told in 6 large pages of pictures with captions—and no statistics. *Free.*

In contrast, the Division of Social Hygiene, New York State Dept. of Health, in *Five Years of Social Hygiene Activities Presented Graphically,* uses 9 pages of diagrams to show quickly what has been done in education, clinics and laboratory services. *Free.*

A report in miniature is that of the Community Health Assn., Boston, Mass., which received special mention in the 1929 competition conducted by the Social Work Publicity Council. Said the contest committee: "It has a neat, appealing self-enclosed cover. . . . The list of services rendered . . . gives one the impression of conciseness and yet of a broad field of service. The chart of income and expenditure is vivid and the list of what specific gifts of money will do is appealing. The photos are not as good as they should be. The cost for 5,000 was $596." *Free.*

The readable descriptive report, without statistical data, is illustrated by a Review for 1928, Rockefeller Foundation. Size, paper, type, illustrations and text in combination produce an effective publication for semipopular use. *Free.*

Again the Milbank Memorial Fund in its 1928 report illustrates what can be done to present a readable, dignified record of a year's varied health and other social activities. While not "popular" in its appeal, the report is a recognition of the right of the student and the specialist to have reference material submitted in pleasing form. For the most part, the statistical data have been reduced to simple, clear diagrams. Illustrations appear on the same antique paper as the text. Bertrand Brown, in charge of publications, is prepared to demonstrate the comparative inexpensiveness of a well-printed report. The one disappointment is the lack of an index which would add considerably to the ready usefulness of the volume. *Free.* Address 49 Wall St., New York, N. Y.

THE OFFICE

Most of our mimeographed publicity looks dull enough even when it is neatly done. Too much of it is badly done. The best single help towards better and better mimeograph work is "How to Play the Mimeograph," by Dr. H. E. Kleinschmidt of the National Tuberculosis Association. This is an illustrated mimeographed pamphlet, entertaining and practical. Good for the "boss" who does the planning, for "Sally Ann" who cuts the stencil, and "Oscar" who finishes the job. Distributed only by Social Work Publicity Council, 130 East 22d St., New York, N. Y. *Send 4 cents postage.*

If you wish a duplicate set of any list in the form of typewritten cards, or a card record of the addresses made when envelopes are addressed, or a card copy of order slips or address stickers, or a card record of persons receiving notifications or communications—all made without extra typewriting when the original is typewritten—mention the JOURNAL and ask Direct Service Co., 604 Elwood Bldg., Rochester, N. Y., to send samples of sensitized cards.

Three commemorative 2-cent stamps have been issued recently—Sullivan Expedition, Edison, and Anthony Wayne. If not available locally, can be ordered through the Philatelic Agency, Post Office Dept., Washington, D. C.—if wanted to add a bit of distinction to your mail.

CHILDREN AND SCHOOLS

"Blue Ribbon Contests in Rutherford County." *News-Letter,* Commonwealth Fund, 1 East 57th St., New York, N. Y., June, 1927. *Free.* Annual parade of blue ribbon winners; growth of interest in the blue ribbon idea.

"Education in Good Posture," by J. Mace Andress. Introduction to a series of projects, with classroom material. *Hygeia,* July, 1929. Posture plays in both July and August issues.

"Health Education in Schools in the Metropolitan Health Demonstration Area," by Nina B. Lamkin and Mary E. Du Paul. *Quarterly Bulletin,* Milbank Memorial Fund, 49 Wall St., New York, N. Y., July, 1929. *Free.*

"Teaching Health in Schools." A reprint outlining the new state program of the State Charities Aid Association, covering health protection, health teaching, and health development. S. C. A. A., 105 East 22d St., New York, N. Y. *2 cents.*

"Your Nearest 'Service Station.'" A list of various units of the National Council to which correspondence about educational material may be addressed. *The Dairy Council,* 307 North Michigan Ave., Chicago, Ill., June–July, 1929. *Free.*

PUBLICITY NEEDED

"What Price Publicity," by Elsie M. Maurer. *Trained Nurse,* June, 1929, pp. 751–755. The need of more high grade applicants for training; the need of publicity in recruiting; how interviews, talks to visitors, correspondence and other routine contacts may have a far reaching importance unsuspected at the time.

DIPHTHERIA

The Illinois State Department of Health is distributing to physicians a display card advising parents to have their children immunized.

An anti-diphtheria cartoon from the *New York Evening World* appears in *Weekly Bulletin,* New York City Dept. of Health, July 6, 1929.

"What is Diphtheria?" is a 4-page mimeographed article distributed for reproduction in all countries. League of Red Cross Societies, 2, Avenue Velasquez, Paris, 8, France.

Three short paragraphs of explanation and history in *Time,* July 29, 1929, p. 50. Also New York City's use in July of street cleaning trucks as "healthmobiles."

MAGAZINE ARTICLES

"About Face," by Ruth F. Wadsworth. *Collier's,* Aug. 10, 1929. Beauty and the liver.

"Air Raids on Mosquitoes," by S. R. Winters. *Aeronautics.* In *Literary Digest,* June 29, 1929.

"Diet and Appetite," by T. Swann Harding. *Harpers,* Aug., 1929, pp. 361–369.

"Diet and the Duration of Life," by James A. Tobey. *American Mercury,* July, 1929.

"Too Much Tooth Pulling." *Journal of Indiana State Medical Assn.* In *Literary Digest,* July 6, 1929.

RADIO

Margaret Deland broadcast for the Massachusetts Social Hygiene Society recently.

"Have You a Family Doctor?" shows how the conversational form of expression and the economical use of words may result in a highly effective radio talk. *Health,* Dept. of Health, New Haven, Conn., July, 1929. *Free.*

A group of mouth hygiene talks—habits which affect teeth, why and when to straighten teeth, results of decay, what teeth should be extracted. *J. Am. Dental Assn.*, 58 East Washington St., Chicago, Ill., Sept., 1929.

"Health Hazards of Vacation Time"—a radio talk given July 2 when most people were all agog for a vacation, with or without "hazards." But the last paragraph of that radio talk was about "Goblins." It would have made a snappy lead for the talk—especially if the title had been changed to "Vacation Goblins."—*Conn. Health Bull.*, State Dept. of Health, July, 1929. *Free.*

HOUSE ORGANS

The mimeographed *Bulletin*, Board of Health, Middletown, N. Y., carries "home-made" illustrations in every issue, and the envelope used in mailing bears a new illustrated return card for every issue. *Free.*

Having asked its readers as to the value of the *Bulletin*, National Tuberculosis Association, the responses have determined its continuance with some changes in the editorial program.

"A List of Health Magazines in the United States" classified them as national, state or local. An attempt has been made to define the contents of the different publications. National Health Council, 370 7th Ave., New York, N. Y., May, 1929. 10 cents.

"The Feet and Their Care," in *Chicago's Health*, Dept. of Health, Chicago, Ill., Apr. 30, 1929. Good material for folder and other uses. *Free.*

"Serving the Destitute Sick," *Community Fund News*, 51 Warren Ave., W., Detroit, Mich., June, 1929. *Free.* On services rendered by doctors; record of free services in connection with one hospital. Quoting such statistics in the lead of a press release would carry the rest of the story in most newspapers.

TITLES AND PHRASES

"Feeding a Crabby Husband on Hot Summer Days." *Northwestern Health Journal*, St. Paul, Minn., July, 1929. *10 cents.*

BOOKS AND REPORTS

Teaching Health in Fargo—*By Maud A. Brown. New York: Commonwealth Fund,* 1929. 142 pp. Price, $1.50.

The tyro at reviewing who has the temerity to rush in upon *Teaching Health in Fargo* finds two pitfalls—the charm of the writing and the convincing way in which the subject is presented. Let it be repeated, Miss Brown writes. She does not grind out words, and in this respect her book is quite unique in health literature. Colorful expression, delicately humorous critical comments, and amusing illustrations in both words and pictures, all go to make the book a delight to the reader.

Then the presentation seems so rational, so obviously practical that the reviewer is tempted to sling superlatives like a school girl; so we become hypercritical and arm ourselves against the charm and persuasiveness of this little book as we subject it to caustic scrutiny. Is the conception new and worth reporting? Are the proposals sound pedagogy? Are the methods really practical under work-a-day conditions?

Certainly health educational schemes are as numerous as they are various. Projects, devices, concepts have all been tried piecemeal here, there, and everywhere. The outstanding contribution of the Fargo demonstration appears to be the wholesome teacher participation in planning as well as carrying out the scheme, for here was no predigested health educational pap jammed down the throats of mildly protesting teachers by some outside agency. This alone would make the demonstration worth reporting.

That its methods are sound pedagogically, those who have thought about health teaching will be fairly sure, for there will be found few artificial rewards to stimulate cupidity rather than health habits, and whenever tactful health educators work with normally interested, coöperative, and intelligent teachers, the methods should produce results in a measure comparable to those secured in Fargo. So we admit that caustic scrutiny fails to jar the enthusiasm of first reading. Sanitarians having to do with health teaching will enjoy and profit by this book, and they will want to get it quickly into the hands of those responsible for the health of school children if it is not already there.

RAYMOND S. PATTERSON

Stephen Hales, D.D., F.R.S. An Eighteenth Century Biography—*By A. E. Clark-Kennedy, M.D., M.R.C.P. New York: Macmillan,* 1929. 256 pp. Price, $6.00.

In 1927, Corpus Christi College, Cambridge, celebrated the 250th anniversary of Stephen Hales, and the author was selected to give the commemoration address. So much material was found that it was impossible to include it in an ordinary address, and the present work was written to complete the story of this remarkable man.

Although a clergyman, the name of Hales will always be connected with early experimental physiology and botany. He studied the ventilation of jails and ships, and devised apparatus for its improvement. His well known experiments on animals were a study of the blood pressure, and he was the first to introduce a cannula into the vessels and observe the height to which the blood would rise in a vertical glass tube. He studied the air, did re-breathing experiments, and concluded that it was through the peculiar properties of air

" that the main and principal operations of nature are carried out."

His life has particular interest for Americans because of his connection with the development of what is now the state of Georgia, which " was founded in an attempt to remedy the social conditions of England. . . . Georgia was both a philanthropic and an imperialistic enterprise."

One is somewhat astounded at the variety of his interests and the excellence of his work in each. He was perpetual curate of Teddington, and served that living for more than fifty years. He was a preacher of no mean ability, a plant and animal physiologist, one of our earliest hygienists and sanitarians, but in spite of all this he went wrong on a supposed cure for stone in the bladder, consisting of calcined snails, wild carrot seeds, burdock seeds, ashen keys, hips and haws, all burned to blackness, soap and honey, invented by one Joanna Stephens, though he was severe in dealing with other quacks. In this connection, he carried out a number of experiments in attempting to dissolve stones which had been removed, and in spite of his lack of success fell into the error of backing this particular cure.

As a biography, the work is exceptionally well done. The illustrations are numerous and beautiful, and prove Hales's ingènuity in devising and making such apparatus as well as his genius in working up the scientific problems. The author closes with an adaptation of words of John Wesley: " how well did science and religion agree in this man of sound understanding."

M. P. RAVENEL

Adventures in Health—*By Natalie Forbes Moulton. Boston: Little, Brown,* 1928. 140 pp. Price, $.70.

Buddie and Blossom have a series of adventures, first with the vegetables in the garden, then with animals who give them a lesson in the care of their teeth, with water and cleanliness, play times in the sunshine and numerous other incidents that indirectly teach the lessons of healthful living. This author, whose " Brownies' Health Book " has been so popular among teachers and primary grade children, has prepared another charming and interesting supplementary health reader. It has been delightfully illustrated by Eloise Burns.

ANNA B. TOWSE

Diseases of the Thyroid Gland—*By Arthur E. Hertzler, M.D. St. Louis: Mosby,* 1929. 286 pp. Price, $7.50.

Frankness, honesty and clarity are outstanding in this work of Hertzler. He is perfectly honest in stating the deficiencies in our knowledge of the thyroid, our ignorance of the etiology of even the commoner lesions, and the causes of the clinical manifestations. In stating these deficiencies, however, he opens up fields for further and new studies.

The subject matter and the material from which it is drawn are taken up by a master of pathology who in his zeal as a clinician and surgeon does not lose sight of the pathologic background—the cause of the disease, its manifestations, its progress and result. He views the problem from the point of the practical application of his science to the benefit and relief of the patient.

In studies of the thyroid, if the classification and terminology of its diseases were presented as Hertzler has done, in a clear, simple manner, there would be less confusion and misunderstanding. Clinicians and pathologists often lack in agreement of opinion concerning a thyroid, or a particular type or group of thyroids. This often does not represent a real difference, but a lack of proper understanding of these glands, and a common nomenclature and classification. Accurate clinical observations, gross and microscopic studies of the

gland should be available before a diagnosis is made on a thyroid.

It is a relief to read a present-day book on medicine in which the writer acknowledges the full value of laboratory work, but still insists upon the *tactus eruditus* of the "old school of medicine" that gave such men as Gross, Fenger and Senn.

By homely idioms and comparisons, Hertzler drives home many important facts that might otherwise receive little attention. He simplifies diseases of the thyroid to an extreme degree, yet omits none of the impressions and opinions of others whose writings often show such confusion of terms as to lose value when one tries to read, interpret and apply them.

The numerous illustrations are exceptionally good, well chosen and actually illustrate. M. PINSON NEAL

Who's Who among the Microbes—*By William H. Park, M.D., and Anna W. Williams, M.D. New York: Century,* 1929. 302 pp. Price, $3.00.

Good Health—*By Ian S. Thomson, M.D., D.P.H. New York: Longmans, Green,* 1929. 122 pp. Price, $1.40.

There is certainly no excuse for the public to remain in ignorance of the fundamentals of preventive medicine or medicine in general, as for some years past numbers of books—good, bad, and indifferent—have appeared, written for the general public, all of them couched in language intended to be non-technical.

The book by Park and Williams is the outcome of a series of radio talks on communicable diseases and the germs which cause them. It ends with a chapter showing the application of bacteriology to the ordinary affairs of life, and contains a number of simple illustrations, most of which are good.

The book by Thomson is different from the general run, and has the advantage of being much smaller. It goes more into the symptoms of the diseases spoken of, though cause and prevention are not neglected. Thomson is the son of Professor J. Arthur Thomson, than whom there is no better expositor of the biological sciences writing in the English language. This is the first book of his which has come to the reviewer's notice, but we hope it will not be the last.

Both of these books can be recommended without hesitation to those who, without special training in biology and medicine, wish to understand the fundamental laws of health and the reasons which underlie them.

M. P. RAVENEL

Oeuvres de Pasteur—*Tome 5. Etudes sur la bière, réunies par Pasteur Vallery-Radot. Paris: Masson & Cie,* 1928. viii + 361 pp., 12 pls., 85 figs. in text. Price, 120 francs.

The fifth volume of the collected works of Louis Pasteur edited by Pasteur Vallery-Radot contains the famous monograph on the diseases of beer, the causes which induce them, and the means of preserving beer from alteration. This investigation has a significant position in the historical development of Pasteur's career and is revealed in the phrase appended to the main title of the monograph, to wit: "with a new theory of fermentation."

This investigation afforded Pasteur another opportunity to reënforce his proofs of the non-spontaneity of germs, of the non-transformation of one species of microscopic germ into another species, and gave him the occasion to monograph the yeasts associated with alcoholic fermentation.

This monograph also records a notable expansion of Pasteur's comprehension of the significance of his discoveries as revealed in his chapter on the physiological theory of fermentation. In

this he concluded that fermentation is a very general phenomenon. It is life without air; it is life without free oxygen.

It is prophetic of his later achievements to find him asking if beer and wine undergo such profound alterations because they have given asylum to invisible microscopic organisms introduced by chance into their midst where they thrive, how can one escape the thought that facts of the same order might and should present themselves sometimes in man and animals.

A few supplemental papers in this field which were published in conjunction with the monograph and in later years, are added.

The epigraph from Bossuet with which Pasteur introduced this investigation might well shed its stimulating and restraining influence in every laboratory. "Le plus déréglement de l'esprit est de croire les choses parce qu'on veut qu'elles soient." C. A. KOFOID

Who's Who in America. Vol. 15, 1928–1929—*Edited by Albert Nelson Marquis. Chicago: A. N. Marquis Co.* 2488 pp. Price, $8.50.

In this, the 15th volume of this interesting and valuable compilation of the great, the near great, the celebrated, the noted and the notorious, there are 28,805 biographical sketches of living men and women who, the publishers are careful to state, are the "best known," though not necessarily the "best," in the United States.

On the whole, the public health profession is well represented and most of those who have attained renown in the field of sanitary science seem to be included. There are, however, some peculiar omissions. One looks in vain for the names of the health commissioners of several of our largest cities, and many of the state health officers are not among the elect. This fact may or may not be to the discredit of the editors who chose the personalities worth attention, but since certain legislators and high officers of the military forces are automatically included, regardless of their achievements, sanitarians in high official places might be so favored. Perhaps they are, but changes in office are so rapid that the editors cannot keep up with them.

It is, of course, too much of a task to attempt to take a census of all the sanitarians in *Who's Who*. The reviewer has, however, counted at least 21 sanitarians among the approximately 3,000 names beginning with "B." Among the 4,000 or so members of the American Public Health Association are more than 300 whose names commence with "B." Since the proportion of persons included in *Who's Who* is about one to every 4,000 of our total population, the ratio of sanitarians seems satisfactory. There are, of course, many practitioners of medicine listed in addition; and a few osteopaths, not to mention one or two naturopaths.

Sixty-four per cent of those mentioned in *Who's Who* are college graduates, and a number of others have had some college training, which is an interesting commentary on the value of an education, and is, no doubt, one reason for the 176 pages of advertisements of educational institutions at the back of the volume.

Who's Who is a reference book which should be in every library. It is interesting reading, for the perusal of biography is always worth while and not without inspiration. The book is well printed and arranged, and apparently unusually free from errors. Sanitarians will have many occasions to consult such a work.

Some day we may also have a separate volume devoted exclusively to Who's Who in public health. It would probably cost more than it would earn as a publishing venture, but it would serve a useful purpose.

JAMES A. TOBEY

Eat, Drink and Be Slender—*By Clarence W. Lieb, M.D. New York: The John Day Company,* 1929. 193 pp. Price, $2.00.

This addition to the outpourings on how to reduce is intended for general popular consumption. As such, it is a useful book, for the style is interesting and the facts are sound, with proper emphasis on the desirability of the prospective reducer consulting his or her physician. The book is divided into three parts, the first on the three types of obesity, the second on health hazards and complications, and the third on methods of reducing. Each has numerous short sections containing much of an epigrammatic nature. Physicians and sanitarians can recommend this book to their public with comparative impunity. JAMES A. TOBEY

Nursing Mental Diseases—*By Harriet Bailey, R.N. (2d ed. rev.) New York: Macmillan,* 1929. 294 pp. Price, $2.00.

It is difficult to conceive of a treatment of this subject that could be more complete or up-to-date or more clear and simple. The first edition has been held among nurses as a standard for psychiatric nursing and there is every reason to believe the revised edition will hold the same high place among them.

From a psychological introduction the author goes on to the history of the care of the mentally sick, to some legal aspects of mental disorders, and to the prevention of mental disease, before taking up the symptoms. She quotes an eminent physician as saying, "While signs are the province of the doctor, symptoms are in a peculiar way that of the nurse." For each type of psychosis she has given the physical symptoms, the mental symptoms, then the nursing procedures, followed by very helpful hints as to the simple occupations these patients can best take part in to keep them busy and happy and assist in bringing them back to health.

There are also good chapters on therapeutic measures and hydrotherapy.

The book should not only be the stand-by of every psychiatric nurse, but of every active nurse, for different grades of mental illness appear in all classes of patients whether they are in hospitals or their own homes. Moreover, if all nurses read this book more of them would take up psychiatric nursing, for Miss Bailey has made it evident to what extent judgment, tact, emotional stability, ingenuity and human understanding are necessary characteristics of the nurses who work with those mentally diseased.

The book is written in fairly large print and is easy to read. There is a good glossary. EVA F. MACDOUGALL

Die Menschenthymus in Gesundheit und Krankheit—*Ergebnisse der numerischen Analyse von mehr als Tausend menschlichen Thymusdrüsen. Teil II. Das Organ unter anormalen Körperverhältnissen. Zugleich Grundlagen der Theorie der Thymusfunktion. Von J. Aug. Hammar. Leipzig: Akademische Verlagsgesellschaft,* 1929. xii + 1114 pp. (815 figs.) Price, 128 M.

This is the concluding volume of Dr. Hammar's monumental study of the human thymus based on 25 years of intensive study and the analysis of over 1,000 cases of critical examination of the thymus, 800 of which were after death by disease or following some abnormal condition.

The present volume opens with a discussion of the general pathological anatomy of the thymus. This is followed by a general consideration of the physiological questions arising from the anatomical and pathological conditions of the gland and experiments based thereon. The functions of the thymus as revealed by the facts thus far ac-

quired are reviewed and this is followed by a chapter on the methodology of the investigation, well worthy of consideration by all who seek to analyse the causes of disease. The greater part of the work is taken up with detailed analyses of the conditions found in the thymus following death by the more prevalent diseases from influenza to lues.

Dr. Hammar regards the thymus as essentially an epithelial organ and Hassall's corpuscles as constituting the significant part. It is in them that hypertrophy and degeneration occur. The lymphocytes in the parenchyma are invaders subject to the action of factors modifying lymphocytes generally in the body, though they are subject also to a direct correlation with the epithelial portion of the thymus. An abundance of lymphocytes is a condition of the preservation of the epithelial components and is indicative of normal function.

The histological analysis and experiments based thereon lead to the conclusion that Hassall's corpuscles increase under the stimulus of certain toxins exogenous and endogenous in origin. The physiological evidence indicates that the thymus exercises a protective action against certain toxins.

C. A. KOFOID

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

The I. C. N. Congress—A résumé of the meetings of the Montreal Congress of the International Council of Nurses includes brief excerpts from some of the important papers.

ANON. The Congress of the International Council of Nurses. Pub. Health Nurse, 21, 8: 397 (Aug.), 1929.

Tetanus and Vaccination—Tetanus occurred in conjunction with vaccination only when some type of dressing was strapped to the arm. Deep implantation of the bacillus is necessary, which is permitted by a tight dressing. Openly treated vaccinations are free from this complication.

ARMSTRONG, C. The Rôle of the Vaccination Dressing in the Production of Postvaccinal Tetanus. Pub. Health Rep., 44, 31: 1871 (Aug. 2), 1929.

Good Shoes—Why feet go wrong and how they can obtain relief through good shoes is the theme of this uninspired series of wordy paragraphs.

BUKA, A. J. The Foot and the Shoe. J. A. M. A., 93, 6: 445 (Aug. 10), 1929.

Physical Defects and Intelligence—Physical examinations of more than 14,000 retarded school children in Massachusetts demonstrate the positive association, between the factors of physical defect and lower level of intelligence. Excellently illustrated with graphs.

DAYTON, N. A. The Relationship between Physical Defects and Intelligence. New England J. Med., 201, 6: 245 (Aug. 8), 1929.

Malaria Control Measures—Briefly reviews present-day methods for malaria control.

Health Nursing Problems—How to extend nursing service, to coöperate with fellow workers, to establish permanency, and a half dozen other important questions are presented and discussed ably in this paper.

GARDNER, M. S. Modern Problems in the Public Health Nursing Field. Pub. Health Nurse, 21, 8: 413 (Aug.), 1929.

Tests for Syphilis—The League of Nations conducted a competition to allow the proponents of the many diagnostic tests to demonstrate the advantages of each. At the conclusion, the conference recommended that two tests be used.

KAHN, R. L. The League of Nations Conference on Laboratory Tests for Syphilis. J. A. M. A., 93, 5: 351 (Aug. 3), 1929.

Wassermann or Kahn?—Another comparative study of the Wassermann (Kolmer modification) and Kahn leads these authors to believe that the Kolmer-Wassermann test is the more accurate, but both tests are recommended.

MCINTYRE, M. C., and GILMAN, R. L. Serologic Studies. J. A. M. A., 93, 5: 358 (Aug. 3), 1929.

Toxin-Antitoxin or Toxoid—The authors are of the opinion "that toxoid merits the preference in the choice of an immunizing agent in the prophylaxis of diphtheria." Score another for toxoid.

WEINFELD, G. F., and COOPERSTOCK, M. Comparative Effects of Diphtheria Toxoid and Toxin-Antitoxin as Immunizing Agents. Am. J. Dis. Child, 38, 1: 35 (July), 1929.

Impounded Waters—Should boating, bathing, fishing be permitted in impounded reservoirs? The author's opinion is that a freer use than is usually the practice may be allowed, providing precautions are taken.

ROSENTHAL, H. The Protection of Impounded Reservoirs. J. Am. Water Works A., 21, 8: 1054 (Aug.), 1929.

Industrial Tuberculosis—Chest injury, either trauma or by diseases related to injury, usually is the cause of the development or reactivation of the tuberculous process in industrial cases.

SHIPMAN, S. J. Industrial Tuberculosis. J. A. M. A., 93, 4: 257 (July 27), 1929.

Economic Status and Disease—Statistics are presented which show, what every sanitarian believed, that the illness rate is higher among the poor and that such people get less medical attention. Well, these figures will serve many a perplexed orator who is in need of just such help for his cause.

SYDENSTRICKER, E. Economic Status and the Incidence of Illness. Pub. Health Rep., 44, 30: 1821 (July 26), 1929.

Evaluating Sanitary Progress—The enthusiast who rushes in to "prove" the value of his pet panacea should read this sane discussion of the progress in public health.

ROATTA, G. B. Developments in the Public Health Field. Pub. Health Nurse, 21, 8: 403 (Aug.), 1929.

Early Symptoms of Tuberculosis—Cough, easily tired, loss of weight, appetite, pain in chest were the early symptoms most commonly met in an examination of 1,500 patients. Though these symptoms spurred the patient to be examined, physicians were frequently unable to establish a positive diagnosis.

WILLIAMS, L. R., and HILL, A. M. The Appearance of the Symptoms of Tuberculosis. J. A. M. A., 93, 8: 579 (Aug. 24), 1929.

Contributions of Hermann M. Biggs—The sanitary advances of the past fifty years and the leadership of Hermann M. Biggs are ably portrayed in this delightful memorial lecture.

WINSLOW, C.-E. A. The Contribution of Hermann M. Biggs to Public Health. Rev. Tuberc., 20, 1: 1 (July), 1929.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

East Orange, N. J.—The new health department building, according to the 1928 report, is one of a group of city buildings which form a civic center. Plans have been made for administrative offices to house the commissioners and health officer, the sanitary inspection, nursing, vital statistics and communicable disease divisions, and also for a completely equipped laboratory, and two principal clinics—one for the care of infants and children, the other for adults, including food handler examinations, venereal disease diagnosis and treatment, and such other functions as may develop in the future. As a means of enlarging the educational activities of the department, a small assembly hall will be available for lecture and conference purposes.

During the year standard swimming pool regulations have been prepared, and rules have been adopted for the quarantine of persons exposed to chickenpox and mumps, and for discontinuing the destruction or fumigation of books from quarantined premises. Health practices, based on the *Appraisal Form*, score 848 out of a possible 1,000 points.

The estimated population of the city is 68,764, and the figures are classified by wards, color, and nationality. Of 931 births, 74 per cent occurred in hospitals, while only 4.9 per cent were attended by midwives. While the native white parents constituted 82.5 per cent of the population, only 63.3 per cent of the births belong in this group. A death rate of 9.8 per 1,000 population compares with 9.0 in 1927, and 11.8 for the years 1914–1918. Of the total 681 deaths, 73.3 per cent were in the age group 45 years and over. An infant mortality rate of 43 per 1,000 births is noteworthy. There were only 21 deaths from tuberculosis, including residents who died in distant sanatoriums and out of town institutions, giving a specific rate of 31 for the year.

Data are presented to show the results of medical examination of food handlers under the provisions of the local ordinance.

While the value of this work from the point of view of actually preventing infection from foodstuffs may be questioned, there can be no doubt that the discovery of these chronic defects is of the greatest value to the individual concerned, and the elimination of those suffering with skin infections of any kind is certainly a sound hygienic and esthetic requirement. The fact that for the first time no skin infection or syphilis was discovered during the year would seem to indicate that such persons, knowing the requirements in this city, no longer apply for employment here, or that the employers themselves are more particular whom they engage.

Baltimore, Md.—This city reports a population in 1928 of 830,370, a birth rate of 19.06, and a death rate of 14.36. Extensive statistical tables indicate the trends of disease for the past 9 years. The Bureau of Communicable Diseases reports special work in culturing convalescent cases of scarlet fever with a view to lessening the quarantine period, but thus far it is the impression that the present period of 21 days cannot be shortened. Special culture methods devised for whooping cough cases are considered of some value both in the diagnosis of and release from quarantine of cases of whooping cough. A large number of examinations of urine and feces, mainly of food handlers, has resulted in

the detection of some typhoid and paratyphoid carriers and their elimination as food handlers.

Two interesting outbreaks of food poisoning are reported, one traced to chicken salad and affecting 27 out of 29 persons, characterized by violence of onset and great prostration of the victims; the other traced to chicken patties served at a church supper, affecting 140 persons and characterized by cramps and diarrhea, without prostration. In both cases organisms of the *Salmonella* group were isolated. In both cases the chicken had been cooked at least one day before serving and had been kept without proper refrigeration or adequate protection from contamination.

The outstanding epidemiological occurrence during the year was a wave of poliomyelitis representing the greatest incidence since 1916, a total of 126 cases being reported. There was an early seasonal incidence, with an abrupt decline about September 1, and a low fatality rate. Investigations showed that more than half of the cases received hospital care; 83 cases received serum; of 49 cases given serum before paralysis, 94 per cent entirely recovered; by February 1929, more than half of all the cases had entirely recovered.

This report of 276 pages contains a table of contents at the front and an alphabetical index at the back. It is well printed and carefully prepared.

NEWS FROM THE FIELD

RABIES

SHIRLEY W. Wynne, M.D., Health Commissioner of New York, N. Y., warned the people recently that a bite is not necessary in order for a dog to transmit rabies. The germ is carried in the saliva, and if a person touches the saliva of a rabid dog, he is exposed to the disease.

Dr. Wynne also asserted that it is a mistake to kill all dogs suspected of having rabies. " The animal should be isolated and observed. If he lives a week, it is a certain indication that he is not rabid."

CHILD HYGIENE IN MEXICO

FOR the purpose of combating infant mortality, which in Mexico City is 280 deaths per 1,000 live births, and is even higher in other parts of the country, the federal government issued a decree on May 10, 1929, establishing a Bureau of Child Hygiene (Servicio de Higiene Infantil) in the Federal Department of Public Health.

NATIONAL SCHOOL OF PUERICULTURE

IN Mexico City, a " national school of puericulture " is to be established for teaching care of the child to graduate physicians, medical students, and laymen. Special courses are also to be given for public health officers, employees of the child-hygiene clinic, and visiting nurses.

MILBANK MEMORIAL FUND AIDS EAST HARLEM HEALTH CENTER

THE Milbank Memorial Fund has donated $50,000 to the East Harlem Health Center toward the new 16-story health center, combining an apartment house with completely equipped clinics. This building has been planned by the health center.

OHIO HEALTH COMMISSIONERS

THE Tenth Annual Conference of the Ohio Health Commissioners and the Fourth Annual Meeting of the Ohio Society of Sanitarians will be held at the Neil House, Columbus, O., on November 19 to 22 inclusive. The program of the Ohio Society of Sanitarians has tentatively been allotted to Wednesday afternoon and evening, November 20, and Thursday morning, November 21.

MEASURES AGAINST ILLITERACY IN CHILE

THE President of Chile in his message to Congress of May 21, 1929, discussed, among other things, illiteracy in that country. He spoke of his intention to present to Congress a bill aiming to reduce illiteracy and urged the citizens, particularly employers, to do their share in the promotion of primary education.

In the last year 100 million pesos were appropriated for primary education, and a contract was made with a United States firm for the construction or repair of nearly 600 schools within a period of 5 years.

WORLD MEDICAL CONGRESS

THE thirteenth triennial meeting of the International Physiological Congress took place in Cambridge, Mass., August 19 to 23.

Delegates numbering more than 1,000, from every quarter of the civilized world, were in attendance. Prof. William H. Howell of the Johns Hopkins University was the president of the congress.

This was the first time this group has met in the United States, and it was officially the guest of the American Physiological Society and the Federation of American Societies for Experimental Biology.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF BLINDNESS ORGANIZED

WORD has been received from Scheveningen, Holland, of the formation of an international association for the prevention of blindness, following the meetings of the International Ophthalmological Congress. The League of Red Cross Societies recently made public the report of a 2-years' study of the prevalence of blindness and the principal causes for loss of vision throughout the world, which was made in coöperation with the National Society for the Prevention of Blindness. This was largely instrumental in the formation of the international association.

PERSONALS

DR. THOMAS O. LUCKETT has been appointed Health Officer of El Centro, Calif., to succeed Dr. F. A. Burger.

DR. MAY I. MILLBROOK, of Biwabik, Minn., has been appointed medical adviser to women at the University of Illinois.

DR. JAMES N. BUCHANAN has been appointed Health Officer of Freeport, Ill. He succeeds Dr. Elmer H. Best, who died recently.

DR. GEORGE D. HEATH, JR., who was Health Commissioner of Bloomington, Ill., has been appointed Health Commissioner of Florence, S. C., which position was left open through the death of Dr. Percy H. Brigham.

DR. HAROLD HERMAN ASH, of Reynolds, Ind., is the new Health Officer of White County, Ind.

DR. ENRIQUE HUG has been elected professor of pharmacology in the Faculty of Medicine of Littoral, which is a branch of the faculty of Rosario, Buenos Aires.

DR. FRED BIRD, Melbourne, Australia, died on May 29. He was a prominent surgeon of Melbourne.

DR. MELVILLE G. DANSKIN, Glendive, Mont., was elected president of the Montana Public Health Association on July 16.

DR. LEON BANOV, of Charleston, S. C., has been elected president of the South Carolina Public Health Association.

DR. JOHN FERGUSON of Toronto, Canada, was elected president of the Ontario Medical Association.

DR. CHARLES J. C. O. HASTINGS has resigned as Medical Officer of Health of Toronto, Canada. Dr. Hastings has served for 19 years.

CONFERENCES

Oct. 7–9, International Assn. of Dairy and Milk Inspectors, Memphis, Tenn.

Oct. 14–18, American College of Surgeons, Chicago, Ill.

Oct. 21–23, Missouri Water and Sewerage Conference, Chillicothe, Mo.

Oct. 21–25, Inter-State Postgraduate Medical Association of North America, Detroit, Mich.

Oct. 22–24, New York State Nurses' Association, Buffalo, N. Y.

Oct. 24–26, International Association of Milk Dealers, Toronto, Can.

Nov. 4–7, 8th Annual Meeting of the American College of Therapy, Chicago, Ill.

Nov. 11–13, National Society for the Prevention of Blindness, St. Louis, Mo.

Nov. 20–22, Southern Medical Association, Miami, Fla.

Dec. 3–5, 7th Texas Sanitary Short School, Edinburg, Tex.

Dec. 6–7, New Jersey Public Health and Sanitary Association, Asbury Park, N. J.

Dec. 25–Jan. 1, Society of American Bacteriologists, Ames, Ia.

Public Health Control*

GEORGE W. FULLER, FELLOW A. P. H. A.

Consulting Engineer, New York, N. Y.

PROGRESS in the public health field during the life of this Association has been enormous. The results are not due solely to any one group of workers—professional, technical or administrative—but have been accomplished by activities in many channels. During the past 40 to 50 years, we have played a prominent part in extending the average length of life of the American people from about 40 to 58 years. This result applies to the expectancy at birth, but is due principally to the salvage of the younger age groups rather than to the extension of the age span of the older age groups.

While racial and other factors are important in our present death rates it is certain that there is much work yet to be done in this country, since in Australia and the Scandinavian countries, expectancy at birth has become about 65 years. It is also highly significant that in the United States alone there are 750,000 lives lost annually due to preventable disease and 25,000,000 persons who are below par physically. It is hardly believable that nearly 2,500,000 persons are constantly sick and that 300,000,000 days of work are lost annually due to illness, with terrific monetary losses—directly due to the cost of medical care, and indirectly to loss of employment.

Generally speaking, the American people no longer live in dread of Asiatic cholera, plague, yellow fever, virulent smallpox or pernicious malaria. There has been a profound lessening of the deaths from typhoid fever, diarrhea and other diseases known to be water-borne, due to the team work of public health workers, physicians and engineers. During the past generation experiences indicate that under highly efficient control certain diseases will show greatly reduced

* Address of the President of the American Public Health Association, presented at the Fifty-eighth Annual Meeting at Minneapolis, Minn., September 30, 1929.

death rates. Typhoid fever and diarrheal diseases have been reduced to minor importance in progressive communities. The occurrence of a typhoid fever epidemic is now regarded as a revelation of community negligence. The communicable diseases generally are fast giving way before the offensive waged by preventive medicine—tuberculosis and diphtheria notably. Smallpox is practically nonexistent where vaccination is properly practiced. Where communities apply themselves properly to the problem, deaths from childbirth show a signal reduction.

The degree of reduction of morbidity and mortality has varied, of course, for different diseases and in different sections of the country. Also the conditions in some parts of the United States are so excellent that they atone statistically for the terribly high infant and general morbidity and mortality rates in certain communities.

We have much to celebrate in public health achievement. However, constructive action and future progress result not from reminiscing about the past and singing praise to our predecessors who richly deserve tribute, but rather from emphasizing our hopes and presenting our plans for achieving still greater benefits for the public welfare in the future.

Frequently it has been customary to deal in presidential addresses with some theme of technical interest, which the speaker has forborne doing in this instance. It seems of greater practical value to the organization to do a bit of accounting in a generous but searching and analytical spirit, and to ask how we stand as to carrying on the objective of the Association—which is to protect and promote public and personal health.

Public health control deals with the organized effort to eliminate disease, to elevate standards of health, and to increase the span of life. It is the application of sanitation and hygiene to individuals en masse. Public health activities have three main phases: First, the basic principles or theory upon which practice is founded; second, the administration and enforcement by health officials of the statute laws emanating from the principles of hygiene and sanitation; and finally, the development of an intelligent public opinion in order to secure legislative and financial support for health administration and research. In summary, therefore, public health control comprises technical knowledge, administrative practice, and public education.

Slow progress in the past was due in part to too much attention having been given to details representing the views of one person or another temporarily in a position of authority. Too little attention has been given to sound principles of organization and to sustained

continuity in the development of a broad program of procedure representing group judgment. The aim of this address is to suggest ways in which public health control may be advanced more rapidly.

RÔLE OF A. P. H. A.

For 58 years the American Public Health Association has been the leading professional organization of the North American continent for the formulation of procedures intended to improve public health control. It is not an official organization of administrative health officers but a professional society, which counts among its membership the leading health administrators of this continent. Its ten sections conduct important meetings annually for the improvement of the technical foundations upon which sound public health practice is based. It is true that there are other national organizations contributing to the broad field of public health; but only in the American Public Health Association have those specialties been developed and tested for nearly three score years and been made to bear on public health administration.

This Association is built on a tradition of service which has made it for the past 58 years the rallying place of public health administrators. Others may be interested in public health from many angles, but this Association seeks particularly to serve the administrator to the end that public welfare may be enhanced; that morbidity and mortality may be reduced, not by rhetorical phrases but by study and counsel as to the best technical methods. This leads naturally to the consideration of a function not uniformly well achieved, namely, standardization when periods of experimentation are at an end. Research to formulate standards in every branch that is collateral to public health service is peculiarly the objective of this Association. Whether it relates to the work of the statistician and the service he may render, the engineer, the nurse, the public health educator, the physician skilled in communicable disease control, the health battalions who watch over the health of school children, the industrial hygienists, or any other group—ours is the particular and peculiar business to advise specific methods of attack. We are an international board of strategy in health matters. Obviously it follows from this that the health officer must transmit and put into effect the theories and the principles of action that are discussed and given validity in this international clearing house.

It follows then that such a body as this should take cognizance of every problem of current interest. As these questions arise, we need effective machinery to interpret, with sound judgment, the specialized

knowledge of health administrators and educators of the North American continent, so that teachers, leading citizens, legislators, and the public at large may be informed and helped to a better understanding. We must have machinery to make vocal our ideas and our ideals.

Complexity of membership and of the interests involved in the A. P. H. A. does not lessen the responsibility of all concerned, to provide the opportunity for health officers to make this Association serve adequately as their professional society. Whether or not they take advantage of such an opportunity rests largely with them. Although the A. P. H. A. should be the rallying point for these sanitarians, it must be clearly borne in mind that it is a going concern with considerable strength as an association of the health officers' coworkers. It includes, in its sections, large numbers of those technically trained individuals who provide the scientific support for the health officers' work, to say nothing of the public health nurse.

At this point differentiation should be made between the professional administrative worker and the professional technical worker. The latter devotes his efforts to improvements in the scientific foundations of public health practice and to the diagnoses of results. To my mind, these technical workers, including engineers, laboratory men, statisticians, and others who constitute the respective sections of this Association, are not professional workers in the sense in which that term is used by some. They are primarily technicians engaged professionally in technical or scientific vocations.

They are not professional workers in the public health field in the sense of having authority to carry out administrative measures founded upon the police powers of the State, or being held responsible for the securing or disbursement of funds, control of personnel, or the establishment of rules or regulations. Yet, while appearing as subordinate, they play a vital part in the teamwork that is implied in the term public health administration.

The administrator must lean heavily upon his technical coworkers for the accuracy of his prescriptions—prescriptions which deal with problems of ventilation, sewage disposal, water supply, milk supply, and dairy products generally; problems of hygiene of the infant, the mother, the school child and the industrial worker; problems of statistics, education, and a host of other problems of daily or emergency occurrence. What is more logical than that there be a close merger between the technicians and those who must give effect and force to their prescriptions, through an Association such as this?

Looking now at the American Public Health Association in the light of the three principal lines of activity in the public health field,

we find that it is comparatively weak as a professional society of official health administrators; relatively strong as an association of technical health workers; and practically inactive as a force in molding public opinion, although we have a section well informed as to educational methods. The organization is capable of making still greater progress; but the set-up of the Association is such that it needs more clearly defined allocation of authority, and executive responsibility.

NEED FOR REORGANIZATION OF THE A. P. H. A.

Having tried to view the functions of the Association in proper perspective, I have felt that it was incumbent upon me during the year of my official service as the head of this organization to consider whether we were as adequately prepared to achieve our objectives, in the light of recent progress and development, as is necessary. In giving an accounting of my stewardship, I desire to inscribe in the history of the Association a record of reappraisal and of reconstruction where necessary.

An effort has been made to visualize a central organization that would better integrate the efforts of the technicians and professional men scattered over this vast expanse of territory from which we draw our membership. The details have been presented in the form of proposed amendments to the Constitution and By-laws, but little can you imagine the efforts that have been required to study these needs in a dispassionate way in order that the central organization may be made to be a still more effective clearing house of official public health work in America, and to serve better those whom it is intended to serve.

RESEARCH AND STANDARDS

Public health progress has been and will continue to be dependent in part on advancement in our knowledge of technical procedure. This in turn involves research and study, in an unbiased way, of statistical data and the results of research, so that after suitable discussion and publicity the promulgation of unified practice and so-called standards—at least tentative standards—may be forthcoming. Through the aid of the committees and sections of this Association, scientific progress is made more effectively than would be possible through the individual efforts of detached workers, regardless of their skill or the comprehensiveness of their performance. The open forum does a world of good even among scientists in separating the wheat from the chaff. To be effective, the discussion and coöperative actions of these individuals, however, need thorough organization.

In many associations there has been a tendency to take up a problem and proceed precipitously in the direction in which it is hoped to

find its solution. Suitable consideration is not given to the scope of the undertaking, either with reference to the adequacy of investigation, or the unbiased discussion of results. Naturally, the conclusiveness of the outcome is more or less jeopardized, and the securing of funds for a definite undertaking is made more difficult.

In advancing scientific knowledge in the field of public health, it is necessary, first, to take some of the more important of the proposed problems and develop them into what the business man calls a definite project. By that is meant that a reasonable inquiry should be made into the available evidence with respect to the given problem. Then ample study should be given to developing a program which comprehensively deals with the scope of the proposed undertaking. The personnel, time and funds needed should be carefully estimated; the prospects as to what advantages may be expected from the results should be weighed; and, finally, decision should be made as to whether such a comprehensive program is worth while. If it is worth while, the program for the development of the problem into a project should be reviewed, criticised, and decided upon in such a way that the enterprise may be sold to those who are in a position to contribute funds for its support. This necessity for translating problems into worthwhile projects, in order to secure financial support, is not always recognized.

There is no reason why financial support from industry should not be secured and accepted for research and standardization activities by the American Public Health Association; provided always that the proposed problems are adequately developed into meritorious projects, and carried out free from any bias in favor of the industry contributing funds. However much we may need the sinews of war to carry on research and standardization efforts we cannot place ourselves in a position which would compromise our dignity or reflect upon our dispassionate and scientific interest in public health.

Progress at a more rapid rate may be made in matters of research and standards if the American Public Health Association organizes more efficiently. Indirectly such advances should be of benefit to the Association in the third aspect of public health control, namely, public health education.

EDUCATION OF THE PUBLIC IN HEALTH MATTERS

The American Public Health Association has not progressed very far in educating the public in matters of personal hygiene, in supporting adequate legislation, or in improving salaries or tenure of office of health officers.

Its efforts to reach laymen who have a real interest in public health and other welfare undertakings have not been conspicuously successful, if we except the work of the Committee on Administrative Practice, with its recent contacts with Chambers of Commerce and the lectures on the Chautauqua platforms which the A. P. H. A. has directed through arrangements made possible by the Milbank Memorial Fund. The Association's progress, in a coöperative educational way, in affiliated state and regional societies has necessarily been slow.

Progress by voluntary health agencies as a whole, in the view of some, has been retarded by overlapping, uneconomical and uncoordinated efforts, particularly in the field of public health education. Too much attention by far has been given to details, and not enough to guiding principles of action. Efforts have been made to do too much at a time. So much attention has been given to examination of leaves and the characteristics of a few trees, that the relation of the forest to the whole landscape has not been clearly visualized.

It would probably be wise to place on the health officers of the A. P. H. A. the initial responsibility of selecting two or three aspects of public health which might reasonably be made the basis of effective education of the public. It would probably be feasible for the A. P. H. A. to invite other health agencies to attend a conference to adopt, in principle, initial steps necessary for increasing the knowledge of the public in specific phases of public health work. If a suitable topic is selected, support of the conference could presumably be obtained for the appointment of a steering committee to develop an appropriate program of action which in time could be translated into an effective project.

It is unwise to attempt to get any wholesale amalgamation of various voluntary agencies. Let each continue to function as effectively as it can. But it would seem feasible to do constructive, coöperative work through the federation type of organization. Several federations—which need not be permanent—could be developed, each to carry out a specific project. One federation might be formed, for instance, to secure wide popular interest in periodic health examination. When that campaign had been reasonably successful, that federation could be dissolved. A second federation dealing with another item might have substantial differences in personnel and sources of financial support. Three or four such federations might be in existence at the same time, each tackling one problem, through coöperative and coordinated work, developed in accordance with sound principles. Such programs along federated or coöperative lines could apparently get financial support. Such beginnings, even in a modest way, would

engender progressively mutual understanding and confidence among the numerous agencies now in the field, and in such a general movement the A. P. H. A. could render real service if it would participate in the initiation of such a program.

POPULAR HEALTH JOURNAL

There is not now being widely distributed to the people of the North American continent authentic information in simple language which would create a harmonious viewpoint on matters of individual and community health. The material at present is technical and smacks of propaganda. Competition among unofficial and professional agencies causes unbalanced and even conflicting reactions on the public.

There is a real demand for a popular priced monthly health magazine, sold on the news-stands. It need not conflict with existing journals. With its management organized along effective lines, embodying principles of federation as above set forth, financial support could doubtless be secured for such a journal for the necessary initial period. The undertaking should be self-supporting in a few years. With expert management, a low subscription rate, and the coöperation of industry, a large circulation should be possible which would attract advertising at high rates.

In the development of such a program, as outlined, the American Public Health Association can serve as a nucleus for a coöperative and coördinated plan.

RELATION TO ORGANIZED MEDICINE

The medical profession plays an important part in matters of the health of the individual, but probably more so in curative than in preventive medicine. Modern medical training is slowly changing this view, and ultimately the community aspects of health work will appear more important than is now the case with many of the older members of the profession. In the meantime, differences of opinion and lack of mutual understanding are unfortunately apparent. It is gratifying to note that the A. P. H. A. is establishing committees to deal with this particularly important phase of future public health activity.

It will be wise for public health agencies of all types to take the medical profession into their confidence, to encourage the teaching of the principles of public health in medical schools, and to interfere as little as practicable with the private practitioner, in carrying forward modern public health work. Physicians have had some cause for fault

finding in the past, and it is to be hoped that a spirit of friendly and effective coöperation, as well as a program of mutual benefit, may ultimately result from discussion. This cannot be done on any wholesale basis; but conferences of fair minded representatives can progressively take up one phase at a time, and arrive at mutually satisfactory conclusions. Surely it is to the advantage of no one to have such antagonisms continue. The A. P. H. A. should be able to create gradually a better understanding between the practicing physicians and those related to their work from the standpoint of public health control.

SUMMARY

This address is intended to emphasize the need for setting up principles of procedure for a more efficient control of public health activities, particularly as these relate to service rendered to health officers and others of the A. P. H. A. The principal items stressed are as follows:

1. Reorganize the A. P. H. A. to bring about stabilization of administration; clarification of the authority and the allocation of responsibility of its officers; and the establishment of better methods of financing and program making; with the continuance of the excellent work of the Committee on Administrative Practice.

2. Lessen the overlapping of efforts by voluntary health agencies, by securing support for specific undertakings recommended by the health officers' group.

3. Provide an effective and scientific organ with popular appeal for expression on problems of today that affect public health.

4. Endeavor to promote better relations between medical practitioners and public health workers.

5. Strengthen the position of the A. P. H. A. in matters of research and standards and, after giving due consideration to various problems, concentrate upon the most timely and necessary ones, with a view to developing them into specific projects. Secure more adequate financial support for such undertakings from sources that will not compromise our independence, self-respect or dignity.

6. Put the responsibility on the administrative health officers for strengthening their strictly professional activities in this Association, giving them ample opportunity to develop and exercise leadership in the affairs of A. P. H. A.; for concentrating on topics that are most helpful and valuable to them and to their communities; and then expect of them the full discharge of their responsibilities.

The Sewage Disposal Problem of Minneapolis and St. Paul*

J. A. CHILDS

Chief Engineer and Secretary, Metropolitan Drainage Commission, St. Paul, Minn.

IN order to understand clearly the sewage disposal problem which now confronts the Twin Cities it is necessary to know something of the history of the Mississippi River, as well as its physical condition, and to see how changes wrought by man have affected this problem.

The Mississippi River has its source in the numerous lakes in northern Minnesota. It flows in a southerly direction a distance of nearly 2,500 miles to the Gulf of Mexico and it has a total drainage area of nearly 1,240,000 square miles.

Since the first settlers entered the country, the river has been a very faithful servant. It was the first trade artery for the early traders and trappers. For many years steamboats on the river carried considerable commerce and made possible the early settlement of the Northwest. The river also has been used extensively as a means of cheap transportation of logs to the saw mills, and at one time supported extensive and profitable clamming industries. Many of the early settlements including Minneapolis and St. Paul owed their existence to the river and the facilities afforded by it. Though to a large extent that faster means of conveyance, the railroad, has taken the place of the river as a means of transportation, the river has been put to work in other ways. It now furnishes a great amount of power for domestic and industrial uses, and is the principal source of water supply for both Minneapolis and St. Paul as well as for about 20 municipalities in Iowa, Illinois, and Missouri. The river has received for many years, and is now receiving—for the most part in an untreated state—the sewage and industrial wastes of the cities along its course.

Before the advent of the white man the 500-mile stretch of river from its source to St. Paul was for the most part a rapidly flowing stream with a total drop of about 750 feet. The 100-mile stretch

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

above Minneapolis has an average fall of over 3 feet per mile. The construction of power dams has changed a portion of this stretch from a rapidly flowing stream to a series of quiescent pools, altering the natural conditions, particularly as regards ice coverage and surface aeration.

RIVER FLUCTUATIONS AND OXYGEN CONTENT

The ability of a river to receive and assimilate waste matter satisfactorily is dependent upon several important factors, among which are volume of flow, and the dissolved oxygen content. The discharge of the Mississippi fluctuates widely, the recorded average monthly flows at St. Paul ranging from 1,300 cubic feet to nearly 60,000 cubic feet per second. The dissolved oxygen content of the river entering Minneapolis also ranges from about 6 to nearly 14 p.p.m. The period of minimum oxygen content (about 6 p.p.m.) occurs twice a year, usually in February and in July. The low oxygen content in winter is caused by ice coverage which prevents surface aeration; the low oxygen content in midsummer is largely the result of decomposition of organic material which takes place more rapidly at higher temperatures. When the time of minimum dissolved oxygen content coincides with a low river discharge, which is often true, a critical condition is created.

Thus there are likely to be two critical periods, one occurring during the latter part of the winter, the other in midsummer, both of which must be considered in determining the degree of sewage treatment necessary. It is during the critical winter period that fish life in Lake Pepin, about 45 miles below St. Paul, is most seriously affected. It is during the critical summer season that nuisances are most likely to exist.

TWIN CITY LOCK AND DAM

A dam known as the Twin City Lock and Dam was constructed in the river between Minneapolis and St. Paul in 1917. This dam is about 33 feet in height, and has formed a pool of relatively quiet water about 5 miles in length, extending up stream to the Washington Avenue bridge in Minneapolis. All but one of the sewers of Minneapolis, and several of those of St. Paul discharge into the river above the dam.

Prior to the construction of the Twin City Lock and Dam in 1917, the sewage was swept away by the rapid current, so that the effect of pollution was not particularly apparent in the immediate vicinity of the Twin Cities. The construction of this dam has, however, so retarded the current of the river as to permit the deposit of large quantities of sludge on its bed in the pool above the dam. Soundings

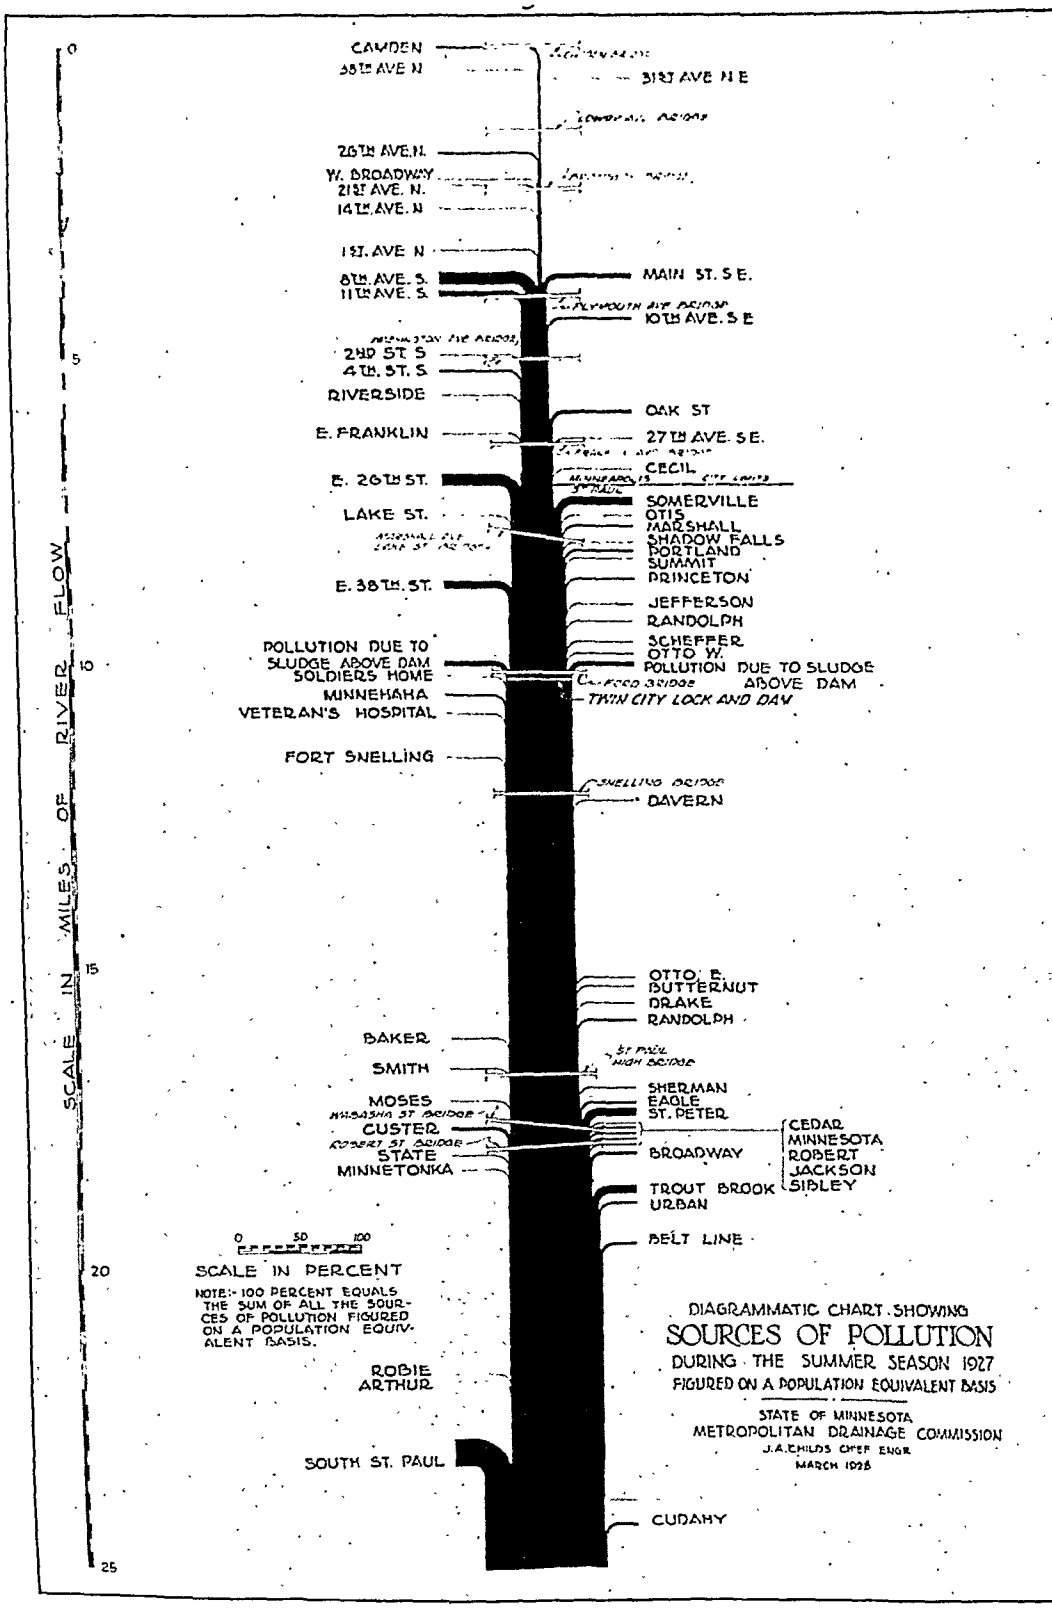

FIGURE I—Sources of Pollution Entering River. Each horizontal line represents a sewer outlet, the weight of the line indicating the per cent of the total pollution in terms of population equivalent contributed by that particular outlet. The width of the vertical line at any point is proportional to the total amount of pollution entering the river in this area above that point.

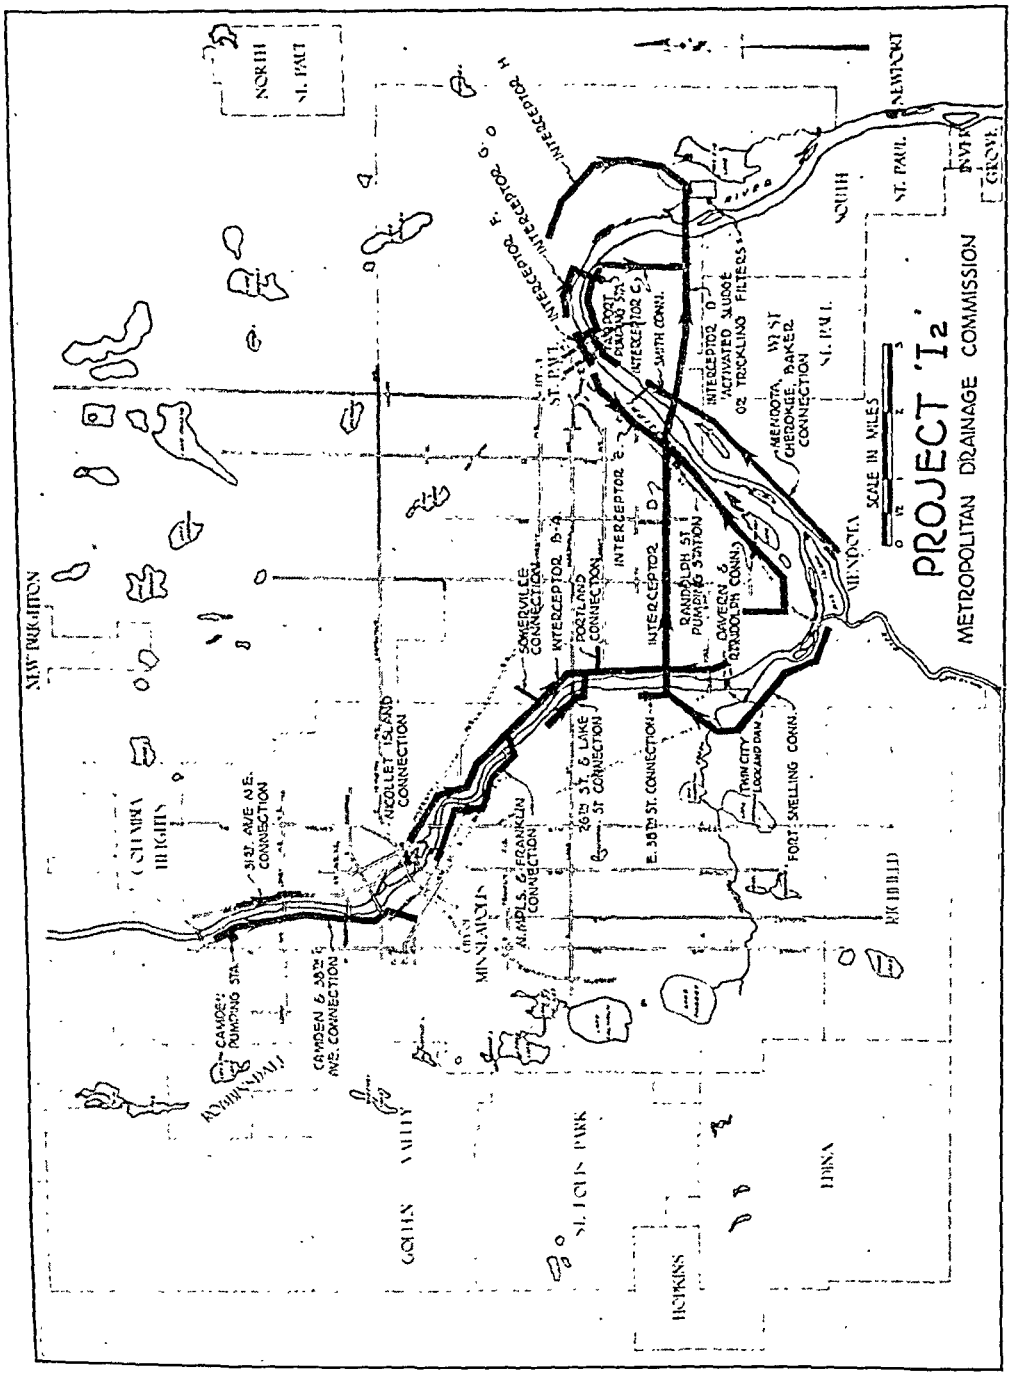
made in 1928 indicated that about 3,000,000 cubic yards of sludge and silt have been deposited in this pool. The sludge which is deposited during the winter decomposes very slowly until early summer when the higher temperatures stimulate active decomposition as evidenced by rising gas bubbles, odors, and floating masses of sludge.

THE HASTINGS DAM

A new dam is being constructed below St. Paul at Hastings. This dam will create a second pool of relatively quiet water about 30 miles in length extending upstream to the Twin City Lock and Dam. Into this pool will be discharged a large part of the sewage from St. Paul, and all of the packing plant wastes from South St. Paul and Newport. Though the total present sewered population in the Metropolitan Area was estimated in 1927 to have been about 685,000, the industrial wastes have so increased the pollution that its effect was that of the domestic sewage from a population of nearly double that amount, or about 1,300,000. Such, then, is a general survey of the problem confronting the Twin Cities.

SANITARY SURVEY BY U. S. PUBLIC HEALTH SERVICE



The first official notice of this polluted condition was contained in letters to the city councils of Minneapolis and St. Paul from A. J. Chesley, M.D., Executive Officer of the Minnesota State Board of Health, in July, 1923. Through the interest and financial assistance of the cities of Minneapolis and St. Paul, the Minnesota Commissioner of Game and Fish, the Minnesota Department of Health, and of the Wisconsin Conservation Commission, sufficient funds were raised so that an investigation of the pollution of the river could be undertaken. This investigation was begun in June, 1926, and continued until September, 1927, under the direction of H. R. Crohurst, Sanitary Engineer of the U. S. Public Health Service.

METROPOLITAN DRAINAGE COMMISSION

The act creating the present Metropolitan Drainage Commission was passed by the 1927 legislature. The commission was organized and work actually begun in October of that year and has continued to the present time.

The Commission has received the most hearty coöperation of the Minnesota Department of Health, particularly in connection with the continuation of the stream pollution studies begun by the U. S. Public Health Service.

Among the various phases of the problem studied by the commission are: population, areas, water supplies, existing sewerage sys-

tems, sewage quantities, sewage characteristics, industrial wastes, extent of treatment required, suitability of plant sites, projects, costs, and construction programs. A statement of the findings of the commission is contained in its 1928 report. Space permits only the briefest summary.

Population—A population census was estimated by sewer districts. This census indicated a total population in 1927 of about 775,000 in the area, of which about 720,000 live within the corporate limits of Minneapolis and St. Paul, and about 685,000 in areas provided with sewers. It is estimated that the population of this area will be about 1,450,000 by the year 1970.

Area—Of about 65,000 acres within the present corporate limits of Minneapolis and St. Paul not including parks and play grounds, about 40,000 acres, or 62.5 per cent, are sewered. It is estimated that a total of about 94,000 acres will be sewered by 1970. It is interesting to note that the population density is at present rather low when compared with many cities, that in Minneapolis being 14.2 per acre and in St. Paul 8.4 per acre.

Water Supplies—These studies included quantities from both public and private sources; hourly, daily, and seasonal fluctuations; and an analysis of the quantities used for domestic, and for commercial and industrial purposes. The total daily consumption was found to be about 100,000,000 gallons.

The Sewerage Systems—The systems of Minneapolis and St. Paul are, with few exceptions, of the combined type, comprising in 1927 a total of over 1,100 miles of pipe. Including the private sewers of the packing plants at South St. Paul and Newport, there is a total of 80 major outlets.

Sewage Quantities—During the winter of 1927 and 1928 weir measurements of sewage flow were made on practically all of the sewer outlets of Minneapolis and St. Paul, South St. Paul, and Newport. The measurements were made at hourly intervals. The total dry weather discharge sewage including waste and ground water was estimated to be about 110 m.g.d.

Sewage Characteristics—Samples of sewage were collected hourly at the same time that the weir gauges were read. Composite 24-hour samples were made from the hourly samples in proportion to the flow at the time of collection. Thus each composite sample represented an average of the entire flow of sewage from the 24-hour period. These samples were subjected to routine laboratory tests such as, the 5-day biochemical oxygen demand, suspended matter, pH values, temperature, and bacteriological examination.

The population equivalents computed from the sewage quantities and the oxygen demand data have been tabulated in such a way that these population equivalents could be compared with the estimated sewered population of the districts. Only a few of the districts may be said to be reasonably free from industries. In most of these districts the population equivalent as calculated from the analytical data was found to be nearly the same as the estimated sewered population. The population equivalent exceeds in many instances the estimated population of the district, because of presence of industrial wastes.

The cumulative pollution is shown in graphic form by Figure I in which each horizontal line represents a sewer outlet, the width of the line representing the proportionate pollution in population equivalent contributed by the sewer outlet which it represents.

Extent of Treatment Required—As previously stated, there are two critical periods which must be considered. It is estimated that complete treatment of the sewage will not be required even by 1970, although treatment somewhat in addition to that effected by clarification will probably be necessary at an early date. The first and most essential step is the construction of intercepting sewers and settling tanks by means of which the major portion of the sewage can be collected and treated by sedimentation. This simple treatment will to a large extent prevent the formation of sludge deposits and will go a long way toward producing the desired results.

PROJECTS

Over twenty projects have been studied and compared. One of the desirable projects is known as I_2, Figure II, which provides for the collection and removal of the sewage from both cities to the Pig's Eye Lake district for treatment and disposal. Though costing more to construct than some of the others, this one will effect the most thorough cleaning up of the river pollution through the Twin Cities, and will place the treatment plant on a large tract of relatively isolated land where ample area for expansion is available.

The cost estimates indicate that about 85 per cent of the sewage of the Twin Cities can be collected and subjected to a clarifying process for an initial construction cost of about $12,000,000 if project I–2 is adopted. No final decision relative to a secondary treatment has been made at this time, although both the activated sludge and trickling filter processes are being considered.

DISCUSSION

C. F. KEYES

Chairman, Metropolitan Drainage Commission, Minneapolis, Minn.

THE outline of the technical phases of the problem confronting the Twin Cities as presented by Mr. Childs is only one phase. The Metropolitan Drainage Commission was created for the purpose of studying this sewage disposal situation, and of reporting how it might best be handled. The commission is simply a study organization without authority to let contracts or do construction work.

Lying immediately outside the corporate limits of Minneapolis and St. Paul are several smaller cities and villages, some of which already have sewerage systems discharging into and using the sewers of Minneapolis and St. Paul as a means of disposing of their sewage and wastes. It is obvious that any scheme which might be adopted should be comprehensive enough to serve the future needs of these outlying municipalities as well as those of Minneapolis and St. Paul. The area actually studied by the commission includes 17 smaller villages and cities and 9 townships located in 5 counties, with a gross acreage about double that of the present area of the Twin Cities.

To the south of St. Paul are the municipalities of South St. Paul and Newport in which large packing plants are located. These packing industries contribute about one-tenth of the total volume of sewage and waste from the entire area, and because this waste is strong, it constitutes about one-fourth of the total pollution. The river cannot be restored to a satisfactory condition without reducing the polluting effect of this waste. This waste may be treated separately or included with the sewage from the Twin Cities. A decision as to ultimate disposal of this waste is not required at this time, since no change in the design of the main intercepting sewers would be required if this waste should later be included with the sewage from the Twin Cities.

It seems advisable for many reasons that Minneapolis and St. Paul should unite for the purpose of carrying out a unified program of sewage disposal. Although public sentiment is generally agreed as to the necessity of providing some immediate means of collecting and treating the sewage wastes of the district, differences of opinion have arisen as to the area which should be included in the district; the methods of financing; the apportionment of costs; and the constitution of the governing body to administer the affairs of the district.

After a study of the problem covering more than a year's time, the Metropolitan Drainage Commission came to the conclusion that the most feasible, practicable, and economical method to relieve the local nuisance conditions in the river adjacent to the Twin Cities was to organize a Metropolitan Sanitary District to include the territories of Minneapolis and St. Paul. Such district would constitute a municipal corporation, would be governed by a board of trustees, and would have power to levy taxes, incur indebtedness, and undertake the construction and operation of a sewage disposal system, including intercepting sewers, pumping stations and treatment works. The commission recognized that the organization of such a district would not entirely solve the problem of river pollution in the Twin Cities area, in that it would not take care of the industrial wastes contributed by the packing industries of South St. Paul and Newport; but it was felt that it would be

impracticable at the outset to attempt to include these independent municipalities as an integral part of the district.

A bill was accordingly drafted and introduced in the Minnesota legislature last winter calling for the creation of a Metropolitan Sanitary District as above outlined. This bill contained a carefully worked out plan for apportioning the costs between the cities of Minneapolis and St. Paul on as equitable a basis as possible. In brief, each city was to pay for the intercepting sewers which serve each city separately. Interceptors used jointly by the two cities were to be paid for jointly in proportion to the assessed valuation of the two cities. The cost of treatment works and operation costs were to be apportioned between the cities in accordance with the volume and pollutional content of the sewage contributed by each city. Provision was also made authorizing the Sanitary District to enter into contract with outside municipalities to receive and treat their sewage at cost.

Owing to objections raised to provisions of the bill, it never came to a vote in the legislature. It was the opinion of the St. Paul group that South St. Paul and Newport should be included in the district at the start, and that the entire costs of construction and operation of the sewage disposal system should be distributed over the entire district by uniform tax levy. Inasmuch as the assessed valuation of South St. Paul and Newport is less than 2 per cent of that of the entire area, while the packing industries of these two communities contribute about one-fourth of the total pollution, this would mean that Minneapolis and St. Paul would pay about 98 per cent of the cost of treating the packing plant wastes. This would increase the cost of sewage disposal to the Twin Cities about 20 per cent above what it would be for the treatment of their sewage alone.

While it is true that the packing industries are a benefit to the Twin Cities, especially St. Paul, and to the Northwest, it was the belief of the commission that any method of financing that would compel the cities of Minneapolis and St. Paul to pay practically the entire cost of the packing house wastes could not be justified. The commission further felt that when a Sanitary District for the Twin Cities was in operation, it should be in a position to contract with the packing industries for the treatment of their wastes on a basis that would be fair to these industries without imposing an undue financial burden upon the Twin Cities.

Should the two cities fail to get together on a joint solution of their sewage disposal problem, the only alternative would be for each city to go it alone. This would involve a greater expense to both cities, and would be especially burdensome to St. Paul; for from a financial standpoint St. Paul has more to gain than Minneapolis, if the two cities united for a joint handling and disposal of their sewage wastes, under such a plan as was proposed for the creation of a Metropolitan Sanitary District. In the meantime the commission is continuing its work in order that plans for a project or projects may be advanced as far as possible, and so that there may be no unnecessary delays in beginning construction, irrespective of what plan shall be ultimately adopted to solve the sewage disposal problem of the Twin City area.

The Problem of Sweets for Children*

IN view of the claims now being made in behalf of a larger use of sweets as food, it behooves us to take our bearings anew in the light of all our present-day knowledge of nutrition.

Counting air and water as free, there are five kinds of substances which make up the "food values" which we acquire when we buy food. These are: (1) the proteins, (2) the fats, (3) the carbohydrates, which include the sugars and starches, (4) the mineral elements, and (5) the vitamins.

In general we do not buy these food value substances separately, or as such; we buy *articles of food* such as bread, meat, milk, fruits and vegetables. Such articles as we have just mentioned contain several kinds of substances of food value and so are *many-sided* foods; whereas articles which furnish only one kind of substance of food value, such as some oils and fats and all pure sugars and starches, are *one-sided* foods.

Now a one-sided food is not necessarily to be avoided; but in order that good food habits may be formed and good nutrition insured, we must be careful to keep one-sided foods from encroaching upon the proper place of the many-sided foods—whether in our eating habits or in our food budgets. That is, both in choosing what to eat, and how much of it, as we go along, and in deciding how to divide up the money which we spend for food, we should keep sweets as well as all other one-sided foods quite strictly in their proper place.

That the eating of candy easily lends itself to abuse is a fact which until recently was clearly recognized by nearly everyone. Even those who indulged freely in sweets agreed that it was an indulgence and not an entirely wholesome food habit. But at present there seems to be on foot a concerted attempt to obscure this fact, and not only is the public being "educated" to eat more sweets, but some writers who undoubtedly have ability and influence are advocating the feeding of more sweets to children. Are their arguments sound?

This question gains added significance through the fact that at the very moment this is being written there arrives a newspaper report that, "The International Sugar Experts Commission, now (April 5,

* Report of the Committee on Nutritional Problems, presented to the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

1929) in secret session at Geneva," proposes "the organization of a widespread educational campaign to demonstrate the desirability of more extensive employment of sugar."

To aid us in forming our own judgment as to whether there really is any such "desirability," let us glance briefly at the different types of food materials which make up the bulk of our food budget, and the significance of each to our nutrition.

Breadstuffs and other grain products (rice is to the Oriental what bread is to us) normally make up the largest and cheapest source of calories and of protein. In these two respects they bring us the most food value for the money. But they are not satisfactory sources of the other two great factors in our nutritional need, the mineral elements and the vitamins.

The meat foods ("flesh, fish and fowl") are rich either in protein or fat or both, which together with their flavors and stimulating extractives give them the properties of "satisfying" and of "staying by." These properties make the meat foods popular and account for the fact that they occupy a large place in the food budgets of most people who can afford them (and perhaps also of many people who, properly speaking, cannot). But it is a very important fact, although difficult for many people to accept, that in general (there are a few exceptions in detail) the meat foods show about the same mineral and vitamin deficiencies as do the grains, so that while breads and meats may form pleasing and satisfying combinations, yet *nutritionally* they can never make a properly balanced diet, and least of all for a growing child—even though a hardy explorer may be able to live a long time upon such a diet without showing or feeling any noticeable injury.

Fruits and vegetables vary greatly in their values as sources of proteins and calories, but these two groups of foods may be counted as one in that they are, in general, important sources of some (not all) of the mineral elements and vitamins, of which both the breadstuffs and the meat foods are but poor or uncertain sources. Hence the fruits and vegetables (at least many of them) are entitled to McCollum's designation of "protective foods," since they tend to protect us from the mineral and vitamin deficiencies which we incur if we live too largely upon the breadstuffs and meat foods.

By far the most important of the protective foods is milk, for it is the most efficient (and almost always the most economical) of all foods in making good the mineral and vitamin deficiencies of the breadstuffs and in insuring the all-round adequacy of the dietary. "The dietary should be built around bread and milk," with fruits and vegetables occupying the places of next importance. The milk, vege-

tables and fruits of such a dietary insure good supplies and excellent forms of proteins, mineral elements, and vitamins, while the bread is an economical and wholesome source of the additional calories needed, and of a generous extra allowance of protein for good measure.

Eggs may be said, in general terms, to stand about midway between milk and meat in their nutritional properties. The fact that eggs blend well with many other things, and aid in the attainment of the varied textures desired in cooked foods, gives them a value of their own in cookery and tends to keep them rather expensive for the food value that they furnish, so that in general they are less economical as "protective food" than milk.

Some of the fats are rich sources of fat-soluble vitamins while others are not. The fats as a group constitute a concentrated source of calories (a compact form of fuel for the body); they stay a relatively long time in the stomach, thus delaying the onset of hunger pangs—a property the lack of which in such foods as bread and turnips was found to put a severe strain upon the morale of both soldiers and civilians in Europe during the war; and in addition to their nutritional significance, fats have their special places in the arts of cookery.

What then is the place of the sweets? Like eggs and fats they are esteemed in cookery as means of attaining the flavors and textures desired in many food mixtures and "made dishes"; but we are here chiefly interested in their nutritional significance. Candied fruits, milk chocolate, ice cream, and so on, are sometimes cited as sweets which convey mineral and vitamin values, and this is true to the extent that they contain fruit, milk, or other of the foods which are good sources of mineral elements and vitamins; but the sugar itself contributes nothing to the food value except as a source of calories.

Children normally are active and spend more calories in proportion to their weight than do any but very active adults; but the children are growing at the same time and ought to get liberal supplies of proteins, vitamins, and mineral elements along with their calories, and it is a sobering thought that sugar, as it now comes into commerce, is the most completely devoid of proteins, vitamins, and mineral elements of all the foods which we give our children. From the nutritional standpoint therefore it would seem that sugar should be of all foods the most cautiously used in feeding children, lest it displace too much of the foods which can do what it cannot, in supplying the proteins, vitamins, and mineral elements which children need so urgently and so abundantly for their healthy growth and development.

We sometimes hear of the "natural craving" of children for sweets; but what sweets do we find in nature? Never do we find in

nature either candy or such concentrated and isolated forms of sugar as are found in the grocery and confectioners' shops. In sweet foods as they actually occur in nature, the sweetness is largely a bait which renders more acceptable to the palate the mother's milk, which is undoubtedly the best of all foods for the young, and also the juices of many fruits and vegetables (and even the saps of some trees), which are of added nutritive value to us because of the mineral elements and vitamins which they contain. (If we trace the "natural" function of sweetness still further back we find that the sweet which we meet in honey was before that contained in the nectar of the flower where it served to bait the bee which, in collecting the nectar for his own use, spreads the pollen which serves to reproduce the flowering plant.) Thus sugar is essentially a bait, or in Bunge's words, "not only an aliment but also a condiment, and easily lends itself, as all such things do, to abuse."

The danger of abuse is of more than one kind. Too much sugar may spoil the appetite for other foods of less pronounced flavor but much more pronounced value in nutrition, and it may displace these more important foods in meeting the calorie needs of the body with the result that while the calorie need is fully met there may be a shortage of some essential mineral element or vitamin; a shortage not detected at the time but detrimental to subsequent growth and health.

It is argued that sugar is good for active children because it is a "quick fuel," and the use of sugar by athletes during endurance contests is cited in support of this idea. The idea has some basis, but it is greatly overworked, if not actually perverted. Who would seriously consider a Marathon race as a suitable exercise for a growing child? And who would seriously claim that the concentration of sugar which can be borne by the fully developed and hardy stomach of an athlete would be equally well suited to the still developing stomach of the growing child which always has enough to do to handle the large amount of food which growth requires, without subjecting it to any unnecessary risk of irritation?

Careful study of much that has recently been written in behalf of increased use of such concentrated sweets as candy leaves us with the distinct conviction that such teaching is not sound from the standpoint of the health interests of children.

In our judgment, it is just as true today as it has been for several years past, that the practical lesson to be learned from the newer knowledge of nutrition is the great importance to health (at all ages and especially in childhood) of giving a more prominent place, in our eating habits and in our food budgets, to what McCollum has called

"the protective foods," i.e., to milk, fruit, and some of the vegetables; and that a "more tolerant" attitude toward sweets for children is not justified except in so far as the use of sugar and other sweets may be practically helpful in preserving the protective foods or facilitating their attractive preparation so that children may be induced to live more largely upon them.

A moderate amount of jam may be good for children—its sweetness may appeal to their palates and its fruit content will almost certainly be good for their health. A liberal amount of ice cream may be good—they may like it because of its sweetness and they will almost certainly be benefited by the extra milk and cream which they thus get.

Without multiplying illustrations, it may be said that in general the proper place of sugar in the food supplies and eating habits of children is not in such concentrated forms as candy, nor in the indiscriminate and excessive sweetening of all kinds of foods, but rather as a preservative and flavor to facilitate the introduction into the child's dietary of larger amounts of the fruit and the milk, the importance of which to child health has been increasingly emphasized with each year's progress in our knowledge of nutrition.

The Inevitable Assurance

IT would be welcome to see a health book published without the inevitable assurance on the cover page that the author is "free from fads, theories," etc., etc. We do not think it is fair for publishers to handicap their authors by such reiterated protestations. Practically every health book that has come to our attention in the last six months has been thus labelled—that the writer plays no fads, that he has no fanatical views, and that what he has to say represents modern scientific judgment, and so on. As a matter of fact, few individual authors can avoid falling into fads because that is a characteristic of human nature.—*How To Live,* Sept., 1929.

Need for Better Occupation Returns on Death Certificates*

T. F. MURPHY, M. D.

Chief Statistician, Division of Vital Statistics, U. S. Bureau of the Census, Washington, D. C.

FOR a number of years the U. S. Bureau of the Census has been devoting a large part of its attention to the promotion of the satisfactory registration of births and deaths. The work has succeeded to the extent that satisfactory laws are on the statute books of all the states, with the exception of South Dakota, which failed at the session of the legislature in February to enact an adequate law.

In two states, New Mexico and Texas, satisfactory laws have been passed, but the registration in these states has not been given an official test to determine whether it is sufficiently complete to admit them to the registration area. This test is now being made in New Mexico. At the present time, approximately 95.5 per cent of the population of the United States is included in the death registration area, and 94.5 per cent in the birth registration area. While the promotion of registration has been given a great deal of attention by the Division of Vital Statistics, we have always kept in mind not only the desirability, but the almost absolute necessity of procuring more accurate returns. This phase of our work has been carried on for so many years that we consider it a part of our routine labors.

Each year industry grows increasingly more complex and the necessity for safeguarding the health of the workers becomes more urgent and of greater interest. A very large number of the great industrial plants of the present day have well organized health services whose aim it is to prevent accidents, to cure minor ills, to provide recreation, and to use means to build up and preserve the health of their employees. These services are usually supervised by physicians, professional nurses, and trained physical directors. Comprehensive campaigns are carried on urging annual physical examinations for workers; and the better understanding of the value of health gained is to the mutual benefit of the employee and the employer.

In many states employers of labor are required to take out acci-

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

dent and mortality insurance for their employees. This requirement is a powerful factor in improving the health and the conditions under which the employees work. The 1930 population schedule, as usual, will include inquiries relative to occupation. These furnish the foundation for determining the mortality in any particular line of work. The Bureau is now revising the index of occupations so that it will be possible to edit the occupational returns received on the population schedule, and the mortality returns on the same basis.

The demand for occupational mortality statistics has reached such proportions that the U. S. Bureau of the Census has felt that this part of the standard certificate should be enlarged, and that definite information of this character should be secured. Consequently, the Bureau and the Committee on Forms and Methods of Statistical Practice of the American Public Health Association prepared the revised standard certificate of death. This form was adopted by this Association through the Vital Statistics Section in October, 1928, in Chicago; and by the Conference of State and Provincial Health Authorities of North America on May 31, 1929, in Washington. Early in 1930, the federal government will take a decennial census of population, and as a result we shall have definite data relative to the 120,000,000 or more inhabitants of our country.

The committee on the revision of the International List of Causes of Death will meet in Paris this October. Taking all of the above facts into consideration it would appear that now is the ideal time to put into use the standard certificates so that the data will be comparable with the material gathered on the population schedules.

Everyone realizes that certain occupations are more hazardous than others. Employees in industries in which dust is a great factor, those exposed to exceedingly hot or cold temperatures, excessive moisture, poisonous vapors, and explosive compounds, are among the workers whose occupations are more hazardous than the average. Granted that a certain occupation is hazardous, the question arises, how hazardous is it? As a matter of fact, how much more dangerous is it than other occupations in the same industry or in other industries?

Occupation is without doubt one of the determining factors in a death rate. In reality, it is a double factor made up partly of the direct hazards of the occupation, and partly of the living conditions pertaining to the occupation which affect both the worker and his family. The presentation of adequate statistics of death, classified according to the occupation of the decedent, should therefore form a part of any comprehensive program for vital statistics. In order that the results may be of the greatest value, it is necessary that the

returns received on our transcripts conform as nearly as possible to the standard list of occupations used for the population census.

Some indication of relative occupational hazard is afforded by the mortality statistics compiled by occupations for the industrial policy holders of certain large life insurance companies; but no mortality statistics have ever been available in this country to give this information on a large scale. The U. S. Bureau of the Census has published no occupational mortality statistics since 1909, although some data were compiled for 1920. Considerable information is available in some of the states with reference to the number of deaths from accident or from disease which may be directly traceable to the workers' occupations. Such data are usually kept by the state department of labor or by the state workmen's compensation commission, but those deaths of workers in which the relation of employment to the cause of death is more or less uniform are seldom recorded. As an illustration, there has long been an idea that persons in certain lines of employment, such as locomotive engineers, were especially liable to die from affections of the kidney. The truth of this contention could be determined by death rates for such occupations.

For the computation of death rates for occupational groups, two kinds of material are needed—deaths classified according to the occupation of the decedent, and population data classified in the same way to form the basis for the rates. It is further necessary that the occupation classification of these two factors, so far as possible, be made on the same basis.

One of the principal difficulties in the way of compiling satisfactory mortality statistics by occupations is that of procuring an accurate return on the death certificate of the occupation followed by the deceased. A recent examination of more than 1,500 certificates selected from representative areas showed that only about 70 per cent contained occupation returns sufficiently complete to afford a basis for satisfactory classification. While information as to the industry is not absolutely required in all cases, it is essential to the accurate classification of a very large number of occupations, and there seems to be no way of assuring its presence when it is needed except to insist on accurate answers to all questions relating to occupation on the death certificates in accordance with instructions.

While the occupational data on the general census schedule are not all complete and satisfactory, the proportion of unsatisfactory returns is very much less than the 30 per cent shown for the death certificates. The reverse ought to be true. For the decennial census, the Bureau must appoint over 100,000 enumerators, who, in their

house-to-house canvass, are required to obtain from the housewife, or some other one, information concerning the 26 or more inquiries for each person on the population schedule.

The information on the certificate of death is usually obtained from a member of the family. As a general proposition, the undertaker, physician, or other person who gathers the information for the certificate of death, is more intelligent and should be more accurate than the average census enumerator. Furthermore, he is recording information with regard to occupations almost daily and not, as in the case of the enumerator, once in 10 years. The objection made in some quarters that this occupation query places a greater burden upon the undertaker or physician does not seem to me to be reasonable.

I have had experience in collecting many thousands of schedules relating to many different lines of industries and, as a result of this experience, I feel that one or two more intelligent questions would be all that would be necessary to obtain more correct data of occupations than the Bureau has been receiving. As an illustration, an examination of the returns made in one area shows that 88 transcripts were received for engineers, and on 54 of this number the occupation was given as stationary engineer—a very definite and satisfactory return. The remaining 34 simply had "engineer" and the Bureau could not, of course, classify them because we were unable to determine whether they were civil, steam, stationary, locomotive, metallurgical, sanitary, or any one of a number of other divisions in that line of work. How simple it would have been to have said "locomotive engineer," "civil engineer," etc.

A hurried examination of a large number of the returns shows that a word or two would be all that would be necessary to place approximately one-half of the unsatisfactory returns in the satisfactory class. As another illustration, we have hundreds of returns with "mill operator" as the occupation. Why not add or substitute "weaver," "spinner," "cotton mill," "stationary fireman," or other descriptive title. It is not at all necessary that a scientific or technical nomenclature should be adopted in order to furnish the Bureau with the information it desires. Simple terms are preferred. If the undertaker will answer the inquiries clearly in one or two words, it will be all that the Bureau requires.

In order that the occupational information may be returned in the same manner on the death certificates as on the population schedule, it is the intention of the Bureau, as soon as we can do so, to print small reference booklets similar to the *Physicians' Pocket Reference* and distribute them rather freely. This booklet in a broad way will

list terms to be avoided, and furnish a number of illustrations of the proper method of answering the inquiries. In this way we hope to place in the hands of all of those who make out death certificates sufficient information to enable them to secure correct answers.

The Bureau does not expect that it will be possible to procure complete occupational returns on all of the mortality certificates during the first, or even the second or third year. It does believe, however, that complete information as to the occupations of decedents is of such definite value that the use of the new certificates should be started generally at the beginning of the coming year. In fact, a number of the states have advised me that they are already using the new certificates or propose to use them next year.

It is needless for me to remind the state and city registration officials that, without their hearty coöperation in obtaining complete certificates, the U. S. Bureau of the Census is powerless to compile statistics of mortality, by occupations, of any value to the public, health officials, or sanitarians. By refusing to issue burial permits, the registrars can insist that all items on the certificates be completed, thus showing undertakers and others the value to the relatives, to the community, and to the state of having accurate and complete certificates. With the assistance of these officials the U. S. Bureau of the Census should be able to present valuable and interesting occupational mortality statistics.

Hygiene

SIR John St. Clair (born 1754) said:

"Knowledge may be compared to a small fraction of gold, dispersed throughout a great quantity of ore. In its rude condition, the strongest man cannot bear its weight or convey it to a distance; but when the pure metal is separated from the dross, even a child may carry it without difficulty."

So he proceeded to refine the existing publications on hygiene and issued his text-book in four volumes in the year 1807. Comparing this early effort with the latest of many successors one is struck by two things—first how little resemblance there is between the laws of health then and now, and secondly how much more concentrated is the essence than it used to be. One cannot claim that hygiene has become more readable. Those careful dissertations, flavoured with an esoteric insight and adorned with lively foot-notes of a narrative kind on, say, the relative merits of ale and beer as a beverage, or the advantages of dining at seven in the evening rather than at six o'clock; it is hard to see them replaced by snappy paragraphs on "The Digestive Tract."—From *The World's Health*, X, 2: 200 (Apr.–June), 1929.

The Health of Anabolic Nutrition*

FRANCIS LOWELL BURNETT, M. D.

Massachusetts General and Peter Bent Brigham Hospitals, Boston, Mass.

FOOD (is) the medicine of health and medicine the food of sickness."[1] "The form and structures of all living organisms are clearly dependent in a large measure upon the quantity and quality of their nutrient. A knowledge of these effects gives a deeper insight into the process of morphogenesis and a means whereby it may be experimentally controlled to a degree hitherto generally unrecognized."[2] The purpose of consuming food is to nourish the body, but on account of the delicate, intricate, and correlated processes of tissue construction and repair, essential or anabolic nutrition is only little by little becoming understood. The action of the vitamins in curing deficiency diseases, the beneficial effects of liver and protein food in blood regeneration, and the reduction of carbohydrate food in restoring the functions of the islands of Langerhans are perhaps phases of anabolic nutrition. On the other hand, when a patient's ways of eating and mode of living are still further taken into account for this kind of assimilation, a subtle cause of disease appears to be revealed, through the means to detect and maintain a state of health.

The essential nutrient substances for the development of this state of health seem to be assimilated only when the aliment passes through the digestive system within the limits of normal absorption. Accordingly, it is detected and maintained by the indexes of absorption. Food in the digestive tract is not in the body, but merely passing through; but when it is adjusted to comply with a final moulding of the intestinal contents, or the presumably normal form of the feces, and also with the time taken by a marked meal to pass through the digestive system, or intestinal rate, some diseased tissue becomes healthy.[3]

To consider nutrition from this point of view, the digestive system must be thought of as a highly perfected nutritive apparatus which was purposely designed for maintaining the integrity of the body. Such a mechanism cannot often be imperfect, and therefore variations

* Read before the Food, Drugs, and Nutrition Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

in its action are due to the food mixtures put into it. When the aliment is complete, properly proportioned, and thoroughly comminuted, it will complete its cycle of digestion and absorption, and apparently supply nutrient substances for the development and maintenance of an improved state of well-being. In this way, the cure of disease and the restoration of health may not be so much a matter of knowing more about disease, as it is of understanding, regulating, and later maintaining anabolic nutrition for the acquisition and control of health.

INTESTINAL INDIGESTION AND DEFICIENCY DISEASES

At present, health is a vague and variable condition, but the gulf that exists between health and a recognized deficiency disease has been conclusively demonstrated.[4] In this dietary experiment, rats given a vitamin poor food were small and weak, and had a lowered vital resistance; yet they were able to reproduce, and did not show obvious signs of disease. The cause of such a condition is evidently due to a failure of nutrient substances to build up the tissues. May not such a deficiency occur in patients from partially incomplete or other food factors? In the treatment of disease, an attempt is made to restore health. Without an understanding of an exact state of health some human diseases are not only very resistant to all kinds of treatment, but if once allayed are very apt to recur. Many of these are supposed to arise from a metabolic disorder, and as such a cause implies a failure of nutrient substances to build up the cells they are virtually deficiency diseases. Malabsorption is frequently an early and pronounced sign in many of them.[5]

With an understanding of the factors that produce an irritable colon, intestinal indigestion, and malabsorption, the care of the human body must be looked upon from a more intelligent point of view, and, instead of allowing malabsorption to progress until the remote effects of damaged tissue make a diagnosis possible, patients must be educated in the ways of right living to keep a check on the indexes of absorption. In this way they must prevent nutrient substances from going through instead of into them, and acquire and maintain the health of anabolic nutrition. Some persons have been educated in the practice of anabolic nutrition, and in this way metabolic or deficiency diseases may have been prevented. For the most part, however, these health measures have been applied to patients and the cure of disease, in order to obtain a more practical knowledge of the value of this treatment.

The vitamins have become established as necessary requirements for normal nutrition. On general principles, eating too fast and too

much, and the consumption of excessive fat, sweet, highly spiced food, and fruit, do not improve nutrition. The constant use of laxatives, oils, or enemas does not strengthen the body. With an understanding of the control exercised by the proximal colon in anabolic nutrition, the accessory as well as these faulty food factors is made subservient to bodily action, and the intestinal contents are entirely moulded into discrete masses that compose and regulate the presumably normal feces and intestinal rate. On the other hand, when these requirements are not generally fulfilled, the colon becomes irritable and intestinal indigestion ensues, as determined by soft and formless feces and a rapid intestinal rate.

THE PRACTICE OF ANABOLIC NUTRITION

In practice, anabolic nutrition is brought about by educating patients how to eat, rest, and exercise according to the action of their own nutritive apparatus. Inquiries into the ways of eating and mode of living of patients with metabolic or deficiency diseases invariably reveal one or more erroneous practices which must be corrected in order to reduce the irritability of the colon and prevent intestinal indigestion.

Patients are educated through the use of diagrams of the digestive system, roentgenograms of the normal and abnormal colon, pictures of the normal and abnormal feces, figures on the intestinal rate, and the record of a person controlling his health. From these illustrations and records they get a preliminary understanding of the subject, but more detailed instruction should be given from an examination of a week's record of their own nutrition. On the record should be entered the food consumed, the time spent at meals, the time and kind of dejection, and a test of the intestinal rate. For this test the patients ingest 25 c.c. of millet seed or 100 gr. of charcoal immediately after an evening meal. Then the hours that elapse from the ingestion to the first and last appearance of the marker in the feces are noted. With patients having one, and sometimes two normal dejections daily, the marker first appears in about 63 and is last seen in about 134 hours.

From these records of nutrition brought in at varying intervals according to the health measures necessary to adjust, anabolic nutrition may be attained and the disease relieved. The care of the person should not end here, however, because anabolic nutrition must be subsequently maintained to prevent a recurrence, and to cure the disease. Some patients readily acquire a knowledge of the food factors and ways of living that influence nutrition and carry out the

principles afterward. Others find exact ways of eating difficult to understand and maintain. Ordinarily, patients should observe the feces daily and know enough to keep them normal by adjustments of diet, etc. As an additional check on anabolic nutrition, they should test the intestinal rate and weigh the body every month, and finally have a health examination once a year. The records of a few patients taught to cure metabolic or deficiency diseases by these principles of treatment follow. A more detailed study of some of them has already been published,[6] while others will appear in due time.

An English Jew, 31 years old, has had psoriasis for 13 years. Recently it has become worse and changed to dermatitis exfoliativa. He has also lost 20 lbs. within the last year (see Figure I). He eats a great deal of food, very rapidly; has 2 or 3 soft dejections daily and sometimes gets diarrhea. He was advised to eat slowly and less food. (19. VI. '22)—Has a fair record but the colon has been irritable, the dejections soft and formless; and the intestinal rate is 13–63 hours. (11. VII. '22)—The patient has followed instructions faithfully, acquired normal dejections in a month after the last visit, and the skin has gradually become normal. The intestinal rate is 74–141 hours, and his weight has increased 15 lbs. (see Figure II). (11. III. '24)—Skin continues healthy. Feces generally normal. No record or rate. (3. I. '28)—Continues to be careful of food, and dejections are generally normal. Skin healthy.

FIGURE I—Illustration of marked malnutrition of a man with a metabolic skin disease.

FIGURE II—The healthy skin of the same man after carrying out the principles of anabolic nutrition for 4 months.

A single man, 39, has had recurrent iritis and indigestion every autumn for 6 years. He had gained 50 lbs. in the last 10 years. He ate rapidly and a great deal of starchy food. Weight, 192 lbs. Had 2 large dejections daily. Was advised to reduce food, especially starchy food. (19. XI. '26)—Dyspepsia somewhat less. Feces continues soft and formless with a rate of 19–43 hours. Still eats too much starchy food. As a moving picture operator, his hours are irregular. Was advised to eat a moderate breakfast at 10 A.M. and a dinner at 4.30 P.M. (21. I. '27)—Had an attack of diarrhea a few weeks ago and had slight inflammation of eye. Rate now 18–89 hours, and weight, 172 lbs. (2. VI. '27)—Eyes continue healthy. Dejections becoming formed; rate 41–90 hours, weight, 162 lbs. (18. XI. '27)—Symptomatic indigestion has entirely disappeared and he feels better than he has for years. Is happy on two meals. Feces formed with rate of 43–90 hours, weight, 166 lbs. (19. IV. '28)—Feels well and eyes have been healthy during the winter. Feces generally formed with a rate of 42–90 hours, weight, 170 lbs. Was advised to eat less. (15. XI. '28)—He gets indigestion at times from too much fruit. Rate 42–96 hours, weight, 162 lbs. (16. V. '29)—Feels well, but gets soft dejections from too much food. Rate 43–97 hours, weight, 168 lbs. Less food advised. (29. VI. '29)—Had another attack of iritis, but it was very mild, and responded to a reduction in food. Feces often normal with rate of 24–120 hours, weight reduced to 155 lbs. (27. VII. '29)—Eye healthy again and he feels unusually well. Dejections entirely normal, with a rate of 72–144 hours, weight, 153 lbs.

A widow 64 years old has had arthritis for 7 years. For the last 3 years it has been so severe she has been unable to work. She has a poor appetite, takes physic regularly, and has lost 15 lbs. in 2 years. Weight, 108 lbs. She was told to eliminate physic, eat fruit for two meals, try regularly to have a dejection an hour after breakfast and again before going to bed, but that her dejections would be irregular for a few weeks. (31. VIII. '27)—Still has pain. Dejections are formed and becoming regular without physic, rate 12–134 hours. (28. IX. '27)—Is beginning to feel stronger and has less pain. Dejections have become regular with a rate of 20–156 hours. (19. X. '27)—Has been worrying a good deal and has not slept well. Rate 15–134 hours, weight, 103 lbs. (11. I. '28)—Has much less pain and is able to do a great deal more. Feces generally normal with a rate of 36–108 hours, weight, 106 lbs. (28. III. '28)—Is much improved, rate 36–134 hours, weight, 109 lbs. (24. X. '28)—No longer has pain and joints are freely movable, rate 38–156 hours, weight, 112 lbs. (12. IV. '29)—Has had a little indigestion and pains have returned, rate 15–91 hours, weight, 118 lbs. (10. VI. '29)—She had been eating too much fruit the last month, but recently has had good absorption, with a rate of 38–120 hours, and the indigestion and pains in her joints have entirely disappeared. Weight, 118 lbs.

THE ANABOLIC PROCESSES

Verworn states:

The fundamental fact of life is the metabolism of living substance, which is continually and spontaneously undergoing decomposition and building itself up anew with the help of food substances it takes in. Among the organic matters which compose living substance, proteids form the most important part. . . . The proteids and their compounds . . . are . . . stable . . . , whereas the hypothetical combination which lies at the center of organic metabolism is extraordinarily

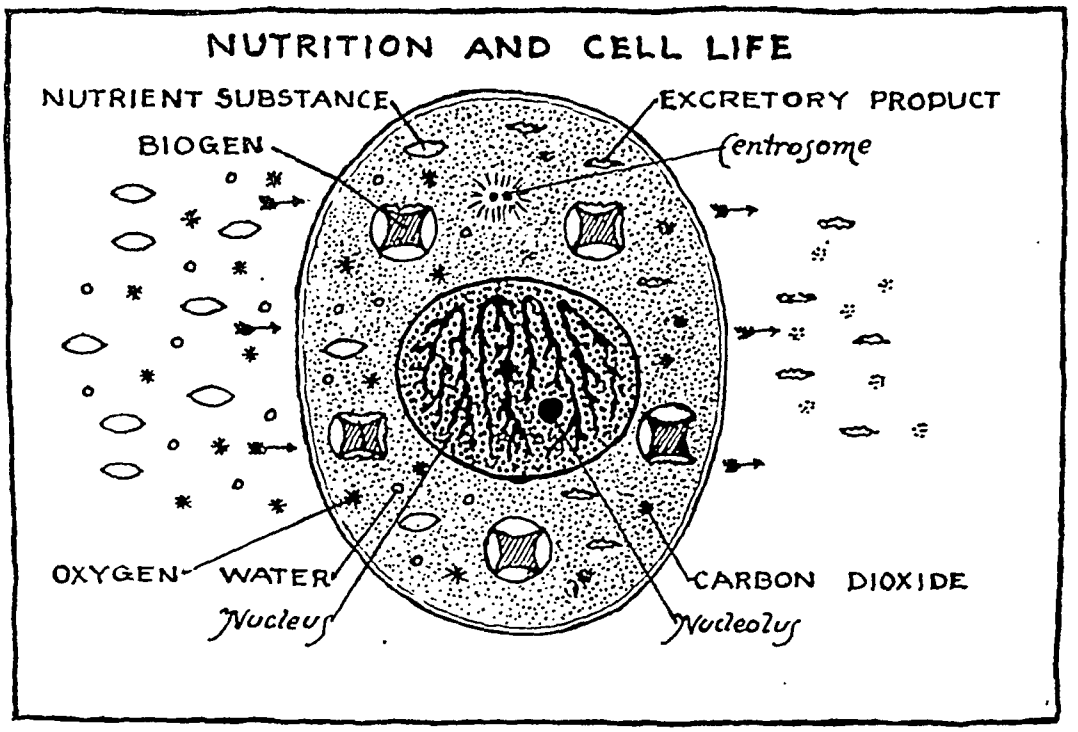

FIGURE III—A diagrammatic illustration of the nutrition of a cell. Nutrient substances, water, and oxygen are seen entering on one side, and excretory products and carbon dioxide are passing out at the other.

labile and continually undergoing spontaneous decomposition. . . . We have to think, therefore, not of ordinary proteids . . . but of still more complicated combinations, the atoms of the molecule of which have a strong tendency to group themselves in new arrangements. Owing to their fundamental importance, these combinations have been termed " biogens." When we come to inquire how such labile biogen molecules are built up out of proteids of food, our knowledge is much restricted. Doubtless the intramolecular addition of inspired oxygen has much to do with it, for living substance deprived of oxygen loses its . . . tendency to decomposition. . . . The decomposition of living substance is always associated with the formation of carbon dioxide. If we accept these views, . . . assimilation is the reformation of biogen molecules by those already existing, aided by food stuffs.[7]

This process is graphically illustrated in Figure III.

Active cells are known to use nutrient substances from the blood; for specimens taken simultaneously from the jugular and mammary veins of a milch cow and analyzed show less sugar and tryptophane in the abdominal vessel,[8,9] thus indicating that these substances were assimilated by the active mammary cells for the formation of milk. The utilization of nutrient substances for the growth of cells in tissue cultures has also been demonstrated.[10]

Young bits of heart, liver, skin, and intestine from chicken embryos grow well in a pure saline fluid, but 11-day tissues require "growth promoting hormones" of a more complex composition.

Serum supplies such a medium, and all tissues grow well through a number of generations. In yeast extract, however, heart muscle alone fails to grow even after the addition of serum, and therefore yeast evidently has an inhibiting effect on the growth of this tissue. After some time liver in serum ceases to form parenchymous, but instead develops less complex fibroblast-like cells. Such a deviation of cellular growth has also been observed in scorbutic guinea pigs.[11] With a complete food, sections of the teeth show an orderly array of the odontoblast layer closely applied to the dentin. In early scurvy, this layer becomes separated, the cells shrunken, and irregular calcium deposits form; but the principal substance is a gelatinous material which is supposed to be a defective product of the odontoblasts. Accordingly, when these highly specialized cells do not receive normal nutrient substances, they exhibit a perversion of function and a dystrophic growth.

A contrast in the gross appearance of deficient and normal bone may be seen in the jaw of a guinea pig shown in Figure IV. This is one of a group which in early life was fed a scorbutic diet, and developed the poor, decalcified material shown in the anterior portion. Before the deficiency disease became too extreme, the animals were given a complete food, and the strong normal bone, seen growing over the other, formed.

From the improved nutrition brought about in patients with psoriasis, iritis, and arthritis, it is evident that nutrient substances

FIGURE IV—The jaw bone of a guinea pig showing the development of a poor, decalcified bone, in the anterior portion, from a scorbutic diet, and strong, normal bone, in the posterior part, from a complete food. (The illustration is used through the kindness of Dr. Percy R. Howe of Boston.)

must have been assimilated by the cells of the skin, eyes, or joints to relieve them of a deficient condition and restore them to health.

The adjustment of a patient's ways of eating and mode of living to acquire this state of health has been brought about by recognizing the digestive system as a highly perfected nutritive apparatus, in which there is a mechanism that controls anabolic nutrition. This is a mechanism by which a secondary digestive pouch is formed of the proximal colon by pulsating constriction rings. In this pouch, nutritive material is kneaded back and forth until a certain kind of absorption occurs, and then the rings mould the intestinal contents into discrete masses that compose the normal feces. This action of the proximal colon has long been known to be normal in many vertebrates.[12] The action is so complex, and so delicately adjusted, that the requirements necessary to bring it about have not been generally observed in man, because the food must be complete, thoroughly comminuted, and properly proportioned.

Rest and exercise also appear to influence this function. Thus the proximal colon serves as an exact, automatic, and sensitive control of the absorption, which is evidently nicely correlated with digestion and assimilation, and regulates the nutrient substances the tissues receive from the food in anabolic nutrition. By the acquisition and subsequent control of this kind of nutrition, a heretofore unrecognized state of health is evidently acquired and maintained, which seems essential for the prevention or cure of some metabolic or deficiency diseases.

Essential Features in the Design of Sanitary Drinking Fountains*

THE Committee on Plumbing of the American Public Health Association has had insufficient time to prepare a detailed final report upon the subject of the Design of Sanitary Drinking Fountains, as a thorough study of this subject would require circularization of the manufacturers, schools, and public health authorities, to secure comprehensive information as to the nation-wide aspect of the subject. It is desired at this time, however, to present a progress report.

There appears to be a lack of appreciation of the sanitary significance of certain features of the design of drinking fountains, because frequently improperly designed units are installed in schools, railroad stations, and other public places, where in most cases the equipment has been carefully studied before selection. The possibility of infectious diseases of the respiratory tract being transmitted by the use of insanitary drinking fountains has been demonstrated. A vertical jet fountain with an exposed nozzle may be likened to a common drinking cup, which has been condemned by practically all public health agencies. At present, therefore, it appears that both sanitary and insanitary fountains are available to the public; that a public health problem exists; and that apparently on the part of public health authorities there is a lack of appreciation of the necessity for controlling and supervising such fountains. It is very appropriate that the American Public Health Association use its influence in bringing the essential features in the design, construction and operation of sanitary drinking fountains to the attention of its members, the manufacturers of such equipment, and the public.

A committee of the American Water Works Association, similar to this, reported on this subject in 1924 and concluded as follows:

1. All types of drinking fountains with vertical jets are to be condemned.
2. Most types of drinking fountains with slanting jets are to be condemned.
3. To be sanitary, drinking fountains should conform to the following specifications:
   a. The jets shall be slanting.
   b. The orifices of the jets shall be protected in such a manner that they cannot be touched by fingers or lips, or be contaminated by droppings from the mouth, or by splashings from basins beneath the orifices.

* Report of the Committee on Plumbing, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

c. The guards of the orifices shall be so made that infectious material from the mouth cannot be deposited upon them.

d. All fountains shall be so designed that their proper use is self-evident.

Section 61 of the Railroad Sanitary Code of the U. S. Public Health Service reads as follows:

If drinking fountains of the bubbling type are provided in any railway station, they shall be so made that the drinking is from a free jet projected at an angle to the vertical and not from a jet that is projected vertically or that flows through a filled cup or bowl.

It will be noted that this portion of the railroad sanitary code conforms with the above mentioned conclusions.

Careful consideration by the committee of the requirements in the design, construction and operation of drinking fountains whereby such structures may be in reality sanitary, indicates that the following details should be considered.

1. The fountain should be constructed of impervious material, such as vitreous china, porcelain, enameled cast iron, other metals, or stoneware.

2. The jet of the fountains should issue from a nozzle of non-oxidizing, impervious material set at an angle from the vertical, and at an elevation above the edge of the bowl, so that the end of the nozzle will not be flooded in case a drain from the bowl of the fountain becomes clogged.

3. The end of the nozzle should be protected by non-oxidizing guards to prevent the mouth or nose of persons using the fountain from coming into contact with the nozzle.

4. The inclined jet of water issuing from the nozzle should not touch the guard, thereby causing splattering.

5. The bowl of the fountain should be so designed and proportioned as to be free from corners which would be difficult to clean or which would collect dirt.

6. The bowl should be so proportioned as to prevent unnecessary splashing at a point where the jet falls into the bowl. Self-cleansing anti-splash rims are recommended.

7. The drain from the fountain should be connected to a separate waste pipe.

8. The water supply pipe should be provided with an adjustable valve fitted with a loose key or an automatic valve permitting the regulation of the rate of flow of water to the fountain so that the valve manipulated by the users of the fountain will merely turn the water on or off.

9. The control valve should be operated preferably by knee or foot action to avoid possible hand contamination.

10. The height of the fountain at the drinking level should be such as to be most convenient to persons utilizing the fountain. The provision of several step-like elevations to the floor at fountains will permit children of various ages utilizing the fountain. Elevations may be difficult to provide, however, at fountains recessed in walls.

11. The rate of flow and the pressure should be such that the water will not splash over the bowl. It should be at a rate not less than ½ gallon per minute and at nozzle pressure not exceeding 5 pounds per square inch.

12. The waste opening and pipe should be of sufficient size to carry off the water promptly. The opening should be provided with a strainer.

Obviously, the control and supervision of public drinking fountains should be delegated to local health authorities. It is the committee's impression, however, that few local ordinances on this subject have been promulgated. In certain instances, however, boards of education have specified in their building standards what types of drinking fountains must be installed in approved school buildings. It is felt, therefore, that this committee might well prepare specifications for sanitary drinking fountains for the guidance of members of this Association.

The conclusions of the committee of the American Water Works Association given above indicate that the essential features of sanitary drinking fountains are sloping jets which are so located as to be above the level of the water draining from the bowls. Many of the so-called sanitary drinking fountains available at present do not fulfil these requirements. In fact, the vertical jet type fountain seems to be the most popular. It is necessary, therefore, that publicity be given to the essential features of design of these fixtures.

The use of sanitary drinking fountains involves several secondary problems, such as location, water supply, and cooling. It would seem a relatively simple matter to locate drinking fountains properly, and yet such fountains have been observed in toilet rooms, vestibules, baggage rooms, and isolated in improperly lighted hallways. It is not felt that the mere location of a drinking fountain is of great sanitary significance; yet it is apparent that the education of the public in matters of cleanliness and hygiene will be hindered by the inference drawn from observing such structures in toilet rooms or similar locations. Esthetic considerations must be considered likewise.

It goes without saying that the water obtainable through drinking fountains should be of satisfactory sanitary quality. The pressure of the supply is also of considerable importance, because if the pressure is insufficient the rate of flow of the water is too slow to produce the desired size jet, making it difficult to secure water. This deficiency may be caused by undue resistance to the flow of water by the jet and control valve of the structure, or to low pressure on the distribution system. If the pressure is too high, the jet is too strong and water is splashed over those using the fountain. If, on the other hand, the pressure is insufficient, the jet may not reach the proper height and there will be a tendency for those desiring water, especially children, to secure it by placing their hands or small utensils in the bowl of the fountain. Frequently valves are provided on fountains for adjusting

the rates of flow, to provide the desired size jet. Automatic pressure control valves are preferable, if not necessary, with slanting jet fountains, as the pressure of the water supply varies throughout the day.

Drinking fountains are also subject to the limitation imposed by the necessity of cooling a relatively large volume of water, because warm water is not attractive to the public. The quantity of water flowing through a drinking fountain is much in excess of that which would be used were individual drinking cups available, so obviously the amount of ice necessary to cool the water issuing from drinking fountains is greater than otherwise would be the case. It is felt that this feature is one of the salient reasons why drinking fountains are not so popular with the public as they were expected to be by those interested in providing sanitary means of securing potable water. Mechanical refrigerating equipment is available, however, for cooling the water. The cost of such installations is about twice that of equipment for cooling with ice. Many of these units, therefore, are being installed. Sulphur dioxide and other gases are being used as the refrigerating agents.

It should be emphasized that the design of this equipment should be such that the gas will not enter the water supply of fountains in case of leaks; otherwise sulphurous acid or other compounds would be formed in the water. Obviously, the fountains and refrigerating equipment should be designed and installed in such a manner that cross connections are not formed between the water supply and drainage systems.

DISCUSSION

H. A. WHITTAKER

Director, Division of Sanitation, Minnesota Department of Health, Minneapolis, Minn.

ONE of the early studies demonstrating the transmission of communicable diseases by means of insanitary drinking fountains was undertaken by Pettibone, Bogart, and Clark, at the University of Wisconsin, in 1914.[1] They studied an epidemic of septic sore throat at this university which was quite definitely associated with certain drinking fountains then in use. As a result of their studies, they recommended the slanting stream type of fountain. During the year 1917,

investigations were conducted by the writer at the University of Minnesota, which showed that 80 per cent of the fountains examined at the university were infected with streptococci.[2] As a result of this investigation, a type of fountain was designed with the view of eliminating, as far as practicable, the dangers associated with the types then in use. Bacteriological results obtained after the installation of the new design showed that the desired results had been accomplished.

For a time it appeared that health officials were taking a keen interest in the drinking fountain problem, but for several years only a lukewarm interest has been taken in the situation. During the past two years, I have paid special attention to the drinking fountains located in public places in cities that I have had occasion to visit, throughout the country. I have been astounded at the number of apparently insanitary types of drinking fountains in nearly every section visited, including Minnesota.

I was very deeply impressed during the past year, while visiting a large public school, to see a long line of kindergarten children led to a drinking fountain of a most insanitary type. In this case, the fountain was of the vertical stream type, so designed and operated that it was practically necessary for each child to place his lips around the point at which the water emerged. To make the situation still worse the fountain was operated intermittently and after each operation the water receded into the nozzle carrying with it any droppings from the mouth of the consumer. This infected material remained there to be deposited in the mouth of the next consumer using the fountain. I counted a line of 25 kindergarten children at this fountain, each—so to speak—sucking the same metal bulb. I can scarcely imagine any more direct way of transmitting communicable diseases associated with discharges from the mouth.

The situation in this state became so apparent that on January 15, 1929, the Minnesota State Board of Health passed the following resolution which was sent to the public throughout the state:

WHEREAS, public drinking fountains have largely replaced the common drinking cup and are provided in a great many places accessible to the public, and

WHEREAS, investigations have shown that disease producing bacteria may be transmitted from one person to another through the use of improperly constructed or improperly operated drinking fountains, and

WHEREAS, the observations made by the State Board of Health have revealed the presence of insanitary types of drinking fountains in many public and semi-public places throughout the state, therefore, be it

RESOLVED, that the attention of the public be drawn to the fact that not all drinking fountains are satisfactory, and that to be sanitary, drinking fountains should conform with the following general requirements:

1. The jet of water emerging from the fountain should be slanting so that discharged water does not fall back onto the surface.

2. The orifice from which the water emerges should be protected in such a manner that it cannot be touched by the lips or be contaminated by droppings from the mouth or by splashings from the base beneath the orifice.

3. An adequate supply of pure water under sufficient pressure properly controlled should be provided in order to insure satisfactory operation of the fountain.

The board considers the situation to be serious and, after giving the public adequate time to consider the problem further, more positive action may be taken to remedy the condition.

When one stops to consider the number of different communicable diseases that are transmitted through discharges from the mouth and nose, it is easy to conceive that insanitary types of drinking fountains may become an appreciable factor in the transmission of the respiratory diseases.

The committee has made an excellent report, and I hope it will be instructed to continue its good work and to prepare a set of standard specifications for the construction and operation of sanitary drinking fountains.

Milk-Borne Outbreaks of Disease in the United States and Canada in 1928

A TOTAL of 43 milk-borne epidemics involving 2,129 cases and 94 deaths were reported by state and provincial health officers in the year 1928. Twenty-four of these outbreaks were of typhoid fever, involving 408 cases with 41 deaths. Ten of the outbreaks were of scarlet fever, involving 407 cases with 5 deaths. There were 3 outbreaks of undulant fever, involving 29 cases with no deaths. The most serious outbreak was that of septic sore throat at Lee, Mass., involving 950 cases with 48 deaths.

The danger of typhoid carrier infection in relation to milk is shown in an outbreak of typhoid fever in San Francisco, involving 63 cases and 11 deaths, in which a carrier was employed at the capping and bottling machine at a pasteurization plant. The pasteurization of the milk supply was satisfactory, but the carrier evidently infected the milk when bottles were returned for refilling and capping. A typhoid outbreak in Sullivan County, N. Y., involved 7 cases and 2 deaths. A carrier responsible for the outbreak was found on investigation to have caused about 35 cases of typhoid fever over a period of 20 years. This particular carrier operated a store and a one-cow dairy and distributed raw milk. The outbreak at Rutland, Vt., involved 16 cases and 3 deaths. The typhoid carrier was found among the employees of the dairy on whose route the cases occurred. The carrier was a man 63 years of age, who had typhoid fever at the age of 15.—*Monthly Bull.*, Indiana State Board of Health, August, 1929, p. 122.

Research in Student Health

R. W. BRADSHAW, M. D.

College Physician, Oberlin College, Oberlin, O.

THE field of student health offers opportunities for research found probably nowhere else in the realm of the medical sciences. This branch of medicine is comparatively new. The viewpoint offered is unique and is not to be found in the other branches of preventive or curative medicine. It has become a specialty in which are incorporated certain features from the field of clinical medicine, others from preventive medicine and public health, and still others which have been born in college and university departments of physical education.

Because it is new and because it has this background it opens up new avenues of approach to the solution of many health problems whose significance has not been appreciated in the past. In this new enterprise we find opportunities for the study and correlation of facts and sciences which have hitherto been valuable in their own sphere, but have lost much of their practical social value because there were no means of arriving at their full interpretation. Research in physical education, clinical medicine, and public health, is currently achieving fresh objectives. New avenues of social service are being rapidly opened. In the realm of science generally and especially in the field of the biological sciences, relationships are of greater significance than isolated factors. Progress is bound to be both stimulated, and more effectively directed, by the natural impact of one branch upon another. The essential unity of all problems relating to human health and discoveries growing out of their study finds full opportunity for expression in the work of the department of student health. Constructive ideas conceived and nurtured in one branch can be adopted and applied to the full measure of their potential usefulness in allied fields. Developments and discoveries in any direction can be adjusted to throw a broad as well as an intensive light. In the student health laboratory one may study the effects upon carefully selected and easily controllable material of propositions germinated in each of the sciences concerned with health. Here lies a field fertile in its possibilities for planning, administering, and testing in a practical way the most significant correlations. That it has long been neglected makes it all the richer in its potentialities.

In the field of student health we may promptly dismiss from our consciousness the inspiration to investigate merely to satisfy the desire for exploration. The million students who every year present themselves to us furnish invaluable material and tools for the working out of problems which *directly* affect their present and future health, and their usefulness to the world. The immediate and practical social value of research in student health is incalculable. Is it not significant to discover, for example, whether the students who have experienced a well rounded 4-year health program are more able to live well after leaving college than those not enjoying this phase of education? Have they cultivated a more scientific attitude toward disease? Storey[1] has contributed an outstanding monograph in this field in which he points out the opportunity the student health service has to produce graduates who will be characterized by "habits of periodic health examination" and by an "experienced discriminating judgment in the selection of scientific health advisers, services, and consultants." Diehl[2] has given an excellent summary of the research already done in this particular field and has proposed a most comprehensive program for future efforts. Our institutions of higher education have it in their power to send out 100,000 graduates annually, taking places of leadership in their various communities and in the nation, who could in one generation bring about the practical application of our knowledge of disease prevention and health conservation.

Certain researches may and should serve to stimulate a restudy of our convictions about the value of medical or surgical treatments which have hitherto held unassailable positions in medical practice. For example, Forsythe[3] concluded from his investigation of the incidence of acute disease in tonsillectomized and non-tonsillectomized students that: "There seems to be little if any significant difference between the health of students who came to the University of Michigan with or without having had the operation of tonsillectomy."

One difficult problem which should be worked out carefully is that of health appraisal. A system of evaluating physical defects, health habits, illness disability, and the individual's health status on an established uniform basis and of conferring health grades similar to our methods of awarding scholarship grades would be of great value in this work and would offer an excellent runway from which to take off for improvement in many phases of the work as well as be a stimulus to the student to better his condition. Standards of this kind would stimulate studies which involve comparisons between health conditions of a general population group and those on the campus. Such standards are indispensable in properly evaluating the results of procedures

currently used in health conservation. Smiley[4] at Cornell University has attacked the subject and has worked out a useful basis, a modification of which has already been utilized in industrial medicine by Sappington.[5]

PREVENTION OF ACUTE DISEASE

There are a million students daily bringing to our door ailments which previously have never come to the attention of anyone who was capable of, or interested in, recording and studying them systematically. The average patient consults the physician only when symptoms have advanced to such a state that relief is demanded. The student health service invites the patient to seek scientific medical advice at the earliest suggestion of variation from the normal. This is the stage of disease, in the large, never before presented to the physician for study. These are the physical conditions which offer a mass of data crying for interpretation. In this stage of disease prevention can be practiced in a telling way. Here we have untold opportunity to offer humanity proven theories regarding health conservation which will be of large social value.

PREVENTION OF DEGENERATIVE DISEASES

Another challenge which faces those responsible for the health of youth lies in the increase of the insidiously developing chronic diseases such as cancer, arteriosclerosis, heart disease and diabetes. Although the life span of the infant has increased 10 years since 1900, the expectancy of the middle aged person shows no significant improvement. A *larger* percentage of the population each year is reaching the age period when the chronic degenerative diseases demand their toll. Every year chronic diseases of the heart, kidney, and arteries select a distressingly large proportion of their victims from those in the prime of life, and we are practically helpless in preventing these disasters. But there are many reasons to make us believe that the infections of youth, and the health habits established during college life, may very well be contributing factors in such deaths, and prevention of these pathologic tendencies may be possible in the college age period. Can we not determine what significance should be attached to the many transient albuminurias we find? What of the many transient hypertensions or glycosurias or the psychoneuroses? Some of these questions require years for solution, but if a beginning be made in the college age period with careful and complete records of even the minor ailments, in most of our institutions it will be possible through the alumni organizations to obtain fairly complete histories of major health data regarding a large percentage of graduates.

Correlation of these data with health records of the students for four years in college will enable us certainly to solve some of the problems mentioned above.

MENTAL HYGIENE

Only comparatively recently have functional mental disorders been studied scientifically and we are beginning to realize how close is the relationship between emotional imbalance and failure in life. Jastrow[6] says, "This is the psychoneurotic age. As the result of our strenuous order of living the nervous and mental disorders outnumber all other forms of ailments. One dismal prophecy announces that, if the increase of psychoneuroses and mental disorders continues for another generation, there will be about enough mentally fit individuals in the community to take care of the mentally unfit and the human race will have no other occupation."

A distressingly large percentage of our graduates are victims of emotional imbalance which condemns them to a life too full of misery. When faced with the challenge of adjusting themselves to the baffling array of demands set by our modern mode of life they develop a pathologic behavior which precludes the possibility of a wholly successful outcome in their pitiful struggle. They become helpless dependents, incapacitated with periodic aches and paralyzed with fears. Is it not our responsibility to learn how to cultivate in our students an emotional control which will enable them to meet the trying situations which life presents? The youthful student steps from his sheltered home into college life with its scholastic and social demands immediately imposed upon him in a wholly unfamiliar environment. The customary supports have been left behind. Right here we are presented with a unique opportunity to study the outcropping and development of previously unsuspected emotional stigmata. He appears at the health service with a complaint of incapacitating fatigue; or in an attempted escape from reality he may develop a digestive disorder which drives him to bed in the infirmary. We shall not trace him through his sombre future, but stop to consider the challenge he offers us for the solution of his dilemma, which is the dilemma of thousands. It is a lamentable fact that up to the present time absolutely no effective program for rehabilitating those afflicted with functional mental disorders has been presented. Occasionally we achieve what seems to be a remarkable cure, but these are the exceptions rather than the rule. Can we not make more accurate measurements of the emotional life of the individual? Can we not measure objectively, with the help of the psychiatrist, the psychologist, the personnel

officer, the student's emotional life, his ability to adapt himself to his environment, his variation from what might be established as normal? Can we not then train his emotions?

HEALTH AND ENVIRONMENTAL FACTORS

University and college life imposes on the individual a unique set of conditions. These conditions pertinently affect the health of the student. There is no other large group of people who can be so well moulded into an experiment as the average college student body. They are intelligent and coöperative. Our observations may be carefully made and accurately checked. With the inauguration of the personnel work in our colleges we have placed at our disposal an array of pertinent facts concerning each individual never before assembled. The comparison of the health status of a group exhibiting a certain set of characteristics or subjected to certain environmental factors either before or during the college years with the health status of another selected group will reveal conclusions of widespread applicability in our efforts at health conservation. It should be remembered that the mere realization of the relationship between incidence of tuberculosis and financial status of the patient was one of the most important factors causing the rapidly declining death rate of that disease witnessed during the past few years.

At Oberlin College the writer[7] investigated the incidence of illness among self-supporting and financially independent students, and found a significant difference in the amount. The students working their way suffered an incidence approximately 30 per cent greater than their financially carefree colleagues. Many other correlations of this sort may easily be worked out and will usually lead to worthwhile conclusions.

NUTRITION

The student health service is in a strategic position to undertake systematic and practical experiments in the field of nutrition. Emerson[8] has demonstrated a relationship between scholarship and the state of nutrition. There is general agreement that a close relationship exists between nutrition and general bodily resistance to disease. It should be comparatively easy to institute experiments which could be well controlled and carefully checked in a few of our institutions, the results of which should perhaps emphasize distinct advantages of a particular diet in its ability to stimulate and sustain hard mental work. Ever since the classic studies of Chittenden and his coworkers, we have been inclined to believe that a comparatively low protein allowance may be tolerated without the development of any signs of

malnutrition, or indications of any decrease in well-being. Many workers are beginning to doubt the validity of this teaching.[9] We are not at all convinced that the commonly recommended diet of our college boarding halls contains proteins, adequate either in quantity or quality.

EPIDEMIOLOGY

The periodic dismissal of a large number of students at vacation time, and their reassemblage from all parts of the country into a set environment several times a year, places under our immediate control factors which are significant in determining the nature of epidemics. In this situation elements such as virulence of virus, duration and completeness of immunity, intimacy and extent of contact, which are determining factors in disease spread, are forced to the surface where they may be isolated and studied as distinct units.

To mention but one of our problems in epidemiology, the common cold, the most prevalent disease with which we deal, and the greatest time-waster for students, has not yet been brought under control. Although we have not determined the cause, we are convinced that its contagiousness is its strongest offensive weapon. Careful researches into this phase of epidemiology will yield rich rewards.

SUMMARY

Student health is a new science. In this field is offered an opportunity to study disease and health from a new vantage point, and an opportunity to correlate effectively health data derived from various sources. In the health service are assembled data regarding the stage of disease never before systematically studied on a large scale. Unique opportunities for research are offered in the field of health appraisal, disease prevention, nutrition, mental hygiene, and epidemiology the results of which will be of immediate practical social value.

EDITORIAL COMMITTEE

MAZÝCK P. RAVENEL, M.D., *Chairman* HOMER N. CALVER, *Managing Editor*

C. C. YOUNG, LOUIS I. DUBLIN, PH.D., E. R. HAYHURST, M.D., MERRILL E. CHAMPION, M.D., ARTHUR P. MILLER, C.E., HENRY F. VAUGHAN, D.P.H., EVART G. ROUTZAHN, C.-E. A. WINSLOW, DR.P.H., WALTER S. FRISBIE.

THE FIFTY-EIGHTH ANNUAL MEETING

THE meeting in Minneapolis was a success, though the attendance was not up to what was hoped for and expected. There were 196 papers presented, many of which were of high quality. While no startling discoveries were announced, the several papers on the streptococcus and its relation to septic sore throat, scarlet fever, and erysipelas, which were read before the Laboratory Section, had especial value, looking toward the clearing up of the many difficulties which confront the bacteriologist in his study of this great enemy of the animal kingdom. Though oral hygiene has attracted much attention during the past few years, only one paper on the subject appeared on the program, though the Child Hygiene Section had nine sessions, alone or in connection with kindred organizations.

All the other sections of the Association were well represented, and many contributions of practical as well as scientific value were presented. The Public Health Education Section had an especially full program.

Among the foreign representatives attending the meeting were: Dr. Wu Lien Teh, Chief Consultant of the Minister of Health of China, and Director of Manchuria Plague Prevention Service, who delivered a paper before the Epidemiology Section entitled "Epidemic of Plague in Manchuria"; Dr. Jacobo Fajardo, Director of the Philippine Health Service, who gave a brief talk at the Health Officers Section dinner regarding advances in health conditions in the Philippines since the pioneer work of Dr. Heiser; and S. W. Tay, Chief Engineer of the Hawaii Health Department, who was the official representative for the Hawaiian Government.

Perhaps the chief interest in the session for members of the Asso-

ciation lay in the adoption of the amendments to the Constitution, the substance of which has already been published in the JOURNAL. These make for continuity of effort, and increase the democratic character of representation and selection of officers. For the first time a President and a President-elect were chosen. The latter will take office at the close of the annual meeting in 1930, after a year of close connection with the affairs of the Association.

The retiring President, George W. Fuller, gave much time to the reorganization plan, and was directly responsible for many economies as well as increased efficiency of organization, the gratifying result being that the Association is in a better financial condition than at any time in its history, and there is every prospect that it will continue in this favorable position.

All publications of the Association, including the JOURNAL, were put under a special committee to be selected by the Executive Board. Heretofore, the JOURNAL, and all other publications, have been directly under the Executive Board.

The citizens of Minneapolis as well as the State of Minnesota showed every hospitality possible. The arrangements were excellent, the Chairman of the local Committee being also the Mayor, who presented to President Fuller a key to the city, which, as he said, would open the doors of any places into which we wished to go, and also the doors of any other places into which we had strayed and might wish to get out of. The thanks of the Association are due to all who took part in making the meeting a success, and especially to Dr. R. O. Beard, who took on his shoulders much of the active work connected with preparing for the meeting.

DIPHTHERIA CARRIERS

THE health officer has no more puzzling problem than supposedly "healthy" carriers of pathogenic organisms. These people are unfortunates. They have committed no offense, yet are a menace to the community in which they live and move.

For several years, an intensive study of diphtheria carriers has been going on in London, reports on which have been published from time to time.[1] The carriers from a number of hospitals devoted to the care of infectious diseases have been assembled in one institution for the purpose of this investigation. A general conclusion is that pathological conditions, or physical abnormalities in the upper respiratory tract, are the chief predisposing factors in causing or maintaining the carrier state.

Only those who harbored virulent diphtheria bacilli for at least 12 weeks were considered chronic carriers. The condition was considered as cured when 6 consecutive negative cultures taken at intervals of 1 week were obtained. The necessity of this prolonged examination was shown in a number of cases, which after giving negative results for even as long as 5 weeks, became positive, and remained so for long periods.

The throat carriers were those most easily cured. Of 60 cases treated by removal of tonsils and adenoids, 17 harbored the organisms in the throat only, and of these, 16 were cured. Of the remaining 43, in whom the organisms were harbored in the nose or ear also, only 19 were cured. The tonsil most apt to harbor the diphtheria organism is small, ragged, septic, and with deep crypts. It was found that by clinical examination the tonsils which on removal would give cultures of the diphtheria germ could be foretold. The experience gained from this study indicates that the best time for operation is from 6 to 8 weeks after the infection—earlier than usually advised.

Nasal carriers, who are difficult to cure, were treated by autogenous vaccines made from the diphtheria organism and complicating bacteria. In 3 cases, only the Klebs-Loeffler bacillus was used. Of 38 cases, 16 were cured in from 1 to 9 weeks, the others remaining positive, though some showed improvement. The staphylococcus was the most resistant and persistent organism. An alkaline nasal douche containing bicarbonate, chloride and biborate of sodium, approximately 2 grains of each to an ounce of water, had a very satisfactory effect, the mucous membrane becoming healthy, and cultures negative. Of 55 cases treated, 27 cleared up in from 1 to 7 weeks, 16 after one or more relapses, and in 12 the treatment failed. Spraying instead of douching was unsatisfactory.

In 2 out of 3 refractory cases, the antrum of Highmore was opened, and from 2, diphtheria bacilli were isolated. Removal of the tonsils and adenoids in 16 nasal carriers gave cures in only 3.

The ear carriers were the most difficult to treat, and no satisfactory procedure was discovered, though vaccines, removal of the tonsils and adenoids, mastoidectomy, and nasal douching were tried. In many cases of supposed ear carriers, the organisms were found to be saccharose-fermenting diphtheroids.

The health of carriers was usually found to be extremely good, and seemed to have little or nothing to do with the condition or its persistence. The most important carrier is the one who harbors the organism in the nose.

This study emphasizes the common mistake of speaking of

"healthy carriers." The late Dr. Nichols[2] laid stress on the fact that the carrier condition generally indicated an incomplete cure, with persistence of pathological tissue, which is borne out by the observations here recorded.

THE AWARD OF THE SEDGWICK MEMORIAL COMMITTEE

ACCORDING to the announcement made in the JOURNAL several months ago, the committee met at Minneapolis and considered the nominations which had been made for the Sedgwick Memorial Medal.

It was unanimously awarded to Charles Value Chapin, M.D., who has been the honored Superintendent of Health of Providence, R. I., for many years, and to whom all health officers look for enlightenment in health administration.

That the committee made a wise choice was proved by the universal approbation which its action received. The announcement was greeted with applause, and it can be said with certainty that throughout the land there will be no heartburning and no criticism of the committee's decision.

It was a matter of regret to everyone that Dr. Chapin's health prevented him from attending the meeting. The President with such members of the committee, and others whom he may select will make formal presentation of the medal at some time suitable to Dr. Chapin. We only wish that we could add to this demonstration by having every member of the Association present to assist in doing honor to Dr. Chapin on this occasion.

The Fifty-ninth Annual Meeting will be held in Fort Worth, Tex.

RESOLUTIONS

Presented by the Committee on Resolutions, William C. Hassler, M.D., *Chairman,* and adopted at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

I. AMERICAN INDIANS

WHEREAS, the American Indians are the most neglected racial group in the United States from the point of view of health protection; and

WHEREAS, Secretary of the Interior, Dr. Ray Lyman Wilbur, has requested appropriations adequate to provide for a reasonable degree of preventive and curative medical and nursing services for the Indian wards of the Federal Government, and sufficient to bring to an end the chronic undernourishment of many children in the Indian boarding schools, be it

RESOLVED, that the American Public Health Association endorses his request for appropriations for these purposes and respectfully urges upon the President of the United States, and upon the Committees on Appropriation of the Senate and the House of Representatives

of the Congress, the necessity of prompt and liberal provision of funds to prevent the further spread of preventable, and particularly of communicable diseases among the Indians, and to provide suitable and sufficient food for the Indian children.

II. TOBACCO AND TOBACCO PRODUCTS

Your Committee on Resolutions begs to present to you for your earnest consideration an endorsement of the bill recently introduced into the Senate of the United States by the Honorable Reed Smoot providing (a) For the inclusion of tobacco and tobacco products within the scope of the food and drugs acts. (b) For the amendment of the food and drugs act so that claims made for food and drug products in any advertising medium subject to interstate commerce control should be under the same strict regulation now applied to labels or other descriptive matter on, within, or around the container in which the products are packed.

III. WILLIAM H. DAVIS

WHEREAS, the death of Dr. William H. Davis, Chief Statistician for Vital Statistics of the U. S. Bureau of the Census, on January 8, 1929, deprived the American Public Health Association and its Section on Vital Statistics of a valued and respected member, therefore be it

RESOLVED, that the Association and the Section on Vital Statistics record their admiration for, and appreciation of the services of Dr. Davis, and their deep regret at the loss of one of the most active and sincere workers in his branch of public health work, and enter on the minutes of this meeting the following brief biographical note:

William Horace Davis was born at Holyoke, Mass., July 21, 1871. He began his higher education at Amherst and from there entered Harvard where he was graduated with the degree of Bachelor of Arts in 1893 and the degree of Doctor of Medicine in 1897. He was resident physician at Massachusetts General Hospital for one year, following which he studied in Vienna and other places in Europe.

In 1900 he began the general practice of medicine and continued until 1908 when he accepted the position of Vital Statistician for the City of Boston, in which capacity he served until 1916 when he assumed the position of Chief Statistician for Vital Statistics in the U. S. Bureau of the Census.

When he entered the U. S. Bureau of the Census the birth registration area consisted of 10 states and the District of Columbia. Due to his intensive and well directed efforts this area increased to such an extent that at the time of his death it included 45 states, the District of Columbia and the Virgin Islands. During the same period the death registration area increased from 26 to 45 states and from 70.2 per cent to 95.5 per cent of the total population.

Dr. Davis was recognized by his associates in American vital statistics as one of the foremost among those who have devoted their lives to the improvement of this important branch of statistical science. He was known internationally in his profession, and at the Conference for the third revision of the International List of Causes of Death at Paris served as Vice-Chairman, and was instrumental in bringing about many improvements in the list.

For many years he had taken an active part in the affairs of the American Public Health Association, especially in the Vital Statistics Section. He served as a Vice-President of the Association in 1923–1924, Chairman of the Vital Statistics Section in 1919–1920, and served as both Chairman and as an active member of important committees, both of the Association and the Vital Statistics Section.

Those who knew him will remember Dr. Davis as a modest, kind-hearted, conscientious, and lovable friend and colleague and as one who adhered to the principles of honesty and fairness at all times.

It is recommended that a copy of this resolution, together with the biographical note, be sent to the widow, Mrs. Mabel Johnson Davis, with an expression of the Association's sympathy.

IV. IN MEMORIAM

Your Committee on Resolutions respectfully brings to the attention of the members of the American Public Health

Association the following list of the deceased members and Fellows.

They fought as brave soldiers.
They have now been discharged.
Their warfare has ended,
And their treasures enlarged.

The memory of our association with them will linger and their names be inscribed on our rolls forever.

V. THANKS TO MINNEAPOLIS

The Resolutions Committee recommends that this Association give a hearty vote of thanks and appreciation to the citizens of Minneapolis for the generous hospitality extended to it through his Honor William F. Kunze, Mayor and Chairman of the Local Committee on Arrangements, Dr. R. O. Beard, Secretary of the Local Committee, and Dr. Francis E. Harrington, Chairman of the Entertainment Committee, and for the excellent arrangements for the Convention in its new auditorium for the meetings of the 58th Annual Convention. It is further resolved that this Association commends the Educational Exhibit and expresses its appreciation and thanks to the Local Committee who were responsible for the same.

VI. SCHOOL PHYSICIANS

Your Resolutions Committee recommends the endorsement of the following regarding a higher education require-

ment and a higher salary rating for school physicians:

WHEREAS, school physicians as a class have not heretofore been adequately prepared for the work which our complex educational systems now demand; and

WHEREAS, school physicians have not heretofore been paid a salary sufficient to justify this additional training and to enable them to devote their full time and best efforts to this work; and

WHEREAS, it has become necessary to take definite steps to improve this situation; therefore be it

RESOLVED, that the American Public Health Association does recommend consideration of and action upon, by the various states, the following minimum requirements for school physician applicants hereafter applying:

1. Graduation from an acceptable medical school, one year of acceptable internship and a license to practice medicine in the state.

2. Six semester hours of graduate training in medical subjects relating to school health work.

3. Six semester hours in a school of education of work embodying the principles of health education and the organization and administration of same.

4. This twelve hours of graduate work must be completed within three years after certification by the state board of education.

And that they further recommend:

1. The establishment of a salary rating equivalent to that now granted the high school principals in their respective localities.

2. That this salary be subject to automatic increase according to length of service.

3. And that it be subject also to an increase commensurate with educational merit and progressive professional development.

This resolution has been adopted by the American Association of School Physicians.

A. J. CHESLEY, M.D.

ALBERT J. CHESLEY, M.D., PRESIDENT

DR. Chesley, Secretary and Executive Officer of Minnesota State Department of Health, was elected President of the American Public Health Association at the Minneapolis meeting, October 3, 1929—the fifty-eighth in the long line of Presidents beginning with Stephen Smith, who served in that capacity during the period 1872–1874.

Dr. Chesley was born in Minneapolis, Minn., September 12, 1877. While still a young man he began his public health work—first as nurse in the Minnesota Soldiers Home Hospital; then, after service as a private in Company F, 13th Minnesota Volunteer Infantry, 1898–1899, as nurse in the Minneapolis Smallpox Hospital for 6 months during the epidemic of 1900. In 1901 he entered the medical school of the University of Minnesota; and upon graduation was appointed bacteriologist under Dr. F.

F. Wesbrook, Director of the State Board of Health Laboratories of Minnesota. In 1919, he became epidemiologist in the Division of Epidemiology, and in 1912 director of this division; in 1914 he became director of the Division of Preventable Diseases.

At the request of the American Red Cross Headquarters of Paris, Dr. Chesley was granted leave of absence for overseas duty from May, 1918, until October, 1920.

He was public health expert to the A. R. C. Commission to France, and in 1919 was sent to Poland to work under the Commissioner to Poland, later himself becoming Commissioner to Poland.

At present Dr. Chesley is secretary-treasurer of the Conference of State and Provincial Health Authorities of North America and a member of the Board of Directors of the National Society for the Prevention of Blindness.

SEDGWICK MEMORIAL MEDAL AWARD

THE first award of the Sedgwick Memorial Medal has been made to Charles Value Chapin, M.D., Superintendent of Health of Providence, R. I. This medal, established by subscription from friends and former students of the late Professor William T. Sedgwick, President of the American Public Health Association in 1915, is awarded for distinguished service in public health.

Dr. Chapin was President of the American Public Health Association in 1927, and is internationally famous for his work in the control of communicable diseases. Announcement of the award was made at the General Session of the Fifty-eighth Annual Meeting of the American Public Health Association in Minneapolis.

The formal presentation of the medal will take place on a later, appropriate occasion.

CHARLES V. CHAPIN, M.D.

NEW MEMBERS

Ida M. Alexander, M.D., A.B., Lansing, Mich., Lecturer, Bureau of Child Hygiene, State Department of Health

Walter C. Allen, M.D., Rochester, N. Y., Previously Assistant Surgeon, U. S. Public Health Service; no official public health position at present

Gladyce L. Badger, San Francisco, Calif., Nursing Field Representative, Pacific Branch Office, Red Cross

George H. Becker, M.D., A.B., San Francisco, Calif., Epidemiologist, Department of Health

Maharaj Mom Chow Bichitr, Bangkok, Siam (Assoc.)

Waldimar T. Browne, M.D., Ph.D., New Orleans, La., Assistant Health Officer

Laura A. Cauble, New York, N. Y., Chairman, National Conference Board on Sanitation

Lane B. Cooke, M.D., Dallas, Tex., Director of Public Health

Hulda A. Bieri Cron, Evansville, Ind., Director, Evansville Public Health Nursing Association and Health Center

Laurence A. Cushman, M.D., B.S., West Hartford, Conn., Health Officer and School Physician

James E. Davey, M.B., Hamilton, Ont., Chief School Medical Officer

Florence Erna, R.N., Martinez, Calif., Public Health Nurse

Laurence F. Foster, Ph.D., Berkeley, Calif., Chairman, School Health Committee

William J. French, M.D., New York, N. Y., Director, Division of Public Health, Commonwealth Fund

Fern A. Goulding, Ames, Ia., Instructor of Hygiene, Iowa State College

Robert Graham, D.V.M., Urbana, Ill., Chief, Division of Animal Pathology and Hygiene, University of Illinois

Allen C. Hutcheson, M.D., Houston, Tex., Health Officer

Mrs. Ruth S. Kase, Salem, O., Nurse, Board of Education

Homer R. Keyes, M.D., Los Angeles, Calif., Hygiene Physician, Department of Health

S. Adolphus Knopf, M.D., B.S., B.A., New York, N. Y., Consulting Physician, New York Department of Health

Dr. George W. LaBrier, Edinburg, Tex. (Assoc.)

Cassius T. Lesan, M.D., Mount Ayr, Ia., Member Iowa State Board of Health

Ferdinand McKeige, Brooklyn, N. Y. (Assoc.)

Ella E. McNeil, R.N., Philadelphia, Pa., Director of Health and Nursing, S.E. Pennsylvania Chapter, American Red Cross

Ethel M. Mealey, A.M., New York, N. Y., Staff Associate, Division of Health Education, American Child Health Association

Jerome Meyers, M.D., New York, N. Y., Medical Industrial Inspector, Department of Health

Luella Olson, R.N., Jefferson City, Mo., School Nurse

Mabel M. Oskins, R.N., Vincennes, Ind., Visiting Nurse

His Royal Highness Prince Paribatra of Nagara Svarga, Bangkok, Siam (Assoc.)

Peter E. Peterson, Woodbridge, N. J., Health Officer

Paul S. Prickett, Ph.D., Evansville, Ind., Chief Bacteriologist, Mead Johnson & Co.

BIBLIOGRAPHY ON INDUSTRIAL FATIGUE

A number of copies of the *Bibliography on Industrial Fatigue* are available in the Association Office. This is a supplement to Dr. Eugene Lyman Fisk's *Report* as Chairman of the Committee on Industrial Fatigue, which was presented at Third Session of the Industrial Hygiene Section in Minneapolis at the Fifty-eighth Annual Meeting of the A. P. H. A.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

The Effect of Closing and Fumigating Schools—The fallacy of closing and fumigating schools in attempting to control outbreaks of disease has been given considerable publicity in Pennsylvania. Definite information on how to control diseases in school by modern, effective methods has been described in *Pennsylvania's Health* published bimonthly by the Pennsylvania Department of Health, in *Hygeia* (April, 1929) and in the *Pennsylvania Medical Journal,* and in the *Pennsylvania School Journal.* Through these practically every physician, health officer, school principal and teacher is reached. But those who most need instruction do not read these articles, and in spite of all the appeals some local school or health officials order the closure and fumigation of schools. The desk of the writer receives from the newspaper clipping bureau notices of all schools which have been closed. No other report of such action by school boards is made to state officials.

Whenever it becomes known that a school has been closed because of contagious disease the local authorities are requested by the Department of Health to open the school immediately; institute daily examination of all involved classes at once and at the end of the incubation period; to exclude all suspects, to have all suspicious absentees followed and to report and to have quarantined all cases; and to abandon all fumigation and not to destroy any books.

The results of the closure and fumigation of schools are exactly what would be expected by public health authorities. Closing schools scatters the disease and fumigation does not control the infection. In 22 schools which depended upon fumigation only to stamp out their contagious diseases there was a total of 171 cases within a month before and just 300 within a month following the closure and fumigation. Fourteen schools attempted to check scarlet fever outbreaks with formaldehyde. Within a month before its use they had 91 cases of scarlet fever, and during the month following the fumigation 123 cases. Another rural school not included in the above summaries developed 4 cases of scarlet fever, closed and fumigated; then 4 more cases appeared, the school was again closed and fumigated; 7 more cases appeared and the school was again closed and fumigated, after which 23 more cases of scarlet fever developed. At that time the state first heard of the conditions; half of the cases had not been reported. The school principal wrote that " the school was closed January 21, February 4 and February 18 when the schoolrooms and halls were thoroughly wiped with a strong solution of Blank's disinfectant and then tightly closed and Blank's high power formaldehyde candles burned in them." The rooms and halls were well sprayed each evening after the last session with a strong solution of a much-advertised antiseptic. The state epidemiologist, quickly located 3 children with desquamating hands and the outbreak ceased.

Other diseases gave corresponding results when closure and fumigation were depended upon rather than personal examination of the children. Two schools with German measles had 32 cases before and 96 cases within a month after fumigating. Another school had 19

cases of measles before, and 30 after fumigating the entire building. Two with mumps had 13 cases before and 12 after closing. Another rural school used the same methods with diphtheria and had 3 cases before and 14 within a month after fumigating the building. A rural school in Bradford County with a few cases of measles closed, against advice, and the disease quickly spread to 2 other rural schools in an adjoining township, and when they closed, the infection quickly spread over the entire county.—Harold B. Wood, M.D., Epidemiologist, Pennsylvania Department of Health.

Review of Health Conditions in Syracuse—The Metropolitan Life Insurance Company has recently published for the General Federation of Women's Clubs a review of health conditions in Syracuse, N. Y., and a statement of the needs of that community. The appropriation of the department of health for the year 1927 was $1.28 per capita. This sum was further increased by 40c per capita from contributions of the Milbank Memorial Fund and the Budget of the Department of Public Instruction.

A timely and extremely readable résumé of the health work in Syracuse for 1928 will be found in the last annual report of the Milbank Memorial Fund.

Diphtheria Prevention in Philadelphia—The September issue of the *Monthly Bulletin* of the Philadelphia Department of Public Health contains the complete announcement of the second annual diphtheria prevention campaign now being inaugurated in that city. Included in the report are reproductions of cards and forms used for educational purposes.

LABORATORY

C. C. YOUNG, D. P. H.

AN OUTBREAK OF BOTULISM FROM HOME-CANNED BEETS

WILLIAM LEVIN, DR. P. H., FELLOW A. P. H. A.

Director, State Hygienic Laboratory, Portland, Ore.

ON THE night of March 8, 1929, Mr. I. C. G., aged 51; Mrs. I. C. G., aged 37; Mr. P. A. S., aged 50; and Mrs. P. A. S., aged 55; ate a meal at the home of I. C. G., The Dalles, Ore. At this meal were served meat loaf, mashed potatoes, lettuce salad with mayonnaise dressing, vinegar beets, bread and butter, and blackberry pie. Mrs. I. C. G. also ate some Jello.

About 16 hours later Mr. G. complained of dizziness and nausea. He vomited. Disturbance of vision became marked. Diplopia and paralysis of the tongue and muscles of the pharynx set in. Constipation was marked. He was first seen by Dr. Fred F. Thompson, The Dalles, on March 11, and he died on the same day. All the other persons who ate at the meal had eye symptoms, nausea, and vomiting, but recovered.

Of the foods eaten at the meal the

meat loaf (beef sausage) was bought at the family butcher shop, and had been baked sufficiently long enough to rule out bacterial infection. Mrs. G. stated that the loaf was off-taste. Other persons, however, had bought and eaten of the same beef sausage, and no cases of infection or poisoning had occurred. The beets were the only other food which could be suspected.

Mrs. G. had opened a quart jar of home-canned beets on March 8, and after pouring off about half of the liquid, had replaced it with vinegar. She stated that she detected a slight odor to the beets, and this was corroborated by her husband. Neither, however, thought much of it, and they ate of the beets at both the noon and evening meals. The beets had been canned by a neighbor late in the summer of 1928. They had been subjected to 3 hours of boiling in a kettle closed at the top, but not under pressure.

A portion of the suspected beets was recovered for examination. On opening the jar a distinct putrefactive odor could be noticed in spite of the rather marked vinegar odor accompanying it. Several of the beets were slightly soft, but in appearance were in no way abnormal. Another jar of beets obtained from the neighbor who had canned the beets was found to be normal in all respects.

One c.c. of the beet juice was fed to a guinea pig. Death occurred in 12 hours. Another guinea pig was fed with about 2 gm. of solid beet; death occurred in a little over 24 hours. Beef digest broth cultures were made from both the juice and solid beets. *Cl. botulinus* was obtained after 5 days' incubation from the juice culture only. (Through the kindness of Dr. Karl F. Meyer, University of California, the organism was identified as *Cl. botulinus*, type A.)

It is interesting to note that a hen fed with 3 to 5 gm. of the solid beet showed practically no symptoms of poisoning. Five c.c. of the beet juice fed the same hen about a week later also had no effect on her. Presumably she had developed sufficient antitoxin to protect her against a toxic dose. That the strain of *Cl. botulinus* present in the toxic beets was not a powerful toxin producer was evident, since there was only 1 fatality among the 4 cases, and it did not produce toxic symptoms in the hen. The patient who died had previously been under a physician's care for heart trouble.

It is doubtful whether the vinegar had any influence upon the toxicity of the beet or its juice, except in so far as it acted as a diluent. In an outbreak of botulism occurring at Albany, Ore., in 1924,[1] 12 persons, ranging in age from 18 months to 76 years, partook of a bean salad, and all 12 died. The beans were home-canned and were served with vinegar, cream and sugar.

Cl. botulinus is found in many of the soils of the Pacific Coast states. The spores of *Cl. botulinus* have been found in 31 per cent of the soils examined from Oregon, 80 per cent from Washington, and 29 per cent from California.

The outbreak at The Dalles is the seventh occurring in Oregon. Altogether there have been 21 cases and 17 deaths. All were caused by home-canned foods. Four outbreaks were traced to string beans; 1 to corn; 1 to turnips; and 1 to beets.

RECENT DEVELOPMENTS IN THE CONSTRUCTION AND OPERATION OF THE PHOSPHORUS ANAEROBIC JAR

PHILIP L. VARNEY

Department of Bacteriology and Immunology,
Washington University School of Medicine, St. Louis, Mo.

SEVERAL years ago the writer described a method for producing strictly anaerobic conditions by burning phosphorus within a tightly sealed glass jar containing the cultures.[1] While quite satisfactory for most purposes when operated as described, continued use of the jar has shown the necessity for certain changes in its construction and mode of operation, as described below.

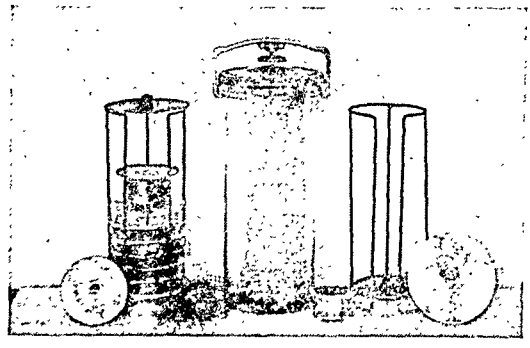
The use of galvanized steel or iron wire for the construction of the Petri dish holder, as recommended in the original article, has been discontinued, and either ⅛-inch monel or ⅝-inch brass rod substituted. While the commercially manufactured holder is constructed of monel, brass rod has been found to be more satisfactory and more easily worked when the apparatus is to be made in the laboratory, and is to be recommended for this purpose.

A disadvantage of the old type of frame was that after a period of use of from 6 months to 1 year, concretions of metallic salts formed on the metal, making it very disagreeable to handle, resulting eventually in the total disintegration of the frame. While a very small amount of metallic salts form on a brass frame after several years' continued use, these may be easily removed, and in no way detract from the strength of the apparatus. Monel frames are entirely resistant to the action of the phosphorus and its salts and from the standpoint of cleanliness and durability are superior to either iron or brass.

Because of the great variation in size of the standard 5 by 12-inch museum jars available, it has been found practical to make all frames small enough to fit inside the smallest jar encountered. A frame with an outside diameter of 11.2 cm. and a height of 26 cm. has been found suitable for all 5 by 12-inch jars now sold. The platform should be made 2.5 cm. from the bottom, as shown in Figure I.

Due to their direct contact with the phosphorus and its flames, and the resulting powerful chemical and physical action exerted upon them, the galvanized iron cup for holding the charge of phosphorus, and the gauze screen support originally described, are very short lived, and should be replaced by a monel cup 5 cm. wide and 3 cm. high, and ¼-inch mesh monel metal supporting screen 6 cm. in diameter and 4 cm. high. Because of the highly resistant character of such apparatus, the need for replacements is entirely obviated.

It has been found that when the apparatus is operated as described in the original article, due to the high moisture content within the jar the charge of phosphorus rather quickly becomes covered with water, so that no further oxidation could take place should a leak occur. Furthermore, when placed directly in a metal holder, the phosphorus burns but slowly. It is important, therefore, to protect the phosphorus from the action of these agents, which may be done by placing calcium carbonate (precipitated chalk) in the bottom of the phosphorus cup and tamping it firmly to a depth of about ½ cm. This bed of calcium carbonate acts as an excellent blotter, absorbing all of the excess moisture, and allowing a much more rapid oxidation of the phosphorus than before. It also acts indirectly as



a safety factor, since dry phosphorus will further oxidize on the least entry of oxygen through a poor gasket, thus keeping the atmosphere entirely devoid of free oxygen.

The tin or paper cover (F) described in the original paper should not be used, since it has been found that this leads to the condensation of a great deal of water in the plates, with a consequent increased possibility of contamination. The more satisfactory alternative is to place a sheet of 11 cm. filter papers between each of two Petri dishes, or several sheets above the test tubes, thus effectually protecting them from the deposit of phosphorus trioxide, or from an excess condensation of water.

The asbestos discs used to protect the jar from the action of the phosphorus flames have been somewhat modified, being made as shown in Figure I. A 2 cm. hole is cut in the center of the lower disc so that when the disc is placed in position over the phosphorus, this hole acts as a chimney, drawing a constant supply of fresh air over the burning phosphorus, increasing the rate of exhaustion of the oxygen. The heated air passes upward through this chimney and impinges against the upper disc placed on top of the frame, and thence back to the bottom of the jar. The convection currents very quickly bring the available oxygen to the point of oxidation, with a consequent decrease in the time necessary to produce anaerobiosis, and give a greater factor of safety, since but very little flame impinges on the glass walls of the jar.

The amount of water entering the tubes or inverted plates is usually negligible, but may be quite large in amount if the plates are left in the jar for long periods of time. The deposition of water may be almost entirely eliminated if a small amount of sodium chloride is placed in the water at the bottom of the jar. While this effectually prevents the condensation of water within the tubes or plates, it is disadvantageous to use this method for stock cultures or plates

FIGURE I

PHOSPHORUS ANAEROBIC JAR SHOWING PARTS, WITH A PLATE HOLDER LOADED AND READY FOR INCUBATION

incubated for long periods of time since it leads to the extraction of water from the culture medium, and a consequent decrease in viability of the cultures. While practically all of the common anaerobes may be kept for 6 months to 1 year on blood agar slants within the jar, the cultures die out in a very few months when salt is added to the water.

In selecting jars for use as anaerobic chambers, care should be taken to use only those with a heavy glass shoulder, sufficiently strong to withstand the pressure when the cover is tightly clamped on. Jars having weak shoulders will lead only to trouble through breakage and leaking.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

The Problem of Heart Disease—Heart disease in all civilized countries is the leading cause of death and of a vast amount of physical impairment. During the examination of men for the World War, 5 per cent were found with organic defects of the heart, and 90 per cent of these were rejected for service. The total of all organic diseases of the heart was 30.74 per 1,000 men, the range being from 68.84 for the state of Washington to 16.29 for Wyoming. In the U. S. Registration Area, 211,976 deaths occurred from all forms of cardiac affections during 1927. The death rate has progressively increased from 165.0 per 100,000 population in 1915 to 196.2 in 1927. The rate for pericarditis declined slightly from 1.1 to 0.9 and that from acute endocarditis from 9.1 to 8.2. The increases are shown by angina pectoris and other diseases of the heart.

In England and Wales the total death rate from heart affections increased from 161.7 per 100,000 population in 1917 to 183.5 in 1927. A slight decrease is shown by pericarditis, whereas acute endocarditis shows a small increase. In New Zealand the death rate from heart affections increased from 143.7 in 1918 to 156.4 in 1927. For the Commonwealth of Australia the figures also show a steady rise in the number of deaths from heart disease. Comparing the aggregate rates for the 4 countries, it appears that the United States has the highest rate for all forms of heart diseases for the year 1927, or 196.2 per 100,000, compared with 183.5 for England and Wales, 156.4 for New Zealand and 133.8 for Australia.

The mortality rates given for the U. S. Registration Area for 1925 show immense variations. Thus, while the average rate for 1925 for the Registration Area was 185.5, it was 216.2 for the cities and 159.5 for the rural portions of the registration states. It was as high as 262.2 for New York and as low as 83.1 for Idaho. At the present time no explanation can be offered for these variations, except that they depend to a considerable degree upon the age distribution of the population. A strictly scientific study of heart diseases on the basis of mortality data at the present time is practically impossible. The unfortunate classification of "other diseases of the heart" is too large to justify definite assumptions as to the increase or decrease in particular forms of heart impairments.—Frederick L. Hoffman, *Spectator*, 123: 3, 23–25 (Aug. 29), 1929.

Bovine Tuberculosis in Children—A study of the incidence of bovine infection in children has been carried out for the past 3 years, in the Toronto district, under the auspices of the National Research Council of Canada. From a group of 168 children all under 14 years of age, a total of 190 strains of tubercle bacilli were recovered. Of the 190 strains identified, 160 which were recovered from 148 children proved to be of the human variety, and 30 strains recovered from 20 different children were of bovine origin. The oldest of these 20 patients was 12 years of age, and the youngest an infant of 5 months.

In the great majority of the cases from which the human type of bacillus was recovered, a history of contact to open tuberculosis was obtained, and in a certain proportion of the surgical cases, there was evidence of tracheo-

bronchial or pulmonary tuberculosis demonstrable on physical examination or x-ray. All these children reacted to tuberculin. In 65 cases of bone and joint tuberculosis, 63 were of the human type and 2 of the bovine type; in 32 cases of tuberculous meningitis, 31 were of the human type and 1 of the bovine type; and in 16 cases of tuberculosis of the lymph nodes, 4 were of the human type and 12 of the bovine type.

All the children with the bovine type of tuberculosis came from districts where pasteurization of milk is not carried out. None of the children, with the exception of 1 case, showed evidence of pulmonary or tracheo-bronchial tuberculosis. The evidence pointed to the alimentary routes of infection. From this study it appears that bovine tuberculosis is a factor in childhood infection in rural Canada, and in unpasteurized areas. Tissue localization of the bovine tubercle bacillus is peculiar in certain regions, the lungs being practically immune.—R. M. Price, *Canad. Pub. Health J.*, 20: 323–330 (July), 1929.

Economic Status and Incidence of Illness—This is the tenth morbidity study in the series carried out at Hagerstown, Md., by the U. S. Public Health Service. The survey was begun in the autumn of 1921. Approximately 1,800 households were visited, and classified in groups ranging from well-to-do to very poor. The usual association of crowding with economic status was observed, the average number of persons per room being 0.43 for the well-to-do, as against 1.18 for the very poor. A consistent association of illness incidence and economic status was indicated.

During the period December 1, 1921, to March 31, 1924, the well-to-do and comfortable group combined had an annual illness rate of 991 per 1,000 persons, as compared with 1,068 for the moderate group and 1,113 for the poor and very poor groups combined. Some general associations were noted between specific illness and economic status. Influenza and grippe rates ranged from 123.7 per 1,000 persons for the well-to-do to 149.0 for the poor; rheumatism showed a rate of 13.6 for the well-to-do and 21.4 for the poor group; headaches, nervous conditions, and accidents showed similar variances.

The commoner infectious diseases, diseases of the circulatory, digestive and eliminatory systems, showed no correlation with the economic status. Association of illness with economic condition is differently manifested for infants than for adults. For children under 4 years of age the illness rates from all diseases varied from 1,817 per 1,000 for the comfortable group to 1,554 for the poor group; for the 10 to 14 year group the rates varied from 1,263 for the comfortable to 1,179 for the poor; whereas in the older age groups, higher rates were found among the poor than among the comfortable. For ages under 4 influenza gave an illness rate of 131 per 1,000 for the comfortable and 99 for the poor, as against 151 for the comfortable and 172 for the poor in the 25 to 44 year group. The rates for infectious diseases, particularly whooping cough and chicken-pox, were higher among children of well-to-do parents than among poor children.

The proportion of all cases attended by physicians was 70 per cent in the well-to-do and comfortable groups, as compared with 43 per cent in the poor group. However, for diseases of the nervous system, non-venereal diseases of the genito-urinary system, diseases of the bones and organs of locomotion, and the general diseases, the proportion attended by physicians was as great among the poorer families as among those of higher economic status. The results of this study show that the illness rates as observed were higher for the poor than for those economically better off, and in general, those families

which were definitely better situated economically had more medical attention than the remainder of the population.—Edgar Sydenstricker, *Pub. Health Rep.*, 44: 1821–1833 (July 26), 1929.

Late Results of the Manitoba Epidemic of Poliomyelitis of 1928—A late analysis of the data concerning the Manitoba poliomyelitis epidemic of 1928 shows that of 272 cases concerning whose present or recent condition it has been possible to obtain data, 143 had completely recovered and 128 still showed some degree of paresis or paralysis. The total number of deaths attributable to the epidemic was 40. In April, 1929, a report of 161 cases made by the Medical Research Committee of the University of Manitoba showed the results of convalescent serum therapy. Of the 161 cases, 69 treated with serum in the pre-paralytic stage made a complete recovery, as compared with 7 cases treated after the onset of paralysis.

More recent data were available concerning 117 of the 161 cases dealt with in the earlier report. These results concern the condition of patients from the epidemic at least 6 months after partial or complete recovery from it. Of the 60 cases treated with serum in the pre-paralytic stage, 54 or 90 per cent appeared to have completely recovered shortly afterwards, and 52 maintained this condition. These late results confirmed the conclusions in the previous report as to beneficial treatment of convalescent serum when given in the pre-paralytic stage. Of 6 cases treated with serum in the pre-paralytic stage and subsequently developing paresis or paralysis, 1 showed a delayed complete recovery. Of 16 treated with serum after the onset of paresis or paralysis, 3 showed a delayed complete recovery, and of 32 untreated with serum, 10 showed a delayed complete recovery. These of course do not include earlier recoveries. The 5 cases treated with convalescent serum in the pre-paralytic state, which showed at the time of the earlier report some degree of paresis or paralysis, showed definite improvement in the recent follow-up. Eleven of the 13 who received serum after the onset of paralysis and still showed paralysis were improving. The same was true of 17 of the 22 untreated cases still showing paralysis. The majority of the cases exhibiting improvement were being given the recognized orthopedic treatment.

Recent data concerning 83 of 158 cases in another series were also available. In this second group, it was uncertain whether serum was given in the pre-paralytic stage or later. The conclusions were in general agreement with the group of 117 cases. All of the 6, and 23 of the 35 cases now exhibiting paralysis, in the groups who respectively did and did not receive serum, show definite improvement. The majority of these cases were also receiving orthopedic treatment. In the remaining 75 cases only a present report was obtained. Of these, 27 reported complete recovery, 45 had present paresis or paralysis and 3 deaths were reported subsequent to the earlier report. These findings show the beneficent effect of convalescent serum treatment when given in the pre-paralytic state.—Mary McKenzie, *Canad. M. A. J.*, 21: 291–294 (Sept.), 1929.

Mortality in Amsterdam, Holland—A report of the Amsterdam Bureau of Vital Statistics for 1928 shows that the birth rate, inclusive of stillbirths, was 18.8 per 1,000 population. Of the 13,530 live births, 586 died during the first year of life. This gave an infant mortality rate of 43 per 1,000 live births. There were 40 deaths from measles during 1928, as compared with 99 during 1927. Scarlet fever prevailed as an endemic disease but caused only 6 deaths. There were 48 deaths from

whooping cough. This disease was especially prevalent among children under 1 year of age, the mortality in this group being as high as in the 1 to 4 year group.

Diphtheria caused 22 deaths during the year. The fatalities from influenza were reduced from 186 in 1927 to 118 in 1928. There were 421 deaths due to pulmonary tuberculosis, and 938 due to malignant tumors. The puerperal mortality rate was 4.6 per 1,000 live births. There were 19 cases of puerperal fever. —*J. A. M. A.*, 93: 786 (Sept. 7), 1929.

The Birth Deficit in Germany—Before the War, the German Empire, with average annual totals of 2,000,000 births and 1,200,000 deaths, had an annual excess of births over deaths of about 800,000, or from 12 to 14 per 1,000 population. In 1927, there were 1,160,000 births or 18.3 per 1,000; 757,000 deaths or 12.0 per 1,000, and an excess of births over deaths of 403,000 or 6.4 per 1,000, which is about one half the pre-war status. However, this can be accounted for by the peculiar distribution of age groups. According to an analysis freed from the accidental data of the distribution of age groups, the death rate is 17.4 per 1,000 population as against 12.0 per 1,000 under the unadjusted computation.

The readjusted birth rate is not 18.3 but 15.9 per 1,000. Instead of an excess of births over deaths, this shows a deficit of 1.5 per 1,000 population, which is 10 per cent below the figure needed to keep the population stationary. The birth deficit in Berlin is 57 per cent, and the average birth deficit of the large cities of Germany is 42 per cent, as compared with 31 per cent for such metropolitan centers as Paris and London. The rural regions occasionally show birth rates in excess of the minimal requirement for the preservation of the population.—*J. A. M. A.*, 93: 473 (Aug. 10), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Feeding Chlorine Through Long Pipe Proves Satisfactory—At the Chain of Rocks Plant of the St. Louis Waterworks, the difficulty of transporting chlorine cylinders from the unloading floor to the chlorinators, a distance of 800 feet, led to the conveying of the chlorine by a pipe. Batteries of 8 cylinders each are connected, on the unloading floor, to manifolds, which in turn are connected to a ¾-inch galvanized pipe leading to the chlorinators. This passes through a pipe gallery where the temperature is always low. At first trouble was experienced with liquefaction. When a new battery of cylinders was turned on, the high pressure resulting from the low temperature caused the chlorine to spurt from the control valve, which soon clogged. This was remedied by installing a reducing valve on the long line and maintaining a pressure of less than 100 pounds per square inch. All liquefaction trouble has been overcome.—A. V. Graf, *Eng. News Rec.*, 24: 102, 1929. (From papers of Water Pollution Research Board, England.)

The Development of Water Supply After the War—After the war, water works in Germany suffered from lack of material, strikes, and depreciation of money value. Building was almost impossible though Wiesbaden rebuilt its water works by using unemployed labor. After the stabilization of the Mark other cities, for example Hamburg, proceeded with building and extension work. The removal of water works from state control to companies has been a great incentive to progress and economy. Taking into account the general depreciation of money values, water in most towns is cheaper than before the war. Works built after the period of inflation, however, are in a different condition and prices are often very high.

Many towns endeavored to raise the standard of their water after the war and ground water was largely substituted for river water. So-called "ground river water," i.e., water from wells sunk in the valley of a river and gathering the naturally filtered river water, has been used. At Wiesbaden this proved unsatisfactory and had to be treated with chlorine and ozone, and a supply of artificial ground water, water drawn from the river and treated, has been substituted.

Several epidemics of typhoid broke out and, though they were mainly due to fortuitous combinations of unfavorable circumstances, they led to more careful considerations of water works conditions.

Treatment with chlorine has increased since the war. Slow sand filtration has been largely abandoned, rapid filtration with subsequent chlorination being substituted. Water softening is also more practiced than formerly, especially owing to the growth in the use of high pressure boilers. Corrosion and incrustation of pipes has been investigated and the best means of prevention found in treatment of the water. Piston pumps are being largely replaced by rotary pumps.—E. Grosz, *Ztsch. f. Kommunalwirtschaft,* 8, 19: 460, 1929. (From papers of Water Pollution Research Board, England.)

Technical Progress in Water Works Management—The article gives examples of progress in water works management after the war. The great aim is to replace small water works with great central supplies providing water for larger areas. Such systems are being prepared in Middle Saxony and for supplies from the South and East Harz valley dams, which serve the purpose of the English storage reservoirs in supplying a very greatly increased summer need. It is also intended to use surface waters to increase and enrich ground water supplies.

In water preparation rapid filtration is quickly superseding slow sand filtration. Treatment with lime water for de-acidification and with chlorine for bacteriological purification have increased largely.

Control of operation by a works laboratory, which in the case of small works could be used in conjunction with neighboring works, is important.

Electric working of pumps either fully or partly automatically controlled is being more and more adopted. The general type of valve is the wedge-shaped but under special circumstances ball valves are being applied. These in some cases include in their casings instruments for measuring and recording the flow.

Lately ferroconcrete pipes have come largely into use. These consist of a thin sheet metal jacket reinforced inside and outside with ferroconcrete. De-acidifying of the water is especially important when such pipes are used. With main pipe lines special devices against flooding, with automatic or semi-automatic working, are installed. Emergency repair services for night

work or times of frost are essential. Movable indicators are used for showing defects, a simple type being the geophone, a highly sensitive drum with weight-stretched membrane.

For the welfare of the workers it is advisable for large works to procure the services of a safety engineer.—Vollmar, *Ztsch. f. Kommunalwirtschaft,* 8, 19: 467, 1929. (From papers of Water Pollution Research Board, England.)

Examination of Swimming Baths—In 1926 the two filter plants for the Munich public baths were replaced by one for which the same chlorinating plant served. Experiments and observations were carried out on the condition of the water and the effect of filtration and chlorination.

Condition of the Water. Chlorinating removed the smell which, though the water itself appeared odorless after 14 days' retention, had been previously noticed in the building. Kisskalt's method for estimating turbidity gave satisfactory conditions of clarity after 14 days' retention period. The pollution of the bath by bathers is discussed and details of different analyses before and after use are given. Chloride content generally varied, nitrates increased more or less substantially, dissolved organic matter seemed to show little change though when estimated by its chlorine combining power it rose definitely. Comparative analysis in the case of the Munich baths was difficult, for the water is drawn in varying proportions from two differing sources. Chemical and physical measurements of turbidity are more useful in estimating purity than chemical analysis of dissolved matter but the latter, especially in the case of nitrogen-containing matter, should not be neglected.

Chemical condition corresponds to a large extent to appearance but this is never the case with bacterial condition. In the first 2 or 3 days after a new filling the germ-count grows while the water remains clear, then it sinks and remains low while the water becomes more turbid and deteriorates chemically. The germ count therefore does not serve as a measure of impurity but it is useful to test the working of filtration and chlorination.

The danger of infection by bath water is very slight and is to be judged not by germ-count but by estimation of coli-titer. A knowledge of the health conditions of the city is necessary in estimating the possibility of danger.

Effect of Filtration. A Bamag filter, 870 mm. deep with graduated filling, varying from 20–30 mm. to 0.1–1 mm., is used. The bath is refilled every 14 days and has a daily fresh water addition of 5 per cent of its content. Filtration was found to remove 71 per cent of suspended, 74 per cent of organic and 50 per cent of inorganic matter. Experiments showed that a rapid flow-through had no effect on the bacterial count while very slow flow caused turbidity in the bath; therefore a flow of 75 cm. per hour, or 3.4 cm. through 1 square meter of filter per hour, was chosen, whereby the germ-count was decreased 50 per cent.

Effect of Chlorination. The Bamag direct process is used. The chlorinated water enters the bath continuously through numerous small holes in a pipe across the width of the bath floor. By a comparison of chlorine additions in various baths, Lemmel found that the amount rose almost proportionately to the number of bathers. To make the chlorine excess sufficiently strong to remove danger of infection in the bath itself requires an excess of 0.3–0.5 mg. per liter, which is unpleasant to the bathers and, by dissolving out organic matter from the filter, renders the water turbid. Hamburg meets the difficulty by a large dose of chlorine and then clearing the water with aluminum sulphate before filtration, but this must

cost considerably more than simple filtration. Lemmel and Olszewski demand in the swimming bath water an excess detectable by benzidin but not by zinc iodide starch reaction. This amount, however, affects filter working and leads to turbidity. When this excess was detectable in the flow-off, the author found chlorine smell over the filter and sometimes in the bath hall and some turbidity towards the end of the 14-day filling period. Bacterial count decreased but as this is not a criterion of purity and *B. coli* was as effectively removed by a lower chlorine dose, the chlorination used by Munich is only strong enough to give a definite excess in the entering water (0.35–0.4 mg. per liter) but not to be constantly positive to benzidin reaction at the flow-off.

References to literature on the subject are given.—H. Ilzhofer, *Gesund. Ing.*, 32, 51: 513, 1928. (From papers of Water Pollution Research Board, England.)

Economic Significance of Malaria to an Industrial Concern: A Railway—Recognizing the importance of determining in so far as possible the economic loss due to malaria in an area prior to recommending expenditures, this article describes the result of such a survey in one of the important districts in which the E. B. Railway operates in India. The summary given by the author briefly describes the type of survey made and the determinations, and is here quoted:

(1) A brief description of the physical features of the Lalmanirhat district of the E. B. Railway together with its malarial distribution has been given; (2) the district comprises areas of varying physical features with different degrees of malarial incidence; (3) the number of cases of malaria and the number of cases of all other sickness in the district for the three years 1924, 1925 and 1926 are given for comparison; (4) the number of days lost to the Railway on account of malaria amongst the staff is given, and this is compared with the number of days lost from all other sickness; (5) the monetary value of the number of days lost from malaria has been estimated for the three years 1924, 1925 and 1926 and this has been shown to be not a negligible amount; (6) what percentage of the loss from all sickness does malaria alone contribute? This has been calculated and incidentally the anti-malarial measures started in 1925 have been shown to have been effective in reducing the loss due to malaria from 43 per cent in 1924 and 50 per cent in 1925 to 35 per cent in 1926.

Three graphs and accompanying tables are included indicating the influence of malaria on total cases of sickness and days lost through illness of railway employees in the Lalmanirhat District.—C. R. Rao, *Indian M. Gaz.*, 63, 10: 568–573 (Oct.), 1928.

Rat-flea Survey of the Port of Norfolk, Va.—This report is one of a series of reports of rat-flea survey work done by the U. S. Public Health Service at various United States ports for the purpose of obtaining and recording data that might be useful in determining the bubonic plague hazard at such ports.

The fact that some United States ports have had bubonic plague infections while other large and busy seaports have escaped lends value to such data. An hypothesis for this condition which has been suggested is referred to as well as observations in India relative to *Xenopsylla cheopis*, which is the predominating rat flea in certain parts of that country. Mention is made of the view held by some authorities that *Xenopsylla cheopis* is the only flea that need be considered in the transmission of plague from rat to rat under natural conditions and of the *Xenopsylla cheopis* index as the measure of infectibility of any community. By *Xenopsylla cheopis* index is meant the average number of *Xenopsylla cheopis* per live rat in the locality under consideration.

The report discusses the methods employed in the rat-flea survey at Norfolk, the distribution of rats, the distribution of fleas, and includes a comparison of

the results with similar studies at other United States ports. Tables containing the above data as well as data for other ectoparasites encountered are included.

The conclusions of the report are as follows:

Upon the basis of the findings of the 12 months included in the period of this survey, it is evident that *Xenopsylla cheopis* is the predominant rat flea in Norfolk for 8 months of the year.

The *Xenopsylla cheopis* index (2.56) of Norfolk seems sufficiently high to warrant the sanitary authorities in considering the port as probably infectible with plague, and the port should be diligently guarded against the introduction of plague, especially during the warmer months of the year (June 1 to December 1). It appears that conditions in the city are highly favorable for the perpetuation of the rat genus and that Norfolk has, at least, the average density of rat population that prevails in most cities of the Atlantic seaboard.—

H. E. Hasseltine, *Pub. Health Rep.*, 44, 11: 579–589 (Mar. 15), 1929.

The Bacteriological Control of Shellfish—The bacteriological control of shellfish is one of importance because of (a) the preference of shellfish for localities where the density of the sea water has been reduced by admixture with fresh river water; (b) the presence of sewage in nearly all rivers; (c) the addition by enteric cases and carriers of the causal organism to such sewage; (d) the fact that shellfish are frequently eaten uncooked.

Two methods commonly employed in the examination of shellfish for *B. coli* are Houston's and Klein's. Both methods are described briefly in the article. Houston's *B. coli* standards for oysters are: strict standard = 100 *B. coli* per oyster; lenient standard = 1,000 *B. coli* per oyster.

Another method employed by Prof. Eyre (London) consists of using 0.2 c.c.m. of the mixed shell fluid and minced flesh from each of 10 oysters picked at random from a batch. If *B. coli* are absent in this volume the oyster is regarded as "clean." Oysters are allowed to be sold only where 60 per cent or more in a batch are clean.

The author of this article is concerned chiefly with the examination of mussels and uses essentially the method of Klein. Comparison with the results of other bacteriologists and with different methods reveals certain discrepancies resulting from the following causes: (1) Errors in technic; (2) alteration in the mussels due to delay or conditions of transmission to the laboratories; (3) errors in sampling.

The third cause is considered most important and responsible for most of the discrepancies in that there is a chance for a wide variation in the selection of mussels for examination and in the selection of the particular fraction of mussel fluid to be examined. For the above reasons Klein's method is criticised with the recommendation by the author of another method, as follows: That 0.5 c.c.m. of the mixed fluid from the mussel is added to 4.5 c.c.m. of sterile saline, yielding a 1 to 10 dilution. Of this 2 c.c.m. are added to one tube of lactose bile broth, 1 c.c.m. to a second tube and 0.2 c.c.m. to a third tube. A positive result in the respective tubes indicates 100 *B. coli* per mussel, 200 *B. coli* per mussel and 1,000 *B. coli* per mussel corresponding to the strict, moderate, and lenient standards. The strict and lenient standards are the same as those of Houston's and the moderate the same as Klein's. Application of the author's test in actual practice is also explained briefly.—J. W. Bigger, *J. State Med.*, 36, 11: 638–641 (Nov.), 1928.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Thirty Years' Experience of Industrial Maladies.—After 27 years as Senior Medical Inspector of Factories, the author is amazed at the progress which has been made. Especially noticeable is the progress in illumination and locally-applied exhaust ventilation. In 1899, only 2 of the 23 white lead works had a vestige of exhaust ventilation for the removal of dust. So it was, too, in the 866 brass foundries in Birmingham, England, when the author visited them in 1903 on the request of those suffering from brassfounders' ague. Now every white lead factory is equipped with a system of locally-applied ventilation, and the conditions in brass-casting workshops are vastly better. But more important than that is the spirit of invention in the trades themselves in the discovery of labor-saving devices.

Throughout these lectures I shall lay stress, as a kind of test, on three axioms which experience has led me to enunciate. They are: (1) Unless and until the employer has done everything, the workman can do next to nothing to protect himself. (2) If you can bring an influence to bear external to the workman (i.e., one over which he can exercise no control) you will be successful; and if you can't, or don't, you won't. (3) All industrial lead poisoning is due to the inhalation of dust and fumes; and if you can stop their inhalation you will stop the poisoning. It is not due to dirty hands (i.e., eating with unwashed hands).

Examples of the influences I have in mind are:

(1) Prohibition, e.g., by the substitution of sesqui-sulphide of phosphorus for yellow phosphorus (effected by the Berne Convention).

(2) Conversion of pulp white lead into oil paint ready for the market in automatic closed-in machines without dry grinding.

(3) "Low solubility glaze" in pottery manufacture, by which the same amount of raw carbonate of lead may be used, but so combined in calculated quantity with siliceous material in a "frit" as to be practically insoluble in the gastric juice.

(4) Plastic rubber, that is, rubber in which lead oxide has been incorporated in a "mother batch" to the extent of 90 per cent, thus abolishing production of lead dust in later processes (first put into practice by Mr. C. A. Klein, Chemist to the Associated Lead Manufacturers, Ltd.).

(5) Disinfection of anthrax-infected wool by formaldehyde—the Duckering process—as carried out in the Government Wool Disinfection Station (Home Office), Liverpool; and finally, though not quite so successfully,

(6) Locally-applied exhaust ventilation by a fan.

Examples of influences, useful up to a point, but no remedy, which are not external, but depend on the will or whim of the worker to use them, are respirators, gloves, goggles, washing conveniences and waterproof sandpaper.

The statistics of notifiable diseases were in a state of chaos, so that detailed figures did not commence until 1900. It was necessary to see that no case of lead poisoning was included more than once in each year—second notifications being probably due to relapse or incomplete recovery from the first attack. A defect in the system is that notification by the medical practitioner has to be made to a layman. It was a fortunate accident that Sir A. Whitelegge was a medical man. Generally speaking, any symptoms necessitating absence from work and appeal to a doctor for treatment constitute sufficient grounds for notification. The slow onset of these insidious, industrial maladies, in which the patient passes through

a stage of absorption, does not amount to poisoning.

The principal results achieved from notification in the case of 11 notifiable diseases and poisonings for the years 1900 to 1928 inclusive, are shown in a chart, after which are taken up in some detail the subjects of mercury, arsenic, and phosphorus poisoning, anthrax infection, toxic jaundice (trinitro-toluol poisoning), skin cancer, chrome ulceration, aniline and carbon bisulphide poisoning. Of chronic benzol poisoning only one case has been notified.

Concerning skin cancer in mule spinners the author quotes Twort, working in Manchester, to the effect that " the carcinogenic activity of an oil is much reduced or completely removed by extraction with sulphuric acid or by oxidation and by reduction." About 9 cases every month of skin cancer occur among the 33,000 mule spinners in Lancashire. The percentage of deaths is low—not 3 per cent among patent fuel workers (from skin cancer), about 9 per cent among tar distillers, about 33 per cent among cotton mule spinners, and over 47 per cent among retort house and pitch diggers in gas works. The reason for these differences, in the author's opinion, is that only a fraction of the cases is being reported in tar distillers and gas workers, while nearly all are reported among patent fuel and shale oil workers. The salient feature about skin cancer is that not 5 per cent begin to show the malady under 30 years of age, while the average age for contraction is about 52 years. Likewise, less than 3 per cent show the disease in dangerous form under 20 years' duration of employment, while the average exposure is approximately 40 years. " Periodic examination, therefore, should be limited to mule spinners aged 40 or over and with a duration of employment of 30 years." In compensation for deaths alone the cotton industry must anticipate paying 10,000 pounds a year until it realizes the value of periodic examinations twice yearly. Dr. Henry has gone a long way to prove that the incidence of skin cancer among the mule spinners results from the gradual change-over in the " sixties and seventies " from animal and vegetable to mineral oils, for the purposes of lubrication. —Sir Thomas Morison Legge, late H.M. Senior Medical Inspector of Factories. *J. Roy. Soc. Arts,* 4006: 1007–22 (Aug. 30), 1929.

The Organization of Treatment of Accidents and Diseases among Workers of Rand Mines—The gold mines under the control of the Central Mining Rand Mines Group, Witwatersrand, Transvaal, compose 14 gold mines, employing approximately 85,000 natives (Negroes of the Bantu race), and 10,000 Europeans. The depths of the workings vary from nearly 2,000 to nearly 8,000 feet below the surface of the ground. The average elevation of Witwatersrand above sea level is about 5,600 feet; thus the deepest mines reach a depth of about 2,000 feet below sea level. The actual mining is carried out with drills, using compressed air, and the blasting is done with great quantities of gelignite owing to the hardness of the strata, which are rich in silica. For the latter reason large quantities of water are used to keep down the dust, but this results in a saturated humidity. Temperature increases approximately 1° F. for every 200 feet of depth so that that of the deeper workings is high, and combined with a high humidity, necessitating potent ventilation to render working conditions possible. The natives are housed and fed by the mines, but supply their own clothing.

It is a part of the legal obligation of mine owners to provide the natives with free medical treatment for both diseases and injuries; also to provide

hospital accommodations equivalent to 2½ per cent of the number employed, as well as a sufficient number of full-time medical officers. Thus there are 3 central native hospitals having 1,264 beds; 4 other hospitals with 668 beds; and 7 clearing hospitals or dressing stations with approximately 415 beds. Both European nurses and native girls trained as nurses are employed.

On returning from work every native is inspected by a native watchman for injury or sickness, and for any such he is immediately conducted to an ambulance room where his medical care begins. A very elaborate organization has been built up for dealing with accidents; also a first aid training system. A considerable number of the Europeans and over 2,000 natives possess certificates in first aid (the equipment is described in detail).

The number of accidents is large and the medical staff can fairly be said to be highly expert in the treatment of same. For example, in the treatment of penetrating wounds of the knee a standard method has been devised:

> which has given surprisingly good results, consists of excising badly damaged tissues, if necessary widening the opening, washing out the joint with ether, applying a preparation known as Bipp, which is a bismuth, iodoform and soft paraffin paste, and closing up the wound. Light passive movement is started within a day after the operation, and continued with gradually increasing range. When the patient is able to walk about, apparatus intended to increase the range of motion is used. The one most commonly employed is in the form of a stationary bicycle, which the patient pedals against resistance offered by an adjustable brake band.

The most serious disease is pneumonia, the number of cases of which is very high although the case mortality is low, 12.29 per cent for the year 1927. The natives are also very prone to tuberculosis. Last year 529 cases of the pulmonary form were admitted to the hospitals with a case mortality of 62, or 11.72 per cent. This does not, however, include those sent home who were able to travel. It is admitted that in spite of the large amount of material no important contribution has so far been made to the therapy of either pneumonia or tuberculosis.

Hookworm disease infects some 60 per cent of natives recruited from Mozambique, and 20 per cent of those recruited in South Africa, but it is very rare to find any clinical symptoms of the disease among natives. The majority of natives arriving at the mines are suffering from vitamin deficiency, particularly of the antiscorbutic vitamin, with a tendency to hemorrhage from the gums and into the joints and muscles, as well as easy ulceration at the sight of slight injuries. On this account the diet of natives has been specially arranged to combat this condition of scurvy.

The medical service for European workers is elaborate. They receive half their average earnings when incapacitated by sickness or injury; medical attendance for themselves and members of their families for sickness, injury, and maternity; funeral expenses similarly; a lump-sum compensation for any disability sustained, and likewise to the estates in the case of death. Beyond this, some 12,000 pounds per annum are raised and expended voluntarily for the surgical treatment of serious accident cases. The employee is given wide choice of attending surgeons, while specialists are available for any case requiring them. In the past year 622 Europeans were given surgical attention for injuries at an average cost of 2.027 pounds per patient.

All employees undergo a routine physical examination which, in the case of natives, may include a radiographic chest examination. Each native is reexamined at intervals of not more than 6 weeks. About one third of the Euro-

pean applicants are rejected for employment, and the balance must be reexamined every six months. On the first detection of silicosis, one is warned. If any signs of tuberculosis are detected, he must cease employment as a miner. If the worker with beginning evidences of silicosis elects to retire, he is given a lump sum of 375 pounds or more, depending on his average earnings. Advanced stages of silicosis and silicosis with tuberculosis are given a life pension, to which the widow and children are also entitled.

At the central rescue training stations skill in the use of oxygen-breathing rescue apparatus is required, as well as in the use of Burrell All Service Gas Mask, and the methods of detecting CO underground. The writer is head officer of the medical organization described. —A. J. Orenstein, M.D., *Opera Collecta,* Fifth International Medical Congress on Industrial Accidents and Occupational Diseases, Budapest, 1929, pp. 475–483.

Perforation of the Nasal Septum in Chromium Workers—The affliction noted occurred among chromium platers using an electrodeposition: a fine mist rises aboves the process composed of chromic acid particles which may affect the skin or cause ulceration in the nose. (A review of the literature is cited.)

A series of 18 cases is here reported. In 2 workers, complete perforation of the nasal septum with openings ¼ inch in diameter were found after only 6 weeks' exposure. The process is painless; an irritated feeling is experienced when the worker first comes into contact with the fumes. It is not disabling. Most of the workers were unaware of the perforation. Bleeding was not severe and this only when the crusts were forcibly expelled. The sense of smell was impaired in only one case. Difficulty of breathing was not encountered save when crusts blocked the passage ways. In all cases the perforation was limited to the cartilage portion of the septum and at its posterior part. Hence the shape of the nose was never affected.

The first symptoms experienced upon entering the chrome room were sneezing and a burning sensation in the nose. After a few days bleeding was encountered, followed by crusting. A whistling sound during breathing was noted in the majority of cases when the perforation was small.

Protection of the workers is effected by a strong lateral suction in which the air velocity should be 2,000 feet a minute. Air velocity should be measured by a kata thermometer. The fumes being heavy should be withdrawn laterally (and downward). Proper ventilation of the nature described prevents the irritation.

In treatment, employees must be warned not to pick at the nose, the nurse should check up daily all cases of irritation, and ordinary plain vaseline to the septum causes all unpleasant symptoms to disappear.—Fred W. Dixon, M.D., *J. A. M. A.,* 93, 11: 837–38 (Sept.), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Green Tea as a Source of Vitamin C—Green tea has recently been reported as a rich source of Vitamin C. Miura and Tsujimura, the first investigators in 1924, reported that an infusion from a gram of green tea prevented scurvy in guinea pigs for 60 days. This was further substantiated by other workers using the curative method of experimentation. A 3-month feeding experiment was undertaken in the Bureau of Home Economics of the U. S. Department of Agriculture in which the protective method on guinea pigs was used. A Japan green tea labeled " rich in vitamin C " was used in the form of an infusion of a level teaspoonful to the cup infused 4 minutes. Only sugar was added to the tea infusion which was fed to guinea pigs which had been kept on a basal diet supplemented by cabbage and carrots until weight gains were noted. In addition to the animals receiving tea there were positive controls with orange juice and negative controls with the basal diet alone. The tea and orange juice were given 6 days a week. Tables are given of autopsy findings showing the severity of the bone changes and hemorrhages. Guinea pigs receiving 15 c.c. of tea lived on an average of 42.7 days and those receiving 10 c.c. of tea averaged 39.3 days, while the negative controls averaged 36.5 days. The animals receiving 2 c.c. of orange juice lived throughout the period of 90 days and made gains in weight with no symptoms of scurvy. Guinea pigs receiving tea lived slightly longer than the negative controls. It was concluded that the amount of vitamin C present in this tea is very small. Discrepancies between these findings and those of previous investigators may be due to the use by the former of milk in the tea and also to the probability of the presence of undepleted vitamin C in the animals when the curative method is used.—Hazel E. Munsell and Hilda Black Kifer, *J. Home Econ.*, 21: 514 (July), 1929.

Distribution of Vitamin B_2 in Certain Foods—Previously reported work has established that vitamin B_2 is present both in fresh, unheated yeast and in autoclaved yeast and that cereals are richer in vitamin B_1 than in vitamin B_2 and the reverse is true of milk. This experiment employed wheat and maize kernels since it is alleged that pellagra is more prevalent in the case of maize than in wheat diet. The basal diet consisted essentially of an antineuritic concentrate and casein mixture purified as far as possible to eliminate vitamin B_2 and supplemented by cod liver oil. The cereals were mixed with a basal ration so as to keep the proportion of protein, carbohydrate and fat as 20 : 60 : 15. The cereal modified ration was fed to young rats which had been on a basal diet for 1 week. Comparisons of growth were made in the 4 weeks after the first week on the modified diet. Two different types of whole wheat were tested as well as various portions of the berry. Fifty per cent of whole wheat was required in the diet for sufficient growth. The endosperm is a poor source of vitamin B_2. Wheat embryo and bran are equivalent, 15 to 30 per cent providing sufficient vitamin. Fifty per cent maize in the diet was insufficient for normal growth. The endosperm " grits " are very low in the vitamin but the value of maize as a whole is lower than that of wheat.

Dried ox liver, yeast and fresh whole milk are good sources of vitamin B_2 while dried meat and egg yolk are better than the cereals. There is a discussion of the deficiency symptoms in rats as shown when vitamin B_2 is absent from the ration and this is compared with the black-tongue experiments on dogs and with the "P. P." factor in human beings. All three are assumed to be similar and involve the vitamin B_2 or pellagra-preventive factor.—Wallace Ruddel Aykroyd and Margaret Honora Roscoe, *Biochem. J.*, 23: 483, 1929.

Further Observations on the Effects of Large Doses of Irradiated Ergosterol—Reference is made to the work of previous investigators (abstract this JOURNAL, 19, 10: 1160 (Oct.), 1929) reporting injurious effects of over-doses of irradiated ergosterol and the experiment was undertaken to determine the cause of the formation of the calculi in experimental animals. Rats were placed on an experimental diet consisting of 1 per cent of irradiated ergosterol in cacao butter so that 10 gm. of the completed diet contained 20 mg. of the irradiated ergosterol. Urine was collected from the rats in 3-day periods and analyzed for phosphates, chlorides, and pH value. The rats which maintained a steady food consumption during the control period immediately lost appetite when the irradiated ergosterol was fed. They lost weight for a short period but after this the weight remained constant. The urine output maintained a constant level throughout the experiment but the phosphate excretion varied from day to day and at a high level compared to the control animals. Three days after the administration of the ergosterol diuresis appeared which continued throughout the experiment. The cause of the diuresis is unexplained unless it is due to the marked increase in the calcium excretion. Determination of the chlorides and pH value of the urine during the last days of the experiment showed no differences in these over the controls. After the onset of diuresis the total phosphate remained practically at its previous level with daily fluctuations.—John Clifford Hoyle and Harry Buckland, *Biochem. J.*, 23: 558, 1929.

The Storage of Manganese and Copper in the Animal Body and Its Influence on Hemoglobin Building—In a previous paper (abstract this JOURNAL, 19, 3: 327 (Mar.), 1929) data were presented to show that copper and manganese were effective in hemoglobin formation. This paper presents data to show that manganese and copper may be stored in the animal body. Whole cow's milk supplemented by 0.1 mg. of manganese as chloride was fed to young rats for 5 weeks, after which the manganese was replaced by 0.5 mg. of iron chloride. The second lot for the same period received 0.05 mg. of copper as sulfate, for which 0.5 mg. of pure iron was later substituted. The third lot received 0.5 mg. of pure iron as chloride for the entire period. The first 2 lots showed a low hemoglobin content until the iron supplement was added. The third lot gradually developed anemia but not so rapidly as those without the iron supplement. It is concluded that the animal utilizes a small amount of iron due to copper or manganese stored in the body at birth.—R. W. Titus and J. S. Hughes, *J. Biol. Chem.*, 83: 463 (Aug.), 1929.

Experiments on Nutrition. IX. Comparative Vitamin B Values of Foodstuffs—A number of foodstuffs were examined in this work for the vitamin B (complex), pigeons being the experimental animals. The criterion of vitamin B value was the maintenance of growth for a period of at least 26 weeks. Work has been reported in which the standard for comparison was the hatching and rearing of young which it is

found required a greater amount of vitamin B than for maintenance. The foodstuffs tested were split peas, whole dried green peas, lentils, haricot beans, soya beans, peanuts, almonds ground and whole, hazel nuts, chestnuts, cocoanut, and coffee. Taking as 100 the vitamin B value of 4 per cent of dried yeast to maintain growth for 26 weeks or longer, the various foodstuffs tested ranged by comparison from 20 in the case of peanuts and hazel nuts to 0 in the case of cocoanut and roasted coffee. Green coffee compares favorably with soya beans, lentils, and peas, a comparative value of 13. The remaining products have a value of 10 on this scale. The authors state that at present it is not possible to differentiate the vitamin B complex into its two factors and the results are considered as due to the combination.—R. H. A. Plimmer, W. H. Raymond, and J. Lowndes, *Biochem. J.*, 23: 546, 1929.

Nuts as a Possible Source of Escherichia Coli Found in Candy—Since *E. coli* is used as an indicator of fecal contamination it was deemed worth while to investigate the question of whether nuts might be an indirect source of *E. coli* sometimes found in candy. All the samples were secured in paper boxes or in paper bags as commonly dispensed in the market. Nuts were obtained from a wholesale distributor and from small retail shops.

The presence of *E. coli* was determined by gas and acid production in lactose broth followed by confirmation on Endo medium. The organisms were subsequently identified by further cultural tests. From the wholesale manufacturer of candy 200 samples comprising 10 varieties of nuts were obtained. The colon group, including all aerobic Gram-negative rods producing red colonies on Endo agar and fermenting lactose broth with 10 per cent or more of gas, was found 23 times, or on 11 per cent of the samples. When the members of the colon group were identified, only 4 met the requirements for *E. coli* or *E. communior*, giving a percentage of 2, or essentially the same as was found on previous examinations of candy. Four hundred nuts from retail shops were examined. The colon group was found 86 times, or on 21 per cent of the samples, being twice as prevalent as in the samples from the wholesale store. Only 2 cultures proved to be *E. coli* or *E. communior*, giving a percentage of 0.5. This figure is lower than that found previously from candy and does not support the surmise that the nuts used in certain types of candies are largely responsible for the *E. coli* found. The figures obtained seem to indicate that the *E. coli* found on either candy or nuts comes from the hands of the vendors.—John Weinzirl, *Am. J. Hyg.*, 10: 265 (July), 1929.

Two Outbreaks of Food Poisoning Probably Due to B. Cloacae—During a period of a year and a half, 3 outbreaks of food poisoning, involving a small number of persons in each instance, were reported to the Division of Health of Cleveland. Epidemiologic investigations showed that in each outbreak the food common to all persons was custard puffs from one large bakery concern. The rapid onset of symptoms indicated that the illnesses were intoxications and not infections. Laboratory examination of cream puffs obtained from the houses where illnesses had occurred and of unsold puffs returned to the bakery showed varying results, some being heavily contaminated, some moderately, and others almost sterile. Plate counts of the puffs of the infected lot showed that some contained as many as 68,000,000 bacteria per gm., whereas fresh puffs from 7 other bakeries had counts ranging from 2,000 to 74,000 per gm. No bacteria of the Salmonella group, which are commonly accepted as true food poisoning organisms, were iso-

lated. The flora of the suspected custard puffs consisted of *B. aerogenes* in large numbers, very few *B. coli, sarcina* and many *B. cloacae*. Anaerobic cultures made after heating the stored custard showed no growth. Sterile filtrates of cultures of the organism designated as *B. cloacae,* which was not exactly typical in that it was a slow lactose fermenter and was at first thought to be *B. proteus,* were injected intravenously into rabbits causing marked diarrhea, severe prostration and, in some cases, death. The presence of *B. cloacae* in the food and the demonstration of the ability of this organism to produce thermostabile toxins made it a fairly clear case of poisoning due to this organism. The absence of the usual fecal flora in the puffs together with certain bacteriological findings in and about the cooking room indicated that the ordinary food poisoning group organisms were not involved.

An investigation was made to ascertain why certain batches of custard prepared at this bakery were in good bacteriological condition and caused no illness while other batches contained large numbers of toxic organisms. A chain of circumstances was disclosed involving the practice of placing pans containing the suspected custard on wet floors contaminated with dirt which entered through nearby ventilators, the soiling of the baker's hands from the bottoms of these pans and the use of the unclean hands for scraping the custard from one pan to another. Filtrates of a culture of *B. cloacae* obtained from a ventilator were injected intravenously into rabbits causing symptoms similar to those produced by filtrates from *B. cloacae* cultures from suspected cream puffs. From the epidemiological and experimental data reported showing that an organism of the *cloacae* type was present and members of the paratyphoid group were absent in these outbreaks and that cultures of the organism obtained from the food produced a substance toxic for rabbits, it is concluded that *B. cloacae* was the probable cause of these outbreaks.—Enos B. Buchanan and Emerson Megrail, *J. Infect. Dis.,* 44: 235 (Mar.), 1929.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Milwaukee Next—On June 9, 1930, the biennial convention of the 3 national nursing organizations in this country will open its sessions at the auditorium in Milwaukee, Wis. These 3 organizations are the American Nurses' Association, the National League of Nursing Education and the National Organization for Public Health Nursing.

The Mental Hygiene Section of the biennial promises to be one of the most interesting. Section officers are tabulating answers to questionnaires sent out to state presidents and to state boards of nurse examiners as to the situation in regard to the education of nurses in mental hygiene and psychiatric work.

The mental hygiene program will be especially interesting also, because it follows so closely the First International Congress on Mental Hygiene which will be held in Washington, D. C., May 5–10, 1930. Here will be discussed the relation of mental hygiene to law, hospitals, education, industry, social work,

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

delinquency, parenthood and community problems.—*Bull.*, American Nurses' Association, Oct., 1929.

Vacations and Sick Leaves for Public Health Nurses—In answer to a questionnaire sent out by the statistician of the National Organization for Public Health Nursing to 73 health departments, 72 per cent stated that the yearly vacation given to their nurses was two weeks. Of the 99 public health nursing associations questioned, all but 7 per cent stated that one month was the vacation time given their nurses.

The most frequent length of time allowed nurses in a year for sick leave with full pay by health departments, school boards and public health nursing associations was found to be 2 weeks.

Out of 128 boards of education employing nurses, 63 per cent of these in cities of 100,000 or more population require their nurses to work on Saturdays. Only 20 per cent of the boards in cities under 100,000 require their nurses to work on Saturdays.—Louise Tattershall, Pertinent Facts Relative to Salaries of Public Health Nurses, *Pub. Health Nurse*, V, XXXI: 444–445 (Aug.), 502–503 (Sept.), 1929.

(NOTE: Further reports of the results of Miss Tattershall's studies along this line will be published in other issues of *The Public Health Nurse.*)

Hygeia Helps the Public Health Nurses—In the November, 1928, issue of *Hygeia*[1] there was a health-score outline for teachers which was worked out by the Committee on Hygiene and Physical Education of the Massachusetts Federation of Teachers' Clubs. This score was divided into two sections: I. *Signs of Health*, under which there were 17 items, and II. *Health Habits*, with 24 items.

Several public health nurses in Indiana used this score to good advantage at the beginning and end of their hygiene classes in high school, to measure the improvement in health habits and health of their students during the school year.

One school nurse who was asked to talk before the Lion's Club at a noon luncheon made mimeographed copies of the score and distributed them to the men, who scored themselves at the meeting and were very enthusiastic about it.

Another public health nurse distributed the score sheets at a Parent-Teacher Meeting and created a very deep interest in everyone present. There was great surprise that a visit to the dentist twice a year counted 40 and a thorough physical examination once a year counted 50 towards the whole possible score of 530.

In the October, 1929,[2] issue of *Hygeia* there is a score outline for the home in regard to sanitation, communicable disease control, child hygiene and health education. And this, too, ought to be widely used by the public health nurses in interpreting the health needs of the household in a practical and interesting way to either individuals or groups.

County Nurses and the Conveyance of Patients—Nannie J. Minor, R.N., Director of Public Health Nursing for the Bureau of Child Health, Virginia State Board of Health, has been making a study in her state as to how much time and money the county public health nurses are spending in the conveyance of patients to sanatoriums and hospitals. She states in her questionnaire sent out to the nurses, "We are seeking for information, with a desire to clarify as far as possible the multiplicity of duties which are constantly being heaped upon the health worker and which could be done just as well by other people." Forty-six nurses replied. The questions which applied only to the past 6 months are given below with their answers:

1. How many times have you personally conveyed a patient to a sanatorium in your car?

37 replied no patients
1 " 1 "
3 " 2 "
1 " 5 "
1 " many times

2. How many times have you personally conveyed a patient to a hospital?

14 replied no patients
11 " 1 "
2 " 2 "
2 " 3 "
4 " 4 "
1 " 5 "
1 " 9 "
1 " 10 "
1 " 11 "
1 " 12 "
1 " 50 "
1 " 130 " or an average of 5 or 6 a week
1 " 288 " to clinics
1 " many times
1 " 2 patients—taken on train
1 " 1 patient—taken on train
2 " not clear, as only in an emergency

3. If it means some distance, why is the car preferred over the train?

20 did not reply
7 said patients taken if the distances were short
1 reported poor train service
3 reported when patient was very ill there were no funds
3 stated distances longer by train
6 stated no train service was available
2 stated less time and less expense
3 stated several patients could go at once at less expense and greater comfort
1 stated train was always used

4. What has been the approximate expense of such trips and about how much time was consumed by the worker?

28 did not reply
The remaining 18 varied from 75¢ to $10.00
23 did not reply as to the amount of time spent
The remaining 23 gave time from ½ hour to 32 hours

5. Why was it necessary for the health worker to accompany the patient?

22 did not reply
The answers of the remaining 24 are rather interesting
1 stated "part of my work"
4 stated "friends and relatives do not understand how to manage nor how to get reduced rates at the hospital"
1 replied "information health worker can supply"
2 replied doctor requests nurse to go
7 replied no other person available
9 replied patients dangerously ill—no funds available

6. Do you think that such activities have any place in your work?

28 stated that frequently it helped popularize the work
15 replied "no"
3 failed to reply

The study does not show how many of these visits were repeated for the same patients. Many nurses make it a rule to take the patient to the hospital or sanatorium or clinic, as the case may be, for the first time in order to answer questions about his history and social conditions, and this often aids greatly in the solution of his problems and in his improvement or final recovery. She in turn can convey the information and the advice given at the hospital or sanatorium or clinic to the patient's physician and family at home. In emergency cases she is often the only one available for quick action—here mobilization of volunteers might cause dangerous delay. But to accompany chronic patients week after week to hospitals for treatment, surely wastes a nurse's valuable time and she ought to make some arrangement for volunteers to do it.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

The Harmon Awards Next—The most important opportunity this season for recognition of good health education publicity is offered through the Harmon Foundation awards for a Year's Publicity Record—$100 each is offered for the best record submitted by a national agency, a state or regional agency, a city or county agency of 200,000 or more population, and a city or county agency—under 200,000 population.

The conditions are simple. The making of such a record should be extremely valuable to any alert health agency—well worth while even though the prize is not won. We hope that all health agency entries can be exhibited at the 1930 meeting of the A. P. H. A. The Harmon Foundation, 140 Nassau Street, New York, N. Y., will gladly send the conditions. Will you ask for copies to be mailed to all health organizations in your city, county or state? Nationals are invited to distribute copies and to urge their local groups to enter the contest.

Local and State Health Education Councils—Why not get together locally and in connection with state health and social work conferences? Four or five local luncheon or dinner sessions this season, and a session or two at the next state meeting, should do much in boosting interest and effectiveness in public health education. Merely to talk over whatever anyone in the group has on his mind would be worth while. Submit copies of your material for informal comment. Invite the presence of a printer or a newspaper man and ask him questions about your material. Set up any one of scores of questions or problems and see what the group has to contribute. Appoint a chairman and a secretary to plan and call the next meeting.

What group will announce that they are getting together?

The Yard Stick—

To ascertain the "subject matter" for publicity work in a health department I have drawn up a guide based on the appraisal form of the American Public Health Association. After keeping in close touch with department heads for more than a year to make the publicity keep in step with their activities and perhaps get out in front once in a while and stir things up for them, I found that department activities aimed to make up shortcomings pointed out in local health work when the appraisal form yardstick was applied to our program. Consequently, to find the "subject matter" for publicity it was only necessary to set aside activities in which points were lost in getting our rating. For instance—we lost 11 points because not enough pre-school children visited clinics. Therefore, more publicity for pre-school clinics. We lost 4 points because of lack of nutrition work. Therefore, more publicity for nutrition work. Good copy is available because the publicity man knows the health department's program is in step with his own.

—George A. Dundon, Director of Health Education, Health Department, Milwaukee, Wis.

EXHIBITS

Practical suggestions for taking part in the fair are continued in these articles: "Babies Rest at the Fair," "First Aid Tent," "Some Suggestions for Health Exhibits," "During a Community Chest Drive," "What Not to Do in County Fair Exhibits." *Pub. Health Nurse.* Aug., 1929.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

"The Diphtheria Prevention Commission has prepared twelve attractive panels as a technical exhibit on the prevention of diphtheria. This set is intended primarily for health officers in showing the way to a coördinated community campaign to wipe out diphtheria. Each panel is 32 by 43 inches. The backgrounds are appropriate designs on which are superimposed the forms used by the Commission in its work in New York." Application for the loan of the exhibit may be made through Edward Fisher Brown, Director, Diphtheria Prevention Commission, 505 Pearl Street, New York, N. Y.

A health exhibit won a first prize of $100.00 at the Tompkins County, N. Y., Fair, and will be shown at the county fairs in the state. Planned by Nina V. Short of the staff of Tuberculosis and Health Committee, S. C. A. A., the exhibit was designed to present the county health department services. The exhibit shows in miniature the court house and clinics, with an attractively painted background.

The historical exhibit at the recent National Tuberculosis Association exhibit, Atlantic City, N. J., suggests possibilities for other groups. The "antique" publicity section might be worked out in connection with the 1930 meeting of the A. P. H. A. It would help to show progress made in educational materials.

"How Pasteurization Safeguards Your Milk Supply"—*N. E. Journal of Medicine.* Jan. 24, 1929. *Monthly Bulletin,* Board of Health, Fall River, Mass. July, 1929. Issued as a leaflet by Mass. Dept. of Public Health. *Free.* Effective thermometer diagram—good for exhibits and printed matter—with text answering "What Is Pasteurized Milk?"

Models of two houses in neighboring lots represented "the house of good health" and "the house of ill health." The house of good health was shown on a plot with a green lawn, split peas being used for grass. The foundations of the house were made of zwieback, the material of the walls and chimney were layer-figs, the roof, graham crackers, awnings were of orange peel, the doorstep and the walk of triscuit. Trees were of celery in a tomato setting, the stiff shrubbery was represented by carrots and the children on the grounds were made of dates. The house of ill health appeared set in a grass plot of coffee giving the appearance of a drought. The garden walls were of lump sugar, and the house itself was of coffee stucco. A granulated sugar walk and cake steps led to it. The children were made of various kinds of highly colored candies.

—*Health News,* N. Y. State Dept. of Health. July 8, 1929. This exhibit was recently prepared for the Health Dept., Glens Falls, N. Y. A well-done revival of an idea in use for several years. Its educational value depends upon the talk by a good explainer who will make obvious the difference in the food values in the materials used in the two houses. Standing alone, will the exhibit be much more than a curiosity?

Pictures of a "Health House" exhibit at the Rochester Exposition appear in *Bulletin,* Tuberculosis and Health Association, 35 Chestnut St., Rochester, N. Y., July, 1929. *Free.* The barker invites visitors in with

Come on, folks, right this way to Healthy House. Everything free. Won't cost you a cent. Everybody Healthy—that's what we want—step right in. See the poor little white rat that never drank any milk. See the three bears who sleep in their own separate beds, eat hot cereal and walk every day in the open air just as Goldilocks discovered them. Get a ticket for the anti-toxin express train for No Diphtheria Town. Have the baby weighed—yes, we have pretty nurses who weigh all the babies under six. . . .

"Popularizing Prenatal Education," by Helen Albano. *Trained Nurse and Hospital Review.* June 29, 1929. Pp. 789–791. Describes in detail a department store demonstration of home confinement. Diagrams and pictures show the arrangement of objects in the demonstration space.

HEALTH SUPERSTITIONS

"Folk Doctoring." *Public Health*, Central Board of Health, Kingston, Jamaica. Aug., 1929. "Did he ever kick the cat? That's one of the causes for joint rheumatism."

"Toothache's Place in History." *Sunday World Magazine*, New York. Sept. 1, 1929. *10 cents.* Charms, whiskey, apples and other "cures."

Ancient and modern health superstitions should make good copy for the Sunday newspaper. And there are plenty of them now current.

NEWSPAPERS

In the 1929 "Feature Story Contest" of the Social Work Publicity Council a first prize was awarded Dwight Anderson, National Tuberculosis Association, for his story, "Roentgen Ray Lights Way in War on Plague." Said the committee: "This story is historically and scientifically informative and yet retains the breeziness and crispness of expression so essential to successful newspaper work."

The award of a medal to Dr. Ernest Fuchs, of Vienna, was used as the lead of a press release to announce the reelection of a president of the National Society for the Prevention of Blindness —the latter event in itself not of widespread newspaper interest. Released July 29, 1929. *Free.*

"Questionnaires as a News Source" quotes the publicity department of the National Board, Y. W. C. A., on questionnaires as supplying material for news copy which can be given an educational slant. See *News Bulletin*, Social Work Publicity Council, 130 East 22d St., New York, N. Y., Sept., 1929.

Questions about health habits, health beliefs, what people know about health departments or other health agencies, reading on health topics, and so on, can be handled by mail, at meetings, with individuals, and among special groups. As a rule statements of results will be welcomed by editors and appeal to many newspaper readers who would not be attracted by paragraphs discussing the unadorned subject matter.

Attendance figures at Massachusetts state cancer clinics, as discussed by *New Bedford Standard*, show that

> in the state as a whole 45.2 per cent of those who reported to a clinic were led to do so by what they had read in the papers. . . . In New Bedford the percentages for newspapers, doctors and friends were 56.8, 21.1 and 12.1, respectively. . . . In New Bedford 22.5 per cent of those attending were found to be suffering with cancer. . . . If they are cured, the clinic has accomplished a wonderful thing, and in bringing this about intelligent newspaper publicity has been an important factor.

"Annual Directory of Features," in *Editor and Publisher*, Times Bldg., New York, N. Y., Aug. 31. *10 cents.* Lists features supplied by syndicates to newspapers, feature and picture syndicates, news services, photographic services, mat and cut services, syndicate writers and artists.

"Health columns" supplied by newspaper syndicates are written by the following: Dr. M. Schuman, Dr. Lulu Hunt Peters, Dr. Frank McCoy, Dr. Logan Clendening, Dr. W. A. Evans, Dr. Morris Fishbein, Josephine Huddleston, Bernarr Macfadden, Dr. Herman Bundesen, Dr. McCoy, P. J. Veatch, Dr. Royal S. Copeland, Leon F. Whitney.

TO CATCH THE EYE

Distinction can be given to mail by the use of large postage stamps. The following two-cent stamps can be bought through Philatelic Agency, City Post Office, Washington, D. C.:

Valley Forge (1928)
Aeronautic Conference (1928)
Burgoyne Campaign—Saratoga (1927)

The Burgoyne stamp is small, but unusual. Two-cent Sesquicentennial envelopes in 3 sizes are quite different from the usual ones. *Send for order blank.* But try your local post office first.

An example from the colored picture map on cover of "Radburn Garden Homes" may suggest use of a similar graphic device to indicate the location of a health activity, the community served, etc. This particular pamphlet describes "a new safety street plan" and other ideas on new housing developments. City Housing Corporation, 18 East 48th St., New York, N. Y. *Free.*

"Just What Is a Poster Anyway?"—A poster is to the eye what a rallying cry is to the ear. It is to sight what a crusader's slogan is to sound. A poster has something to say, and says it hard. It has no patience with negative virtues. Its aim is to get things done. It runs on a single-track line of thought. Through the eye of the beholder, its singleness of purpose and its sincerity must be instantly and wholly comprehended.

—From "How to Make a Poster," in *"Seeing Is Believing."* American Child Health Association, 370 Seventh Ave., New York, N. Y.

WHAT WE FOUND IN SOME HEALTH BULLETINS

"A Dental Health Exhibit as a Project in Health Education" is described by Pearl E. Wilson, R.N., director dental health education, State Department of Public Health, Oklahoma, in *The Public Health Nurse* for September, 1929.

"Health Education in Teachers' Training Schools" is a report on a five-year study at the New York Training School for Teachers by Iago Galdston, M.D., secretary, health education service, New York Tuberculosis and Health Association, New York, N. Y. It contains an outline of the curriculum of health education course given at New York Training School for Teachers. Copies may be ordered at 50 cents each from New York Tuberculosis and Health Association, 244 Madison Avenue, New York, N. Y.

Wanted, an Author—"Who will be the Emily Post of Public Health?". The U. S. Public Health Service has coined the term "Sanitary Etiquette" and suggests that somebody write a book about it, called "The Hygiene of Etiquette," to teach prophylactic measures and practical hygiene as well as social courtesy. Some of the unhygienic indiscretions to be barred by the contemplated volume are coughing and sneezing without protecting the mouth, indiscriminate kissing, insistence upon hand shaking, blowing the nose on a soiled handkerchief, later used for other purposes; moistening various articles, such as money, books, tickets, etc., with saliva are also deprecated.

—*Clip Sheet,* N. J. Tuberculosis League, Inc., 21 Walnut St., Newark, N. J.

We think this is good—A radio talk that is easy to listen to is quoted below: "When you or some one in your family wakes up in the night with a terrific pain in the stomach, a high fever, a sudden chill or something else and you want a physician badly, it is comforting to realize that you have a family doctor. You ring him up on the 'phone, perhaps you call him by his first name, and very shortly he is at your side. With his entrance into your home there is immediately a sense of relief because you know and have confidence in your doctor. Besides this he knows from previous visits in the home the health and sickness background of each member. The doctor quickly sizes up the present situation and takes command and you follow confidently his advice and instructions.

"Picture, if you will, this same urgent need in a family that has no regular doctor. The first question to decide is who to call. Should it be a stomach specialist, a throat specialist, a surgeon or a general medical man? When this is decided upon the telephone is put to use. The responses may be varied but often unsatisfactory. 'I go out at night only for my regular families.' 'I limit my work to nose and throat work,' or, 'I am just going out on another case; try Dr. Blank.' Finally you are successful in getting someone to respond to your appeal and he arrives, a stranger in the home. You look him over and are not quite sure just how much confidence you

should place in him and he is sizing up the situation to see whether he is likely to get paid for being pulled out of bed. The physician has to ask a lot of questions to get the history of the case and then he proceeds to his examination, an unknown doctor for an unknown patient. He may recommend immediate hospitalization, an operation, or come to the conclusion that a cathartic is all that is necessary. You probably follow his advice no matter what it is but you cannot help but feel a little uneasy about the matter.

"Every family that can afford it should have a regular physician. This physician should see the family every year whether there is sickness or not. He should be asked to do physical examinations on everyone annually and give proper advice for the prevention of disease and the care of defects. Occasionally one hears the remark, 'We haven't had a doctor in our house for five years and wouldn't know who to call if there was sickness.'

"As a rule families have their own grocer, banker, and spiritual adviser, etc., but too frequently the family physician is neither chosen nor made use of until late in the contest between health and sickness."—Have You a Family Doctor? in *Health*, published by the New Haven Department of Health. July, 1929.

Sometimes we enclose a printed card with reports and other special publications when sent to certain lists. As an inexpensive substitute for the printed card Bellevue-Yorkville Health Demonstration has used a stock 3 x 5 card on which was multigraphed "With Compliments" followed by the name and address in the center, and the name and title of the executive at the lower right corner—the Demonstration title and executive's name all in caps.

"The Attention-Getting Phrase in Your News Lead" (*News Bulletin*, Social Work Publicity Council, June, 1929) quotes from Dwight Anderson a list of phrases for the opening sentence, the "lead," of newspaper stories, accompanied by the news element out of which each phrase grows. Examples: "Aroused by—," "Seeking to avert—," "To ascertain why—," "Final action on—." A valuable list for desk use.

"Which Way Publicity?"—This question is raised in a lively fashion—and answered with a bang by Leigh M. Hodges. *Survey*, 112 East 19th St., New York, N. Y. July 15, 1929. *25 cents.* Although addressed to child welfare agencies its sharp thrusts will pierce the armor of all but the hopelessly self-satisfied, and unwilling-to-learn health workers.

REQUEST FROM LONDON

The following comes from T. Crew, organizing secretary, Central Council for Health Education, 1 Upper Montague Street, Russell Square, London, W. C. 1, England:

> The Central Council is coördinating the various health associations in this country and also preparing a Museum of Health Propaganda in order to be of service to the medical officers of health and others engaged in public health services, etc.
>
> The Council would be glad if you can kindly supply them with any health posters and health leaflets, etc., for display in our Museum.

IN THE MAGAZINES

"Eat, Drink, but be Wary," by R. S. Copeland, M.D. *Collier's*, July 13, 1929. Germs and refrigeration.

"Get a Mouthful of This," by Ruth F. Wadsworth, M.D. *Collier's*, Sept. 28, 1929. Tooth decay: Why? Why not?

"Mechanized Medicine." Editorial. *Sat. Eve. Post*, Sept. 7, 1929.

"Vitamins in Margarines," by E. E. Slosson. *Collier's*, Aug. 24, 1929.

BOOKS AND REPORTS

A History of the Medical Department of the United States Army—*By P. M. Ashburn, Colonel, Medical Corps, U. S. A. Boston: Houghton Mifflin,* 1929. 448 pp. Price, $5.00.

Every present and former member of the Medical Department of the U. S. Army ought to read this book, which is the first comprehensive and satisfactory history of this extremely important branch of our military forces. Officers of the active services and of the organized reserves ought to receive credit for doing so, not because the book is hard reading, for, though lengthy, it is the reverse. The struggles and vicissitudes, the achievements and triumphs of our medical soldiers, as described and occasionally commented upon by Colonel Ashburn, who is exceptionally well qualified for this task, are always interesting and frequently entertaining and instructive.

The story begins with the hectic days of 1775 and spans the whole career of the service up to 1928. The first part, dealing with the period before the Spanish-American War, is, of course, compiled entirely from available records and so lacks some of the verve of the later sections, such as those on the World War, when the author could draw for his facts on personal experiences as well as authentic records. While the book gains momentum as it progresses, this is no disparagement of the earlier parts.

The account is an impartial one, with no attempt to gloss over some of the less creditable incidents in the history of the Medical Department, such as the lack of preparation and of efficiency in the early years of the Civil War and more or less throughout the Spanish-American conflict. At times some of the quotations from old documents seem a little prolix, and the informed reader will not always agree with the author's evaluation of personalities and events. Members of the Sanitary Corps will also be disappointed at finding so little about this branch of the department which rendered such valuable service during the World War.

Despite these minor defects, if they are shortcomings, this well-printed book is a notable contribution to medico-military literature. It fulfills a real need and deserves a wide circulation. There is an introduction by Surgeon General M. W. Ireland and a number of useful appendices, including a well-merited appreciation of Surgeon General Ireland, contributed by General Pershing.

JAMES A. TOBEY

The Child's Heredity—*By Paul Popenoe. Baltimore: Williams & Wilkins,* 1929. 316 pp. Price, $2.00.

The author has the happy faculty of making this rather heavy subject interesting and at times even entertaining, not only by choosing good material and language but also, when perhaps his reader may be a bit weary, by telling him that: "Some youths have asserted that all blondes are fickle and all brunettes inconsistent. It is not a given type of complexion, however, but sudden change from one type to the other, that is properly to be considered as an evidence of instability." Other illustrations *are* apropos and not simply amusing.

The author, we think, must possess an ancestry of several millions—or less—of generations of Presbyterians, so strong does his belief in predestination and the inevitability of results from given forebears appear; yet we imagine that had he been employed as counsel

by the proponents of environment as the dominant factor in child development, he could and would have found enough variables to leave his readers, who have but mediocre prospects from heredity, some hope through training.

Parents will find this book a good one to add to their general cultural knowledge and we trust that many will read it, but the preface says: "This is a guide book for parents. Their interests and practical needs have determined the selection, the arrangement and the treatment of the material," and yet about all the "guidance" we find is contained in nearly the last line where the author says: "The greatest opportunity a man ever has to exercise this choice [of conditions favoring race evolution] is in the selection of a set of genes to add to his own for the creation of children."

The book contains good reliable material well arranged and is an excellent presentation of the subject from the angle of major emphasis on hereditary influence. W. D. LUDLUM

Health Science and Health Education for College Students and Teachers in Training—*By W. Alfred Buice. New York: Wiley,* 1929. 344 pp. Price, $3.00.

This is an effort to combine personal and community hygiene. The book is divided into four parts—part I dealing with preventable diseases and how they may be prevented; part II with personal hygiene and efficiency, including a chapter on reproduction and sex hygiene; part III relating to such community health factors as milk safety, child conservation, public health administration, and the public school health program; part IV is made up of projects and exercises for class use, and of first aid exercises. There is also an appendix on nutrition, offering standard dietaries for persons of different weights and activities, and fattening diets for those needing them.

Part IV offers a wealth of project material and suggestions which teachers in training may use later in their own teaching.

The text is designed for the use of college students and teachers in training. The material is well organized, sufficiently illustrated, and clearly stated. Supplemented by the projects and exercises of Part IV, this work makes an excellent text for the designated group. A worth while book in a field, particularly as regards teachers in training, that needs emphasis. C. H. KEENE

The New Healthy Living—*By Charles-Edward Amory Winslow, Dr.P.H., and Mary L. Hahn. New York: Merrill,* 1929. Book I. Price, $.84. Book II, 438 pp. Price, $1.00.

In Training for Health—*By C. E. Turner, Dr.P.H., and Jeanie M. Pinckney. Boston: Heath,* 1929. 151 pp. Price, $.72.

Science and the Way to Health—*By J. Mace Andress, Ph.D., and Maud A. Brown, M.S. Boston: Ginn & Co.,* 1929. 367 pp. Price, $1.00.

Sanitarians will want to know about this summer crop of school health readers. They will be interested, not so much in the relative merits of each, but in the fact that those most competent to guide the school child's hygienic life are putting themselves to the task of preparing good books.

Of the 4, 2 are for youngsters of about the fourth grade, and the others for boys and girls in the junior high grades. All are written for children who are presumed to have had some health instruction.

Obvious analogies between training for athletic success and training for life, inspirational stories about well-known persons who have achieved the healthy life despite a poor start, interesting tales of "microbe hunters," and curiosity-stimulating accounts of our internal processes all go to make the books good,

as well as helpful reading for the youngsters.

To a reviewer old enough to have suffered under the old régime of so-called health teaching, yet not so old as to have forgotten the deadly dull physiologies of his own school days, the perusal of this series of health readers is indeed a pleasant assignment. Vivid still are the memories of the 208 dry bones whose fiendish names had to be learned by rote. I can still see myself standing limply in the aisle reciting with utter boredom, ". . . and the bones of the arm are the femur and the ulna . . ." and so on *ad nauseam.* The memory of the names and uses of the countless muscles happily is clouded by the merciful mists of forgetfulness.

R. S. PATTERSON

Readings in Public Opinion. Its Formation and Control—*Edited by W. Brooke Graves, Ph.D. New York: Appleton,* 1928. 1281 pp. Ill. Price, $6.00.

The editor, professor of political science in Temple University, has accomplished a colossal piece of work; i.e., compiled a volume of nearly 200 essays and discussions on the various subjects that are related to the formation and control of public opinion.

In his introduction to the volume, Clyde L. King, Ph.D., professor of political science, University of Pennsylvania, takes up the importance of public opinion and its distinguishing elements.

The first section of the book is more or less analytic, for the editor has grouped contributions dealing with the formation of public opinion, the rôle of discussion in its formation, the nature of group opinion as contrasted with general public opinion, the scope of public opinion, how it is influenced by environmental and hereditary conditions and its power in the community.

According to the editor's analysis, as brought out in his plan of presentation, there are certain established social institutions which influence public opinion. They are all familiar to the reader—the school, church, press, theatre and motion pictures, art, literature, music, the radio, and oratory—and here he especially deals with the Chautauqua.

The private organizations that influence public opinion are the public relations counsel, chambers of commerce, corporations and organized labor, trade associations and civic and improvement associations. One chapter is devoted to racial influences.

Then there is the governmental influence—the appeal of the reformer, the demagogue, the leader and the political party and legislation leadership. Included in this volume are articles dealing with lobbying, freedom of speech, censorship, the administration of justice, international public opinion and public opinion in war time.

This volume is a valuable aid to the publicist or the student of human behavior. Although it was probably not compiled with the idea of offering a textbook on the subject, the author has placed at the end of each section topics for further investigation and discussion.

Two indexes—author and subject—are also commendable features of the book. It is sparsely illustrated with cartoons.

This is an excellent volume to have handy on the bookshelf for reference and ideas. ANNE TOWSE

Outline of Preventive Medicine. *For Medical Practitioners and Students. Prepared under the Auspices of The Committee on Public Health Relations, New York Academy of Medicine. 21 Contributors. Editorial Committee: Frederic E. Sondern, Chas. Gordon Heyd, and E. H. L. Corwin. New York: Hoeber,* 1929. 398 pp. Price, $5.00.

This book can at least claim to have been written on a different plan from

other works on preventive medicine. Whether or not it is a good one is open to considerable question. Instead of beginning, as most books on the subject do, with some description of the formation and functions of the body, it goes at once into "The Periodic Health Examination," and then one by one, different specialties, such as obstetrics, pediatrics, dermatology, etc., are discussed by specialists in each particular line.

Written as it is by 21 different authors, it has some of the faults inherent in such productions. In the section on General Medicine, for example, we find no mention of the Dicks' work on scarlet fever, of the recent discoveries in regard to yellow fever, nor of the work of Birkhaug on the particular streptococcus which causes erysipelas, though the leucocytic extract of Hiss is mentioned. The other sections of the book do not entirely make up for these omissions, though the Dick Test as well as the use of streptococcus toxin for immunization is mentioned in the section on pediatrics.

The chapters are each well written, and contain a fund of useful information, though practically all of them presuppose some knowledge on the part of the reader. We believe that the omission of fundamentals detracts from the general value of the book, which is otherwise of high quality.

The printing and make-up of the book are excellent. M. P. RAVENEL

Chemistry of Daily Life—*By Samuel Glasstone. New York: Dutton,* 1928. 250 pp. 21 diagrams. Price, $2.25.

This book is the result of a course of extension lectures given at Plymouth under the auspices of the Education Authority and of the University College of the South-West, Exeter, and of a series of radio talks by the author on the same subject. It is intended for the general reader, and to serve as a basis for extension and similar lectures as well as a textbook for schools whether chemistry is taught or not.

Twenty-two chapters and an index cover 250 well-printed pages, dealing with such subjects as the history of chemistry, structure of matter, air, water, carbon, burning and breathing, flame and explosion, foods, catalysis and enzymes, plants and soils, fuels, metals and alloys, the laboratory in reference to synthesis of dyes, medicines and perfumes, and artificial foods and clothing.

A very valuable feature of the book is the list of questions, suggestions and references to literature that follows each chapter. By the use of this list even the general reader can be led into a definite and systematic study of chemistry.

The beginning student would profit by a more definite consideration of the chemical equation together with the inclusion of a few pages with reference to chemical calculations. An equation, whether chemical or otherwise, is something of a mystery to the initiate; so a little assistance in this regard would go a long way. But this item aside, the book under consideration is one of the best of its kind. C. F. ADAMS

Home Care of the Sick—*By Norma Selbert, R.N. Philadelphia: Saunders,* 1929. Price, $1.00.

Based on a wide experience as a nurse, an extension lecturer and a teacher of public health, the author has given us an excellent book of practical instruction in non-technical language suitable for use in every home. The author's duties have taken her into homes of all kinds, from those of the rich city dweller to those living in remote agricultural districts. She is therefore exceptionally well fitted to judge of what is needed and has given this in a concise and readily available form. She has covered the ground in an excellent fashion.

M. P. RAVENEL

Sunrays and Health—*By Ronald Millar in collaboration with Dr. E. E. Free. New York: McBride,* 1929. 125 pp. Price, $1.50.

The rays of the sun are at last enjoying the popularity of a best seller. They have become the fashion. Clothing designers having put the seal of approval upon them they have a recognized standing. Old-fashioned people who have always appreciated the sunshine may now feel themselves for once quite in style. Furthermore they may find out the scientific basis for belief in the powers of sunshine by reading the well-written little book called *Sunrays and Health* by Ronald Millar and Dr. E. E. Free.

Part of this book is devoted to a simple explanation of the composition and properties of sunlight and the part that the ultra violet element plays, especially in relation to the human body. The geographical distribution of ultra violet is taken up. We find that a place in the sun in New York City is not of much value from November to April so far as getting one's share of ultra violet is concerned. A useful list of window glass substitutes is quoted with figures indicating the percentage of solar ultra violet these substitutes may be expected to transmit.

The ultra violet lamp, however, seems to be the climax toward which the book works. Evidently the authors consider this a wonder-worker. A note of half-concealed criticism is seen, levelled at the conservative attitude of the American Medical Association for frowning on the advertising of generators of ultra violet energy to the general public. Nevertheless the quotation from an article by the brother of the inventor of the mercury arc lamp, although apparently intended to reassure prospective users of "artificial sunlight," seems on careful reading to be far from reassuring.

For the intelligent reader accustomed to taking all his reading with a grain of salt this little book will prove both informative and entertaining.

MERRILL E. CHAMPION

Laboratory Manual of the Division of Bacteriology, Peking Union Medical College—*Prepared under the direction of D. E. Lim. Peking, China: P. U. M. C. Press,* 1929. Price, $1.50.

From China comes this excellent laboratory guide, printed in English by the College Press. The directions are clearly given, and the book in general is admirably adapted to the purpose for which it is intended.

At the end of each section, the references are given, so that the reader may consult the more complete text.

Two omissions are noted. There is no mention of Ponder's stain for diphtheria bacilli, which, in our experience, is by far the best, especially for direct smears, nor of Dorner's spore stain.

The book is well printed and made up.

M. P. RAVENEL

Selected Readings in Pathology. From Hippocrates to Virchow—*By Esmond R. Long. Baltimore: Charles C. Thomas,* 1929. Price, $4.00.

The author has selected from the literature of the past what he considers some of the most important contributions to the science of pathology. What the original writers said of their work is given in their own words, or as near to them as a good translation can come.

What has been given is beyond criticism, and we believe that the selections have been made with excellent judgment. The author deserves the thanks of students and teachers alike for making this material readily available.

The make-up of the book deserves special mention. It comes from the new publishing house of Charles C. Thomas. It is a beautiful book which

will be an ornament to any library, and its material is of rare interest. The illustrations are numerous and good. A page in the rear gives the story of its making. M. P. RAVENEL

Heredity and Parenthood—*By Samuel C. Schmucker. New York: Macmillan,* 1929. 322 pp. Price, $2.50.

The major portion of this book is devoted to the presentation of the biology of reproduction, from the simplest forms up to and including the mammals. This is expressed simply and demands no previous knowledge of the subject and is appropriate to those interested people who have lacked the opportunity of a high school education or more. The reviewer suspects that the subject has not been adequately covered in all high school or college programs even in the present day.

A few of the later chapters are devoted to the relations of the sexes in childhood, youth and early adult life, and the subject and form of sex education; the author's children, then eleven and nine years old, having received a large slice of instruction in connection with the puppies, born by prearrangement, in the house.

The author is deeply religious, with a God who produces creation by evolution. He believes in ample sex education through biology; in early marriage at the proper physiologic age to avoid the errors of delay. He approves of birth control, and of the wife contributing to the family budget, as may be necessary, for a while after marriage.

Altogether we might call him a "Victorian modernist," with the good traditions of that age, modified by modern science and economic necessity.

The title of the book is a misnomer; heredity—inheritance of characteristics, physical or mental—is barely referred to, and parenthood only in the manner mentioned above.

However, this title may achieve the desired effect of attracting the readers he wants. WALTER D. LUDLUM

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Possibilities in Life Conservation—Causes of death grouped by age and sex are shown graphically and the presentation is used as a basis for a discussion of possible preventive measures.

ANON. Where Can Lives Be Saved? Weekly Bull. (New York City Dept. of Health), 18, 34: 265 (Aug.), 1929.

Postvaccinal Encephalitis—Briefly summarizing the prevailing opinion in regard to the possible causes of postvaccinal encephalitis. The preventive measures suggested are avoidance of vaccination in areas where polio and encephalitis are present, use of "American" method of vaccination, and vaccinating during the first year of life.

ARMSTRONG, C. Postvaccinal Encephalitis, Pub. Health Rep., 44, 34: 2041 (Aug. 23), 1929.

Measles Prophylaxis—Another report of the benefits derived from the use of convalescent blood as a preventive of measles.

BADER, G. B. The Intramuscular Injection of Adult Whole Blood as Prophylactic Against Measles. J. A. M. A., 93, 9: 668 (Aug. 31), 1929.

When is an Epidemic?—This delightful dissertation on the relative merits of knowing what to do and how to make the public believe you are doing the right thing discusses methods of obtaining accurate records during epidemics.

BIGELOW, G. H., and LOMBARD, H. L. Respiratory Tract Infections in Massachusetts in the Winter of 1928–29. New England J. Med., 201, 10: 474 (Sept. 5), 1929.

Cancer in Public Health—This discussion of the possibilities of official participation in cancer control recounts again the pioneering work of Massachusetts in this field.

EWING, J. Cancer as a Public Health Problem. Pub. Health Rep., 44, 35: 2093 (Aug. 30), 1929.

Nursing Economics—Although somewhat outside the strict limits of sanitation, this excellent resumé of the present status of nursing is well worth study by all sanitarians.

FOX, E. G. The Economics of Nursing. Am. J. Nurs., 39, 9: 1037 (Sept.), 1929.

Food Poisoning—An outbreak of food poisoning due to eating veal infected with *B. suipestifer* is unusual enough to warrant reporting. This one occurred in Great Britain.

GRIFFIN, A. J. B. An Outbreak of Food Poisoning Due to Salmonella Infection. Med. Off., 42, 11: 119 (Sept. 14), 1929.

Mental Hygiene—A symposium on Mental Hygiene from the point of view of the child and the adult, by a group of distinguished British physicians. The chairman raises this question in regard to the term "preventive medicine." Medicine implies healing; healing implies deviation from health. The object of preventive medicine is not to rectify deviations from health, but to prevent the necessity of "medicine."

HALL, A. J., *et al.* Mental Hygiene from the Point of View of the Child and the Adult. J. Roy. San. Inst., 50, 3: 133 (Sept.), 1929.

More Undulant Fever—Another paper covering the now familiar ground of etiology, epidemiology and laboratory diagnosis.

HARDY, A. V. Undulant Fever. J. A. M. A., 93, 12: 891 (Sept. 21), 1929.

Biology of Cancer—This paper appears to be an unprejudiced, inclusive, careful survey of the present status of our knowledge of cancer written by one who should know whereof he speaks. Beyond this the reviewer ventures no opinion.

JACKSON, H. Recent Advances in the Biology of Cancer. New England J. Med., 201, 7: 294 (Aug. 15), 1929.

Tobacco and the Heart—Out of North Carolina comes the statement that tobacco smoking has no permanent effect on blood pressure or weight. The effect of smoking is chiefly local, principally on the pharynx.

JOHNSON, W. M. Tobacco Smoking. J. A. M. A., 93, 9: 665 (Aug. 31), 1929.

Smallpox—What happens when a Massachusetts community evades the compulsory vaccination law. "Chickenpox" develops among adults. When the health authorities take a hand, they find 223 cases. Only 2 had been vaccinated and they more than 30 years before.

MACKNIGHT, R. P., and SCAMMAN, C. L. An Outbreak of Mild Smallpox in a Massachusetts Community. New England J. Med., 201, 8: 361 (Aug. 22), 1929.

Bacteria Associated with Dental Caries—Commendable restraint marks the conclusion of this report of bacteriological studies of carious mouths. Although no one has produced caries experimentally with the isolated aciduric organisms, there is yet no proof that they are not associated in some way with the disease.

MORISHITA, T. Studies on Dental Caries, with Special Reference to Aciduric Organisms Associated with this Process. J. Bact., 18, 3: 181 (Sept.), 1929.

Specificity of Scarlatinal Streptococci—From the other side of the world comes the report of the immunologic relationships between scarlatinal and other strains of hemolytic streptococci. Such widely separated studies are of value in confirming the growing knowledge of the etiology of scarlet fever.

MORIWAKI, G. The Specificity of Scarlatinal Hemolytic Streptococci. J. Bact., 18, 3: 139 (Sept.), 1929.

School Children's Eyes—Practical methods for eye examinations for young school children serve as an interesting basis for emphasizing the importance of adequate routine examinations.

RODIN, F. H. Eye Examination of School Children. J. A. M. A., 93, 12: 911 (Sept. 21), 1929.

Fertility and Economic Status—Believe it or not, poor women bear children for a longer period of years than do the richer. This is another finding from the Hagerstown Studies.

SYDENSTRICKER, E. Differential Fertility according to Economic Status. Pub. Health Rep., 44, 35: 2093 (Aug. 30), 1929.

Health Department Quarters—As a substitute for the usual corner in the cellar, adequate housing for municipal health departments is presented. Ground plans and descriptions of several plants are included.

TOBEY, J. A., and DRUMMEY, W. W. Adequate Health Department Quarters. Am. City, 41, 3: 143 (Sept.), 1929.

Urban Typhoid Fever Rates—Typhoid fever rates in the large cities have been reduced 90 per cent since 1910. Municipal sanitation and control of food supplies is largely responsible.

TOBEY, J. A. The Reduction of Urban Typhoid. Pub. Works, 60, 9 (Sept.), 1929.

Morbidity Registration Area—A tentative plan is proposed for the establishment of a National Morbidity Registration Area.

WILLIAMS, R. C. A Proposed Plan for the Establishment of a Morbidity Registration Area. Pub. Health Rep., 44, 37: 2201 (Sept. 13), 1929.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Rockefeller Foundation—During 1928 the Rockefeller Foundation, according to its annual report, in disbursing from income and capital $21,690,738: (1) contributed to the development of medical sciences through provision of funds for land, buildings, operation, or endowment for 18 medical schools in 14 countries; (2) provided for the support of the Peking Union Medical College; (3) made minor appropriations for improving premedical instruction in China and Siam, for operating expenses of 17 hospitals in China, and for laboratory supplies, equipment, and literature for European medical centers which are still feeling the after-effects of the War; (4) through small grants assisted certain departments of medical schools in France, Italy, and Ireland which offer exceptional facilities for graduate study; (5) continued to contribute towards the advancement of the biological sciences in institutions in 4 countries; (6) assisted the development of professional public health training in 8 schools and institutes in 7 countries and in 12 field training stations in the United States and abroad; (7) gave aid to 15 nurse-training schools in 10 countries; (8) helped Brazil to combat a new outbreak of yellow fever; (9) continued studies of that disease on the West Coast of Africa; (10) took part in malaria control demonstrations or surveys in 6 of the American states and in 18 foreign countries; (11) continued contributions toward the emergency budgets of 85 county health organizations in 7 states of the Mississippi flood area; (12) aided the governments of 21 countries in fighting hookworm disease; (13) gave funds to organized rural health services in 191 counties in the United States and toward state supervision of such services in 14 states in this country, and assisted in local health work in 23 foreign countries; (14) aided in the establishment or maintenance of certain essential divisions in the national health services of 23 foreign countries and in the state health departments of 19 American states; (15) provided, directly or indirectly, fellowships for 802 men and women from 46 different countries, paid the traveling expenses of 61 officials or professors making study visits in the United States or abroad and provided similar opportunities for 127 nurses and other public health workers; (16) contributed to the work of the Health Organization of the League of Nations through the support of international interchanges of public health personnel and the development of a world-wide service of epidemiological intelligence and public health statistics; (17) lent staff members as consultants to many foreign governments; (18) made surveys of health conditions or of medical or nursing education in 5 countries; (19) collaborated with the Rockefeller Institute for Medical Research in field studies of respiratory diseases and verruga peruana; (20) assisted in mental hygiene projects in the United States and Canada, in demonstrations in dispensary development, research, and teaching in hospitals and clinics in New York City, and in numerous other undertakings in public health, medical education, and allied fields.

Some of the things which have been done to combat disease during 16 years are as follows: Temporary antihookworm campaigns in southern United States have been broadened into permanent official rural health organizations, modest, but complete. Similar developments have been aided in many tropical and semitropical regions. Else-

where local health machinery has been created or reorganized with foundation help. Malaria has been studied more fully, and methods of control have been worked out at home and abroad. Yellow fever has been forced to retreat from Mexico and Central America and from Northern South America. It is now to be found only in Brazil and West Africa. A wartime antituberculosis organization built up with foundation aid in France has been wholly taken over by the French and is being incorporated into a general public health service.

Schools or institutes of public health have been created or extended with foundation funds at the Johns Hopkins and Harvard Universities in the United States, and in Toronto, London, Prague, Warsaw, Budapest, Belgrade, Zagreb, and Sao Paulo, Brazil. Pledges have been made toward similar institutions in Angora and Calcutta. Further aid has been given to the training of health officers through participation in the maintenance of field training stations, through support to the League of Nations' plan of international study tours by health officials, and through the granting of fellowships.

Brookline, Mass.—The Brookline Board of Health presents an account of its activities for the year ending December 31, 1928, in a 50-page report. It is a satisfaction to note from the table of expenditures that substantial amounts of money have been expended in 1928 and are recommended to continue preventive work in 1929. Among these activities are immunization against diphtheria, the vaccination clinic, the school of bodily mechanics, the dental clinic, medical inspection in the schools and especially the work of the health nurses, and the clinics at the health center.

The city reports a death rate (corrected for residence) of 11.55 per 1,000 population as compared with 11.06 in 1927. Diseases of the heart (128), cancer (81), and cerebral hemorrhage (60) are the leading causes of death; cancer showing a 30 per cent increase over the 1927 figure. The number of cases of diphtheria has decreased considerably since preventive work along this line was begun in 1923. During the 5 years previous to 1923 there were 248 cases with 11 deaths, as compared to 46 cases with no deaths in the 5 years subsequent to this date.

A table showing causes of absence of pupils from the public and parochial school, as ascertained by the nurses in 1928, indicates that "colds and coughs" with 314 cases, followed by "digestive disturbances" with 121 cases, lead the list. There were 749 absences caused by illness in contrast to 313 absences due to non-sickness.

Brookline is not without its health publicity. Its *Health Bulletin* is published quarterly and distributed to every house in the city by the Police Department. "We believe it is serving the purpose of promoting education in health matters, of informing residents of the quality of the milk sold by the various dealers and of giving publicity to the various activities of the department."

Milwaukee, Wis.—The section dealing with public health activities is one of 10 sections comprising the entire 1927 report of the Common Council of the city of Milwaukee. The report, printed on paper 8" × 10", is furnished with an excellent table of contents and each section is subdivided by the use of heavy type, headings and subheadings.

The general death rate of the city was 10.4 per 1,000 population in 1927, and it is stated that Milwaukee's average death rate for the last 5 years is not excelled by any other large city.

The infant mortality rate was the lowest ever experienced in the city, being 64 per 1,000 live births.

Attendance at the 18 child welfare clinics has continued to increase materially, being 25,679 in 1927 as compared to 10,588 in 1923. There has been an attendance of 3,109 preschool children at the clinics, while 12,835 children of preschool age were visited in their homes. Because of the increase of 4 part-time physicians, the number of pupils examined by each physician has been decreased from 4,431 in 1926 to 3,878 in 1927. Physical examinations of 67,673 school children were made by these school physicians and 58,569 defects with 23,769 corrections were recommended.

There has been marked improvement in the water supply during the year, due to 3 factors: (1) the sewage disposal plant, (2) improved methods of chlorination, and (3) development of better laboratory technic.

Many additional requirements have been imposed upon milk producers. All dairy firms are required to provide mechanical capping of bottles; orders were issued requiring the use of an approved closed-top pail for milking; all producers were required to cool properly their milk before shipping to stop the growth of bacteria; and a set of rules and regulations for the proper production and handling of milk and cream was prepared by a committee representing the producers, the dealers and the health department.

Syracuse, N. Y.—The *Story of the Year* gives Syracusans: (1) information on the work done and money spent by their city government, and (2) means of offering suggestions for improving the services of the city. An organization chart of the city on the inside cover is followed by a letter from the Mayor and a 3-page statement of accomplishments of 1928, and needs of the near future. The report is effectively illustrated with photographs, charts, and graphs, with a few brief summary tables.

From the health section it is learned that 2.1 per cent of city expenditures were for conservation of health, the total amount being $279,347. The first full-time health commissioner was appointed in 1928. From a total of 45 full-time and 33 part-time employees in 1923, the personnel of the department has been increased to 94 full-time and 37 part-time employees in 1928.

A bureau of health education has been established, the nursing service has been changed from the specialized to the generalized educational form, clinic sessions have increased, and new activities have been added, such as those for crippled children, dental hygiene, prenatal and preschool services. The per capita expenditure from city funds was $1.40 and from the Milbank funds, 27 cents. This does not include medical inspection in public schools, which is under the Board of Education, amounting to 38 cents per capita.

Ninety-six per cent of all births were cared for by physicians, 66 per cent occurring in hospitals. The infant mortality rate was 58.9 per 1,000 births, while the tuberculosis mortality rate was 61.2 per 100,000 population. The ratio of reported tuberculosis cases per annual deaths was 3.2 for the year. In 10 well baby clinics, 1,195 infants were registered as having made 6,004 visits, 32 field nurses gave generalized nursing service to all the bureaus needing it.

NEWS FROM THE FIELD

COFFEE, TEA AND TOBACCO USERS

FORTY-five per cent of the male members of the freshman class at the University of Illinois last year and 21 per cent of the female members denied the habitual use of coffee, tea and tobacco. Only 30 per cent of the male members of the class professed to be users of tobacco while 50 per cent drank coffee and 20 per cent tea.

FLOATING AND SEASIDE HOSPITALS

THE Floating Hospital and the Seaside Hospital, both activities of St. John's Guild, New York, N. Y., closed their season on September 7. The Floating Hospital made 53 trips and carried 44,838 children and their mothers. Seaside Hospital in its three months' season admitted and discharged 805 children, a total service of 15,556 hospital days. About forty tonsils operations a week were performed.

WHY WHOOPING COUGH IS PREVALENT

DR. John P. Koehler, commissioner of health of Milwaukee, Wis., ascribes the failure to control whooping cough largely to the practice of allowing well children to play with coughing children. Other causes, he says, are late diagnosis and late report to the health department by the physician, the ignorance of some parents who do not "believe in" contagion, objection to having homes placarded, failure to prosecute infractions of the law, and public indifference.

ELIMINATING DIPHTHERIA IN CHILDREN'S INSTITUTIONS

AT Mooseheart School, Mooseheart, Ill., there has been only one case of diphtheria since 1920, though the average number of children in the school during that time exceeded 1,000. The resident physician ascribes this record to the fact that every child entering the school since September, 1919, has been immunized with diphtheria toxin-antitoxin. The same practice is carried out at the Soldiers' Orphans' Home at Normal, Ill., which has an average of 700 children, and no case of the disease has developed in more than three years.

787 COUNTIES NOW "FREE" OF TB CATTLE

ON September 1 there were 787 counties, located in 33 states, which had been declared by the U. S. Department of Agriculture to be "modified tuberculosis-free accredited areas." In order to receive such designation a county must have had all of its herds of cattle tuberculin tested and the extent of tuberculosis among the cattle in the county must not exceed five-tenths of 1 per cent. In all cases the cattle which react to the tuberculin test are removed and condemned for slaughter. The total of 787 counties represents a gain of 219 counties in the last 12 months. In addition to the counties, 32 towns in Vermont were designated as modified accredited areas in the course of the year.

DR. PLATT GOES TO HONOLULU

PHILIP S. Platt, Ph.D., will sail from San Francisco, Calif., November 6 for Honolulu to accept the position of Director of the Palama Settlement. He has resigned as Executive Secretary of the Associated Out-Patient Clinics Committee and assistant director of the New York Tuberculosis and Health Association, New York, N. Y.

NEW ORLEANS HOSPITAL

COMPLETION of the Catherine Cordes Voss addition to the Miles amphitheatre of Charity Hospital here is announced by Dr. Arthur Vidrine, superintendent. Three new operating rooms, three new sterilizing rooms, and the renovation of older rooms and equipment in the building to which the addition has been made, were provided at a total cost of $62,500.

VACCINATION AGAINST TUBERCULOSIS IN FRANCE

IN a recent circular the Minister of Hygiene of France asks the prefects to take the necessary measures for increasing the use of the antituberculosis vaccine and quotes the favorable opinion on this subject expressed by members of the section on hygiene of the League of Nations and of the French Academy of Medicine.

The circular directs the prefects to ask the local branches of the National Association against Tuberculosis and the local public health authorities to organize a system of preventive vaccination against tuberculosis of newborn infants and older children. The vaccination, however, is to be optional; the decision in each case is to be made by the attending physician.

INTERNATIONAL

FIFTH International Congress of Physical Therapy, Liège, Belgium, will be held September 4–8, 1930.

The congress will consist of 5 sections: (1) Kinesitheraphy, including physical education; (2) radiology (roentgen therapy); (3) hydrology, climatology and thermotherapy; (4) electrology; (5) actinology.

Chairman of committee on organization is M. de Munter, professor à la Faculté de Médecine de l'Université de Liège, Liège, Belgium.

PERSONALS

R. K. GALLOWAY, M.D., director of the Carlisle County Health Unit, Bardwell, Ky., has been given a Fellowship from the International Health Board, and will use it to take a year's work at Harvard School of Public Health.

DR. FORREST J. PINKERTON, Honolulu, was made president and Dr. Archibald N. Sinclair, Honolulu, secretary, at the annual meeting of the Hawaii Territorial Medical Association, at Honolulu.

DR. JAMES H. FLYNN has been appointed health commissioner of Troy, N. Y., to succeed the late Dr. William J. Fleming.

DR. ESMOND R. LONG, professor of Pathology of the University of Chicago, has been appointed the new editor-in-chief of the *Journal of Outdoor Life*, the official publication of the National Tuberculosis Association.

DR. SAMUEL A. LEVINSON has been elected president of the Chicago Tuberculosis Association for 1929–1930.

DR. LEWIS WADE HEIZER, formerly of the Cincinnati, O., Health Department, is the new medical inspector of Watertown, N. Y.

CONFERENCES

Nov. 4–7, 8th Annual Meeting of the American College of Therapy, Chicago, Ill.

Nov. 11–13, National Society for the Prevention of Blindness, St. Louis, Mo.

Nov. 20–22, Southern Medical Association, Miami, Fla.

Dec. 3–5, 7th Texas Sanitary Short School, Edinburg, Tex.

Dec. 6–7, New Jersey Public Health and Sanitary Association, Asbury Park, N. J.

Dec. 25–Jan. 1, Society of American Bacteriologists, Ames, Ia.

Jan. 27–30, 12th Texas Water Works Short School, Abilene, Tex.

Malnutrition, Marasmus Infantile Atrophy Athrepsia

Maltose is the Most Satisfactory Carbohydrate to Increase Body Weight

Maltose is the Predominating Carbohydrate in Mellin's Food

To improve conditions that may be properly grouped under the above-mentioned terms, the first thought of the attending physician is an immediate gain in weight, and the second thought is to so arrange the diet that this initial gain will be sustained and progressive gain be established. Every few ounces gained means progress not only in the upward swing of the weight curve, but in digestive capacity in thus clearing the way for an increasing intake of food material.

As a starting point to carry out this entirely rational idea, the following formula is suggested:

Mellin's Food	**8 level tablespoonfuls**
Skimmed Milk	**9 fluidounces**
Water	**15 fluidounces**

This mixture furnishes 56.6 grams of carbohydrates in a form readily assimilated and thus quickly available for creating and sustaining heat and energy.

This mixture supplies 15.5 grams of proteins for depleted tissues and new growth, together with 4.3 grams of mineral salts which are necessary in all metabolic processes.

These food elements are to be increased in quantity and in amount of intake as rapidly as continued improvement is shown and ability to take additional nourishment is indicated.

A pamphlet devoted exclusively to this subject and a liberal supply of samples of Mellin's Food will be sent to physicians upon their request.

Mellin's Food Company, Boston, Mass.

The Hemolytic Streptococci and Antistreptococcus Serum in Scarlet Fever*

AUGUSTUS B. WADSWORTH, M. D., FELLOW A. P. H. A.

Director, Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

THE relationship of the hemolytic streptococci to scarlet fever forms the basis upon which rests the serum therapy of the disease. Although the important work of Dochez and the Dicks started from the premise that a particular group of streptococci was the specific incitant of scarlet fever, previous experience with the identification of species in general and the streptococcus in particular, especially when based upon the variations in the agglutination reaction as it was in the beginning, suggested the possibility that the premise might be false, despite the fact that the results of their work had such unquestionable practical value in the treatment and prevention of the disease. The basis for the differentiation of a specific incitant of the disease seemed quite inadequate and untrustworthy. A thorough study was therefore made of the streptococci isolated from many different related and totally unrelated infectious processes. At the time this work was started the only method available for studying the toxin and antitoxin was the intracutaneous test on the human subject. This appeared to be an insurmountable obstacle to a very extended study until the goat was found to be a satisfactory substitute.

Since the reports published in 1926 on the study of the toxins of approximately 100 strains of streptococci from infections diagnosed as scarlet fever, and 100 strains from other infections, about 90 ad-

* Read before the Laboratory Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

ditional strains from each of these sources have been tested with very similar results. It has been found that over 85 per cent of approximately 200 strains of streptococci from cases of scarlet fever, and about 70 per cent of 200 strains of streptococci from other infections produced toxins which induced definite skin reactions in goats. Approximately 65 per cent of all these toxins, irrespective of whether the source of the strain was a scarlet or non-scarlet infection, were neutralized by a standard antitoxic goat serum produced against the Dochez N. Y. 5 strain, while 35 per cent were not.

It is evident that even if by any chance there is a particular streptococcus which is the specific incitant of scarlet fever it is impossible to differentiate it by any of the known tests.

In a paper presented before the New York Division of the Society of American Bacteriologists in November, 1925, which unfortunately was not published, I suggested that it might

> . . . perhaps border on the quixotic to question the necessity of differentiating a particular streptococcus as the incitant of scarlet fever in order to fulfil Koch's postulates. The attempts to distinguish the scarlet streptococci from other forms have led to important discoveries, but they are largely based upon the agglutination and the absorption-of-agglutinins tests which have not been found to be altogether reliable in the separation of the strains of bacterial species, less so possibly with the streptococci than with any other species . . . possibly the importance or necessity of differentiating the streptococcus into the scarlet and non-scarlet strains has been greatly overemphasized in some of the work. If the etiological relationship of the streptococcus can be said to be reasonably established—and it appears to be—is it necessary to differentiate a particular streptococcus as the incitant? Do we really know enough about toxin production in general among bacterial species, or the action of any of the bacterial toxins in the tissues, to reach a final conclusion? In my own experimental work there are a number of observations, some published, others awaiting further analysis, which differentiate the toxin production of the pneumococci and the streptococci from their parasitic adaptation in infection quite similarly if not quite so clearly as we now recognize it in scarlet fever. Moreover, observations are accumulating in my own experience to indicate that special conditions of tissue susceptibility underlie the manifestations of toxic action.
>
> Experiments on the experimental induction of pneumonia in the partially immunized rabbit early emphasized the importance of tissue susceptibility. The most striking illustration, however, was observed in some unpublished experimental work which for ten years or more has been awaiting further experimental analysis:
>
> Rabbits inoculated with the pneumococcus usually die promptly with a bacteremia without any macroscopic or microscopic change in the tissues and organs of the body beyond those of congestion. Occasionally there are signs of hemorrhagic extravasation, but this is rather exceptional. When the streptococcus possesses a sufficient degree of adaptation or virulence, the results are similar, but if the virulence is extremely exalted the occurrence of hemorrhagic reaction is per-

haps more common. Under certain conditions of susceptibility, at present possibly quite indeterminate, the reaction may be quite a different one. In rabbits inoculated intravenously with a culture of highly virulent pneumococci directly from the heart blood of a dead animal, and 2 to 4 hours later treated with antipneumococcus serum, the animals, with varying febrile reaction, which appear normal in their cages may suddenly, in a few seconds, die in typical anaphylactic shock. In one experiment with 4 such animals inoculated at 12 o'clock noon, all 4 died in this manner between 10 and 10:20 p.m. In a larger series, the animals died irregularly at different periods up to 30 or 36 hours. At autopsy the hemorrhagic condition was extreme in the various organs and tissues. The lymph nodes and the tracheal mucous membrane were almost black.

The development of endocarditis during immunization of horses for therapeutic serum affords striking evidence of the selective action of the toxin on the blood vessels, and possibly suggests a relation to some phase of the development of immunity.

I recall also a case in private practice of nephrolithiasis and purpura hemorrhagica associated with streptococcus infection. The patient was sent to me by a surgeon for diagnosis, having travelled for ten years to various health resorts abroad on account of her condition. The urine was heavily laden with pus, but there were no other symptoms, and no febrile reaction. A full description of this case appears in the *Journal of the American Medical Association,* 1918.[5] The purpura hemorrhagica in this case was one of the most marked examples I have seen—injury so slight as to be unnoted, giving rise to extensive purpura. Streptococci were isolated and demonstrated filling the pus cells. There was no cystitis, the focus being in the kidney, associated with a large calculus. Vaccines were prepared from the streptococcus culture in human blood broth by centrifugalization, filtration of the culture fluid, and suspension of the sediment heated to kill the cocci. The vaccine of killed cells when injected caused no unusual reaction. The culture filtrate, however, gave rise to extensive hemorrhagic reaction, resembling the purpura, which diminished steadily with each injection, and after complete immunization the patient has been free from the purpura.

This appears to me striking evidence of the selective action of the streptococcus toxin and suggests special conditions of susceptibility underlying the action of these toxins.

More recently this point of view has aroused considerable interest and stimulated experimental studies in this country and abroad; for example, those of Stevens with Dochez and others.[6-10] The studies of the action of toxin and its neutralization by antitoxins in different animals by Miss Kirkbride and Miss Wheeler have brought out many observations which are of practical significance in considering the development of scarlet fever, because they relate so definitely to the variation in the action of toxin according to the different phases of tissue susceptibility. In many respects the toxins of the streptococcus obtained from different sources proved similar when their toxicity was tested in different animals and when this toxic action was neutralized by a standard serum. The similarity was so general when a strain

with a broad antigenic value was used as to make it difficult or impossible to differentiate these streptococci from different sources into specific or special groups; yet with closer study some very marked differences were noted, even in the toxins which were apparently so similar. For example, toxins when tested in one individual apparently had a similar action varying only in degree, but when tested on another individual or on different animals, one was toxic and the other without action. In other words, there are phases of tissue susceptibility essential to the action of the toxin which may be present in one individual and not in another. This is an important fact when one considers the development of scarlet fever, and presents also certain difficulties in testing tissue susceptibility by the intracutaneous test with one toxin, and stresses the importance of selecting a standard toxin of sufficiently broad action to give results of practical value. Moreover, the toxins are apparently complex; one may be completely neutralized by an antitoxin whereas another may be only partially neutralized by this antitoxin, and it appears that these differences in reaction are due to different activities of the toxin, because the activity which is not neutralized by one antitoxin is neutralized by another produced by a different strain or possibly in a different animal. Toxins which are apparently similar when neutralized by one antitoxin are thus shown to be quite dissimilar when tested with another produced by different strains of the streptococcus or by the same strain in a different animal, and also when tested in different animals or in different persons. The results of this work thus have a very important bearing on the specific etiology of scarlet fever and suggest the conditions underlying the development of the disease—possibly explain the reason why scarlet fever often fails to develop after exposure when expected, or appears when least expected.

The preparation of different antitoxins afforded an excellent opportunity for the comparison of the different strains as antigens. The valency of the antitoxins prepared with some strains was much more limited than that of antitoxins prepared from other strains. Moreover, the potency varied. The selection of a standard strain for the purpose of comparison or for the preparation of therapeutic serums, therefore, is extremely important. The Dochez N. Y. 5 strain has proved without exception the most satisfactory strain from the standpoint of polyvalency and antigenic potency. Strains were found which produced a stronger toxin but these failed to produce serum of higher potency or as great polyvalency. The Dick strains I and II were not satisfactory. In no horses we have tested has it been possible to obtain a serum of sufficient potency for distribution. The

high potency and broad polyvalency of the serums produced by immunization of horses with the Dochez N. Y. 5 strain proved so much greater than that of any other serum that in the preparation of the therapeutic serum there appeared to be no necessity for the addition of other strains—rather the contrary.

Methods of immunization differ in that the Dicks have recommended immunization with the toxin, whereas Dochez has emphasized the importance of injecting subcutaneously living virulent cultures into a mass of agar. Immunization with the toxin alone has not in our experience produced a serum of sufficient potency for the treatment of the disease. It is necessary to inject living cultures to obtain the most potent serums.

Production of serums of the highest potency and polyvalency has been greatly handicapped by the difficulties of standardization, and also greatly complicated by the selection of different strains for immunization of the horses. With many of these strains standardization has only been practicable on human subjects. The serums for distribution have in a great majority of the instances been concentrated. Standardization is much more difficult when it has been concentrated. We have been particularly fortunate in having selected a single strain which has not only lent itself most satisfactorily to the immunization of horses but can be standardized on the goat as well as the human subject; hence it has been possible to follow the progress of the immunization of the horses closely, and bleed at opportune periods of immunization. Finally, the potency and polyvalency attained in this monovalent serum have been such as to render concentration quite unnecessary, and in fact a questionable procedure. Serums of the highest potency have scarcely been bettered by concentration.

The results of comparative tests which appeared in a recent publication of the *Journal of Hygiene*[11] very strikingly illustrate the points which I have brought out. In these tests the therapeutic serums from a number of laboratories were obtained and tested. With one exception these were all concentrated, and nearly all of them had a potency less than half that of our standard control serum. The standards for serums available for treatment have been advanced within the last two years, as a result of the distribution of a standard or control serum for purposes of comparison to the different producing laboratories, but the minimum federal standard of 200 units seems totally inadequate, and for some time it has been our practice to distribute no serums of less than 600 units, 30,000 skin-test doses, and the majority have approximated 800 units per c.c. The commercial

and other serums which are distributed under federal license are labeled as to potency, and the clinician can very readily estimate the potency of any serum by dividing the total units or skin-test doses by the number of cubic centimeters in the dose. In the literature the comparison of the dosage, when reported, in skin-test doses and also in cubic centimeters, indicates a rather low potency approximating the minimum federal standards.

The action of the serum in the treatment of the disease has been most carefully determined by Blake in his early work.[12-14] These studies point out very clearly the limitations in treatment. He was able to demonstrate the presence of toxin in the blood during the earliest stage of the disease and also the neutralization of that toxin by the administration of serum in the uncomplicated case. In the later stages of the disease and in cases complicated by extension of the infectious process the toxin was not so completely neutralized by the serum and the treatment was not so effective.

Reports on the clinical treatment of scarlet fever have now accumulated so there are large series of cases in the literature. The potency of the serums which were used is not clearly stated in many articles. One can only infer from the dosage when recorded, or from experience in testing representative samples of these serums, that the potency was very low or might even have been entirely lacking. We have found serum in which we could not detect any antitoxic activity although it was labeled to neutralize 30,000 skin-test doses per c.c.

There are different points of view regarding the practical value of serum therapy in scarlet fever. The disease is so much milder than formerly; there are so many cases which recover quickly and spontaneously without complications; and so many others of a serious character with complications which do not respond definitely to the serum treatment, that some clinicians question its practical value. The results, however, are so striking when cases are treated early that the great majority of clinicians strongly advocate its use.

Apparently many treat only the selected cases of more serious types. The seemingly mild onset in a few of the complicated and serious infections constitutes a real difficulty because it is impossible to determine this fact at the time that treatment should be given. If such favorable results were obtained with the early serums one would naturally expect the more potent serums to be even more efficacious. Certainly it is inconceivable that the early administration of serums of the highest potency should not be a very important factor in the prevention of the unforeseen development of complications, which is really the crux of the problem. Thus it is obviously

owing to the fact that the disease has become, in such a vast majority of cases, of a mild type, that the value of serum therapy is not brought out by comparative statistics. Delayed diagnosis and treatment also tend to make the conclusions from these statistics untrustworthy. One is forced to rely upon the study of the effect of serum in individual cases, particularly the complicated and fatal cases.

Reports have been received on the treatment of 587 cases of scarlet fever with our monovalent antistreptococcus serum, unconcentrated, which titers from 600 to 800 units per c.c., or 30,000 to 40,000 skin-test doses. The individual dose approximated 10 c.c. or 6,000 to 8,000 units. These cases have been treated under various conditions, and on account of incomplete data it is impossible to classify them into groups which could be considered as having received satisfactory treatment as contrasted with those which received unsatisfactory treatment. The cases have been grouped according to the type of the disease in Table I.

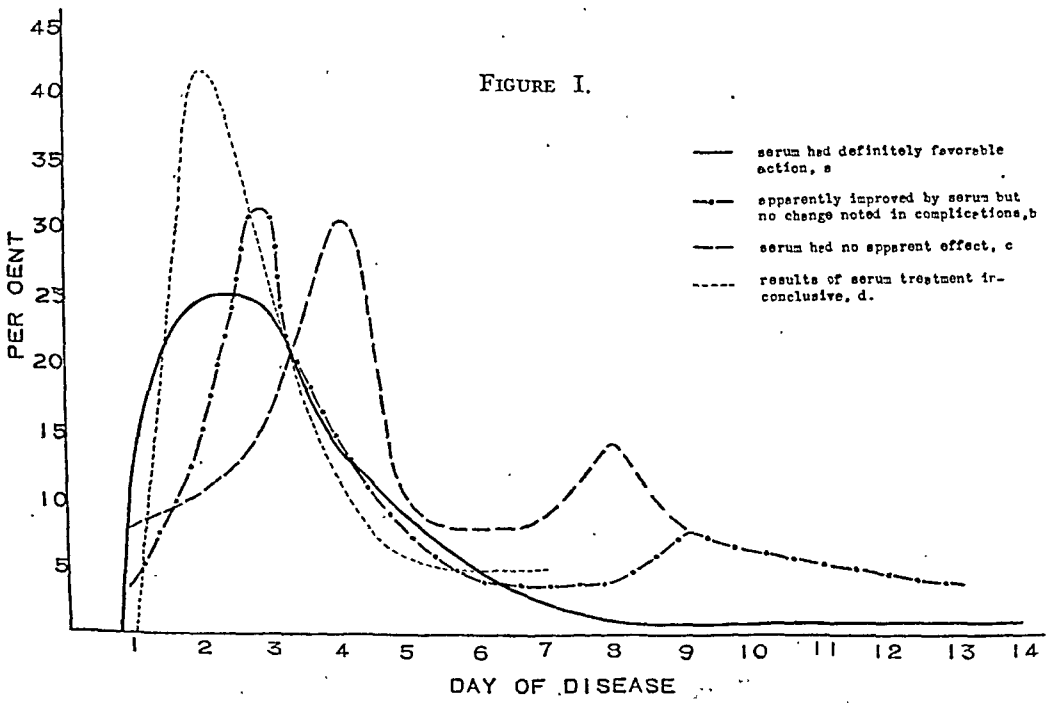
TABLE I

CLASSIFICATION OF CASES OF SCARLET FEVER TREATED WITH NEW YORK STATE UNCONCENTRATED ANTISTREPTOCOCCUS SERUM

	Total		Mild		Moderate		Severe	
	No.	%	No.	%	No.	%	No.	%
Cases treated	587		103	18	282	48	202	34
Fatal cases *	27	5	0	0	3	11	24	89
Recovered cases	560	95	103	18	279	50	178	32
Recovered cases in which complications were present	149	25	15	10	55	37	79	53
a. serum had definitely favorable action	92	62	10	11	34	37	48	52
b. apparently improved by serum but no change noted in complications	25	17	3	12	9	36	13	52
c. serum had no apparent effect	13	9	0	0	6	46	7	54
d. results of serum treatment inconclusive	19	13	2	10	6	31	11	58

* 18 cases with complications
9 cases without complications
1 very severely toxic
2 fulminating
6 serum administered within 24 hours antemortem (2 anaphylactic shock)

In practically all of the cases which recovered the effect of treatment is such as has been very generally described, fading of rash, fall in temperature and pulse rate, relief of symptoms due to toxic condition, and marked subjective signs, 12 to 48 hours after administration of serum. The proportion of complicated cases which recovered —149 of the total 587 cases—suggests that physicians had selected the severe type of case for serum treatment. Practically all of the



27 fatal cases were infections with complications, or were of the fulminating or malignant type, or were treated late in the disease, in some instances shortly before death. The fact that there were 176 complicated or fulminating cases out of 587, and the rather high mortality of 4.59 per cent are further indications of the severe type selected for treatment. However, that there were 149 cases with complications which recovered is of interest, especially as some of these cases were severe types and evidently had an extension of the infectious process so that they were not simple toxemias.

Of the 149 cases which had complications and recovered, 136 improved under serum treatment. There were no definite signs of improvement in the remaining 13. Of the 149 recoveries with complications, 34 had otitis media, 5 mastoiditis, 19 cervical adenitis, and 9 some gland involvement, 2 involvement of the salivary glands, 2 endocarditis, 4 arthritis, 6 rheumatic affection of the joints, 14 varying degrees of nephritis, 7 abscesses (neck, tonsils, submaxillary glands, etc.), 1 axillary cellulitis, and the remaining had minor extensions of the process.

There were 13 cases in which the serum had no apparent effect on the course of the disease. The character of the complications, the late stage at which treatment was started, or the inadequate dosage,

DAY OF DISEASE ON WHICH SERUM TREATMENT FIRST ADMINISTERED IN RECOVERED CASES WITH COMPLICATIONS

FIGURE I.

accounts for many but not all of these. There is always a varying but definite number of cases of all infectious disease which do not respond to serum treatment. The cases which did not respond to treatment, whether they recovered or died, are of such interest that their histories have been summarized.

SUMMARY OF THE RECOVERIES THAT APPARENTLY DID NOT RESPOND TO TREATMENT (13)

1. F., age 5. Onset, 2/20; rash, 2/23. Symptoms severe: acute conjunctivitis, nephritis, otitis media; measles. 2/28, 7,200 to 8,000 units serum intramuscularly; infection of eye 6 days after onset. No apparent results from serum.
2. F., age 43. Onset, 3/28; rash, 3/31. Symptoms moderate: discharging ears, cervical glands tender and swollen. 3/31, 24,000 units serum intravenously; 3,000 units diphtheria antitoxin on admission. Results of serum "none."
3. M., age 8. Onset, 12/24; rash, 12/25. Symptoms moderate: adenitis, arthritis, endocarditis. 12/30, 6,000 units serum intravenously. Patient recovered fully; had typical desquamation. Complications developed several days after administration. Serum had apparently no effect on general symptoms.
4. F., age 5. Onset, 4/2; rash, 4/3. Symptoms moderate: cervical adenitis. 4/5, T. 101°, 6,000 units serum. 4/6, T. 103°; 4/8 to 4/11, 102°; 4/12, 103° (earache). 4/14, T. normal.
5. F., age 7. Admitted to hospital, 4/26. Symptoms severe: bilateral mastoid (operated), double otitis media, arthritis, glands, infected finger. 4/26, T. 105°, 12,000 units serum intramuscularly. 4/27, T. 102° rising to 105° in p.m.; profuse nasal discharge; 12,000 units serum intravenously and 12,000 units diphtheria antitoxin. 4/28, T. 101°, 18,000 units serum intravenously. "No apparent effect from serum."
6. M., age 6. Onset, 7/19; rash, 7/20. Symptoms severe: swollen glands, abscess on neck and right forearm; patient cyanosed on admission; pulse imperceptible. 7/21, T. 105°, 6,000 units serum intramuscularly. 7/22, T. 101°. 7/23, T. 104°, 6,000 units serum intramuscularly. Results of serum, "none."
7. F., age 33. Onset, 12/13; rash, 12/15; hemolytic streptococci isolated. Symptoms moderate: sinusitis. 12/15, 12,000 units serum; 12/16, no improvement; 12/17, T. normal, rash fading; 12/19 to 12/26, persistent temperature.
8. F., age 2½. Onset, 2/9; rash, 2/10. Symptoms severe: otitis, glands. 2/16, 2/17, 2/18, 6,000 units serum each day. T. 102° to 104° during serum treatment. Results, "none."
9. F., age 8. Onset, 4/29; rash, 5/1. Symptoms severe: lobar pneumonia, double otitis media. 5/2, 6,000 units serum intramuscularly. "No apparent effect."
10. F., age 8. Onset, 4/16; rash, slight 4/17 and 4/18, definite 4/19. Symptoms moderate: lymphadenitis both sides neck. 4/19, 7,200 units serum. T. returned to normal on 6th day after administration of serum.
11. M., age 3. Onset, 2/21; rash, 2/26, lasting 6½ days. Symptoms moderate: otitis on 6th day. T. advanced from 101° to 104°. 2/28, 3,200 units serum.

3/1, 1,600 units serum intramuscularly. Discharge from ears for 1½ months.

12. F., age 6. Onset, 1/8; rash, 1/9; streptococci isolated from throat culture. Symptoms severe: nephritis, otitis media, mastoiditis, rheumatic syndrome, urticaria. 1/11, 6,000 units and 1/12, 600 units serum intramuscularly. Serum had apparently no effect.
13. F. Onset, 3/28 (operated for empyema on 3/28); rash, 3/30. Symptoms severe: empyema. 4/2, 6,000 units serum; serum rash, considerable pains; very toxic. Serum apparently had no effect.

SUMMARY OF THE FATAL CASES (27)

1. M., age 3. Onset, 2/5, " with sore throat and convulsions; T. 105.6° (rectal); angina marked on 3d day; comatose throughout illness; systolic murmur at apex of heart began 2/10, also middle ear at same time." 2/11, 5 p.m., 800 to 1,200 units serum subcutaneously; dose repeated at 11 p.m. with " no visible change." Death, 2/13.
2. M., age 25. Clinical diagnosis: scarlet fever or erysipelas. Previous history: patient admitted to hospital 10/4/24 with gun-shot wound; tetanus antitoxin (1,500 units) given at this time. 6/10/25, while wound was still discharging, left hospital to visit his children at orphanage; scarlet-like rash appeared; T. 104°; 0.2 c.c. antistreptococcus serum intracutaneously in each of 2 areas produced local blanching in 5 hours; 1,600 units then given intravenously and 3,200 intramuscularly—marked toxemia; condition not favorable. Following morning rash entirely disappeared, T. 100°; patient comfortable and improvement striking. Death several weeks later from septicemia.
3. F., age 42. Had nursed daughter who had developed scarlatinal rash and otitis media following tonsillectomy. Daughter's rash disappeared 24 hours after administration of 7,200 to 8,000 units of serum; other symptoms persisted but she finally recovered. Mother developed rash day or two after daughter, with marked angina of throat, also subacute arthritis becoming more acute. Serum produced local blanching of rash; 7,200 to 8,000 units given intramuscularly; rash disappeared in 24 hours, otherwise no change; 2 days later a subacute erysipelas became rapidly acute and fatal in about 48 hours.
4. M., age 19. Onset, 1/27; rash, 1/29. Symptoms severe: angina and marked toxemia. 1/31, 12,000 units serum intravenously, 6,000 intramuscularly; later that evening 18,000 units intravenously. T. dropped; patient seemed less delirious, but died 2/1.
5. M., age 2. Onset, 11/5; rash, 11/6. Symptoms severe. 11/10, less than 4,000 units serum. Death, 11/11.
6. F., age 23. Onset, 1/28; rash, 1/29. Symptoms severe. 2/2, 4,000 to 8,000 units serum intramuscularly. Death, 2/3.
7. M., age 2. Onset, 2/17; rash, 2/18. Symptoms severe: profuse nasal discharge. 2/22, 12,000 units diphtheria antitoxin and from 4,000 to 8,000 units antistreptococcus serum intramuscularly. Death, 2/26.
8. M., age 54. Onset, 1/8. Symptoms severe: oedema of larynx. 1/12, 6,000 units serum. Died following day.
9. F., age 4. Onset, 2/9; rash, 2/10. Symptoms moderate. T. 102°. 2/11, 6,000 units serum intramuscularly; patient much improved: T. normal, P. 96. 2/16, T. 103°, acute serum rash; cervical glands enlarged and tender; T. rose

to 104°—patient seemed very sick, serum rash increased. 2/20, patient more toxic, nauseated and vomited; considerable mucopurulent discharge in throat. Death, 2/23, probably from laryngeal edema.

10. M., age 3. Onset, 12/24; rash, 12/27. Symptoms severe: malignant type. 12/28, 4,000 to 8,000 units serum intramuscularly. Death, 12/30.
11. M., age 7. Onset, 7/1; rash, same day. Symptoms moderate. Approximately 6,000 units serum intramuscularly; child apprenhensive, struggled. Two minutes after administration of serum, child had convulsion; respiration ceased; death attributed to status lymphaticus.
12. M., age 7. Onset, 7/1; rash, 7/2. Symptoms severe: double otitis media and cervical adenitis. Became very toxic on 3d day. Serum (dosage not stated) given on 4th, 5th and 6th days. Condition greatly improved for about 1 week, when severe infection of cervical glands developed with erosion of jugular vein and large artery. Death on 21st day of disease from hemorrhage and sepsis.
13. M., age 7. Onset, 7/1 with profuse rash. Symptoms severe: cervical adenitis, fatal erosion of external jugular vein and lingual artery. Patient received 12,000 to 16,000 units of serum daily for 6 days beginning 3d day; general symptoms improved. Death, 2 weeks after onset.
14. F., age 39. Onset, 2/4 with rash. Symptoms moderately severe but with uncontrollable nausea and vomiting; complete suppression of urine for 36 hours. 2/6, T. 106°, 6,000 units serum; patient improved; rash faded. Death, 14th day of disease.
15. M., age 7. Onset, 2/9; rash, 2/10. Symptoms septic: marked throat conditions; first 2 days patient did not promise to be severe case but became more septic. 2/13, T. 103°, 6,000 units serum; 2/14, dose repeated; little or no improvement. Death, 2/15.
16. M., age 24. Onset, 3/7 with rash, T. 104°. Symptoms severe. (2/24, patient had operation for ruptured gangrenous appendix.) 3/8, T. 102°–103°. 3/9, 6,000 units serum intramuscularly; T. then 104°–105° and remained high; patient became delirious and died, 2/10.
17. M., age 5. Onset, 3/30 with rash. Symptoms moderate until 4/10 when they became severe: double otitis media, double mastoiditis, broncho-pneumonia, and acute nephritis. 4/11, 13th day of disease, 6,000 units serum subcutaneously; T. remained high; no improvement. Mastoid operation, 4/13. Death, 4/16.
18. M., age 26.. Onset, 1/27; rash, 1/28. Symptoms severe. History of epilepsy. 1/20, 12,000 units serum intramuscularly; dose repeated in evening. T. dropped but patient was very toxic and comatose. 2/4, pneumonia of left lower lobe developed. Death, 2/6. Autopsy: broncho-pneumonia.
19. M., age 38. Onset, 6/6; rash, 6/7. Symptoms severe: T. 104°, hemorrhagic nephritis, uremia and septicemia. 6/10, 18,000 units antistreptococcus serum and 12,000 units diphtheria antitoxin; T. fall only temporary; uremic poisoning. Death, 6/17.
20. F., age 28. Onset, 5/6; admitted to hospital, 5/10. Symptoms moderate: T. 104°; 6,000 units serum subcutaneously. 5/11–13, T. 99°–101°; 6,000 units serum intramuscularly. 5/19, type III pneumonia developed; fatal 5/28.
21. M., age 3½. Onset, 8/7; rash, 8/9. 8/12, T. 103.6°; patient unconscious; rash all over the body; 6,000 units serum intramuscularly. Death same day.

22. F., age 6. Onset, 1/8; rash, 1/9. Symptoms severely toxic: T. 105°–106°. 1/10, 6,000 units serum intramuscularly; T. dropped temporarily. Following day streptococcus pneumonia developed, T. 104°, 6,000 units serum intramuscularly, T. dropped to 102° but rose again quickly. Death, 1/16.
23. M., age 8. Onset, 4/1; rash, 4/2. Symptoms severe. 4/3, 3,000 units serum. In 10 minutes patient irrational, cyanosed, and pulseless; adrenalin had no effect. Death 15 minutes after serum injection.
24. F., age 26. Onset, 3/9; rash, 3/10. Symptoms severe: patient toxic and delirious. 3/12, 12,000 units, 3/13, 12,000 units serum intramuscularly. T. dropped from 103° to 100° following day—patient brighter and mentally clear, pulse improved. 3/15, again toxic, stuporous. 3/16, T. 105°; 12,000 units serum intravenously. 3/17, T. 106°; 18,000 units serum intravenously; T. dropped to 101°, returned to 106° within next 4 days. Death, 3/21.
25. M., age 7. Onset, 2/8; rash, 2/10. Symptoms severe: vomiting and delirium, discharge of right ear. 2/13, 6,000 units antistreptococcus serum intramuscularly; dose repeated in the evening together with 18,000 units diphtheria antitoxin intravenously. 2/14, T. dropped from 105° to 101° but returned to 103°; 6,000 units serum and 12,000 units antitoxin intravenously. 2/19, serum rash. Death, 2/22.
26. F., age 12. Onset, 5/3; rash, 5/5. Diagnosis: scarlet fever and nasal diphtheria. Symptoms severe: vomiting; admitted to hospital in very serious condition, toxic and cyanotic. 5/8, 6,000 units antistreptococcus and 6,000 units diphtheria antitoxin intramuscularly; in the evening 12,000 units serum and 12,000 units antitoxin intravenously; half an hour later 18,000 units serum and 12,000 units antitoxin intraperitoneally. 5/9, 12,000 units serum and 12,000 units antitoxin intravenously; in the evening 6,000 units serum and 12,000 units antitoxin; pulse improved but temporarily. Death, 5/10.
27. M., age 32. Onset, 5/6; rash, 5/7. Symptoms severe: nephritis and cardiac condition. 3,000 units antistreptococcus serum; also diphtheria antitoxin. Died in 4 days.

These fatal cases were evidently severe infections with two exceptions, 15 and 17, which had a mild onset and became complicated—very striking illustrations of the impracticability of distinguishing early in the disease a mild form of scarlet fever that does not require serum treatment. Nine of these 27 cases can scarcely be said to have had sufficient serum. Three of these, 5, 6, and 8, not only received insufficient serum but received it late, less than 24 hours before death; and another, 10, 48 hours before death. Beside these, 3 cases (1, 15, and 17) were treated late. Three (2, 12, and 13) improved under serum treatment but died later. Four (7, 19, 25, and 26) apparently had diphtheria and 3 (18, 20 and 22) pneumonia. Two cases (11 and 23) died of anaphylactic shock, in one instance attributed to status lymphaticus.

Case 3 is interesting because both mother and daughter developed the disease and were treated with serum. The daughter recovered promptly; the mother died with acute erysipelas. The serum was evi-

dently effective in one instance and not in the other. Case 9 is especially interesting because it suggests the possibility of serum sickness acting as a predisposing condition, favoring the development or extension of complicating processes.

The results of serum therapy in our experience, as recorded in the tables, correspond in general with those published by other observers. The mortality or the recovery in complicated cases depends largely upon the severity of the disease in the cases which have been selected for treatment. The small proportion of mild cases is obviously an indication that the cases treated were severe infections. A considerable number, at least 3, of the fatal cases should be eliminated on account of the fact that the quantity of serum was inadequate and was given late in the disease, 24 hours or less before death. It has not been practicable to eliminate those in which the physician delayed treatment until the prognosis had become serious or definitely unfavorable, but there is a considerable number of such cases.

One of the objections to the serum treatment of all cases of scarlet fever is the occurrence of serum sickness. The quantities of serum are such as to give rise to well marked reactions a week or 10 days after treatment. In the series there are 3 cases of anaphylaxis; 2 of them are listed in the series of fatal cases (11 and 23), 1 was diagnosed as status lymphaticus, and the other did not respond to adrenalin and died within 10 minutes after serum treatment. The third case of anaphylaxis responded to adrenalin and recovered. No history of previous sensitization was obtained. The percentages of serum sickness reported in the literature vary greatly; 30 and even 40 per cent are recorded. Whether or not this is directly proportional to the quantity of protein injected is difficult to determine. The percentages of serum sickness were high in some instances where large quantities of serum were given, but the data are inadequate to indicate the relationship between the occurrence of serum sickness and the potency of the serum used. The concentrated product does not appear to lessen the number of reactions materially, for the concentrated serums have not been of sufficiently high potency so that the dosage, and therefore the quantity of protein, could not be reduced materially. In our experience, approximately 28 per cent developed serum sickness.

Statistics indicate quite definitely some protection as a result of vaccination or active immunization with the streptococcus toxin, but this has not been altogether reliable. As a result of experience, the dosage and the number of inoculations have been increased in the hope of securing more effective protection, all of which raises a ques-

tion as to its practical value as contrasted with close observation and prompt treatment of cases as soon as they develop. Although active immunization when adequate and applicable is effective, passive immunization with serum has not received much general support—rather the contrary. Our policy has been a conservative one. We have not recommended protective treatment, save in special instances, and have questioned the practical value of its general application.

The practical results of serum therapy in scarlet fever with antistreptococcus serum produced by a streptococcus isolated from a case of scarlet fever might lend support to the view that a particular streptococcus is the specific incitant of the disease were it not for the fact that this serum is also effective in other streptococcus infections. Erysipelas was also attributed to a specific organism, but subsequent work has shown that it is impossible to differentiate the streptococcus of erysipelas. Recently special antistreptococcus serums have been produced for the treatment of erysipelas. These serums were tested in comparison with a serum produced for the treatment of scarlet fever against toxins produced by strains isolated from cases of erysipelas. Our results indicate that the antistreptococcus serum produced by the Dochez N. Y. 5 strain has an equal or even greater potency and polyvalency, and the serum used in scarlet fever has also been used in cases of erysipelas as effectively as the special antistreptococcus serum for this disease.

CONCLUSIONS

There is no definite evidence that a particular group of streptococci are the specific incitants of scarlet fever—rather the contrary. Analysis of the morphological, biological, serological and immunological characters of approximately 400 strains of streptococci from different sources fails to distinguish any distinct groups of streptococci associated with the different infectious processes incited by these organisms. The toxic action of 85 per cent of 200 strains of streptococci from scarlet fever and 70 per cent of 200 strains from other sources was quite similar when tested in goats. Approximately 65 per cent of all these toxins, irrespective of whether the source of the strains was a scarlet or non-scarlet infection, were neutralized by control antitoxic serum produced by a single strain.

A study of the action of streptococcus toxin in different individuals and in different animals, and of its neutralization by different antitoxins, demonstrates that certain phases of tissue susceptibility are essential to the action of that toxin. Since tissue susceptibility is such an important factor, and since it is practically impossible to demonstrate a specific incitant of scarlet fever or other infectious processes attributed to the streptococcus, the necessity for assuming a specific incitant of the disease may be reasonably questioned.

Since the different streptococci vary greatly in their toxic and antigenic action, it is essential to select the most representative strain or strains for the immunization of horses, in order to obtain serums of the highest potency and broadest poly-

valency. The Dick strains I and II which have been used so generally have not proved satisfactory. Of all the strains tested to the present time the Dochez N. Y. 5 is the most representative and effective in the immunization of horses.

The method of immunizing horses either with toxin alone or with culture alone injected subcutaneously into agar has, in our experience, proved to be inadequate. The standards of potency and polyvalency of therapeutic serums for treatment should be advanced. (According to our experience a minimum standard of 400 to 500 units would be a practical one.) It has not been difficult to obtain a potency of 800 units per c.c. The practical value of concentrating serum has not been demonstrated.

Effective agents for the prevention and cure of scarlet fever are now available and their practical value is clearly defined as a result of recent experience. Vaccination by repeated doses of toxin is an effective measure, but the increasing number of injections and dosage required as a result of experience takes time, which is a practical difficulty. The duration of immunity has not yet been established. The prophylactic injection of serum has not received general support—rather the contrary—and as a practical measure has little, if any, advantage over the immediate treatment of cases as they develop, providing the persons exposed are kept under observation, which is an essential procedure in outbreaks, irrespective of preventive inoculation. Preventive measures in scarlet fever thus have an application practically limited to special outbreaks.

The therapeutic action of the serum in the cure of the disease is prompt and effective. The necessity of using it in mild cases has been questioned. In the very toxic, fulminating cases, and late in the disease after serious complications have developed, the action of the serum is not always apparent, or is evanescent, but it does no harm. Evidence is accumulating that some of the cases with complications respond to treatment and that the administration of the serum prevents the development of these complications. Thus it is of the utmost importance that serums of the highest potency and polyvalency be used in the treatment of this disease if definite information is to be gained from statistics.

The disease has become so mild or modified in type in recent years, and varies so greatly in different groups of cases; the mortality is so low and spontaneous recovery so prompt and frequent; the potency of the serums used in the treatment of cases so seldom recorded, and the types of cases selected for treatment are so variable; that it is impossible to compare statistical reports or to draw definite conclusions. There is no question, however, that prompt treatment with an adequate dosage of potent serum is not only effective in curing or shortening the course of the uncomplicated disease, but that it also prevents the development of complications in many cases treated.

This series of cases cannot be considered to have been treated under the most favorable conditions. It includes cases in all districts of the state, urban and rural, and is not limited to those treated in the best hospitals.

Imagination and That "Cooked" Taste in Milk

WHILE in Olean several weeks ago in connection with a "Milk Week" program, a member of the department staff was taken to visit the plant of a young milk dealer. According to the dealer's own statement, at one time he had been an active opponent of pasteurization but early in the course of the serious typhoid fever epidemic which had visited the city he went out on his route one day and discovered that a number of his patrons had gone over to dealers in pasteurized milk. Within twenty-four hours he had decided to take up pasteurization, had ordered equipment and had never had any occasion to regret the change. For a period of about two weeks after he started pasteurizing he was unable to get new bottle caps and continued to deliver his milk with a "raw" milk cap. The day that his milk arrived for the first time bearing a "pasteurized" label he began to get protests from his patrons, who said: "We can't use pasteurized milk; we don't like the taste of it," etc. When he called their attention to the fact that they had been using pasteurized milk for two weeks without knowing it, most of them were converted.

This recalls another episode supporting the statement so frequently made that if milk is properly pasteurized even an expert cannot distinguish it from raw milk by the taste. About two years ago the annual meeting of the Pennsylvania Association of Dairy and Milk Inspectors was held at Harrisburg and at an evening banquet milk was served and each one of the approximately 100 "experts" was asked to drink some of the milk with the understanding that the reason for the request would be explained later. Subsequently ballots were distributed and each one was asked to express an opinion as to whether the milk was raw or pasteurized. After the vote had produced an approximately even division of opinion, it was announced that the milk had been pasteurized at 145 degrees.—*Health News*, N. Y. State Health Dept., Oct. 7, 1929.

Relationship of the Streptococci Causing Erysipelas*

ANNA W. WILLIAMS, M. D., FELLOW A. P. H. A.

Bureau of Laboratories, Health Department, New York, N. Y.

IT is interesting to recall that the first specifically named streptococcus was designated *Streptococcus erysipelatos* (Fehleisen in 1882). Later (1889), Widal and many others following him claimed that this streptococcus was identical with the *Streptococcus pyogenes* described and named by Rosenbach in 1884 for a chain coccus isolated from pyogenic lesion.

This idea of the unity of these strains prevailed until comparatively recent times and even yet, though the more minute serologic tests have added to our knowledge of the diversity and relationships of streptococci, the relationships of the streptococci isolated from erysipelatous lesions are far from being clearly demonstrated.

The chief tests that have been claimed as significant in differentiating these streptococci from other streptococci of the beta type are the absorption of agglutinins, the effect on so-called endotoxins of their antibacterial serums and the neutralization of exotoxins with their antitoxins. All of these tests require highly trained technical workers. Perhaps this is the reason why comparatively little minute and comprehensive work has been done with them and why such varied reports regarding them have been published.

The first work published on agglutinin absorption with an appreciable number of strains from erysipelas was by Birkhaug[1] in 1925. He claimed that out of 34 strains 91 per cent were agglutinated (and absorbed (?)) by "seven immune erysipelas serums" and that "of 45 strains of hemolytic streptococci from sources other than erysipelas, 9, or 20 per cent, were agglutinated by several immune erysipelas serums."

At that time we had begun to gather strains of hemolytic streptococci from erysipelas in connection with our work on scarlet fever, and on our request Birkhaug kindly sent us 11 of his strains. We isolated 19 strains from typical erysipelas cases at Bellevue Hospital,

* Read before the Laboratory Section of the American Public Health Association at the Fifty-eighth Annual Meeting in Minneapolis, Minn., October 1, 1929.

1 from a case following scarlet fever at Willard Parker Hospital, and 1 from a laboratory infection with a strain isolated from a scarlet fever throat.

When Birkhaug sent his strains he said they all belonged to one serologic group by absorption of agglutinins. When we found on testing these strains with carbohydrates immediately after receiving them that they fell into two groups—one of 8 strains into the pyogenes group (Holman's classification), and the other of 3 strains into Holman's subacidus group—we injected two lots of rabbits, each with a strain from one of these groups, in order to obtain an agglutinating serum, choosing C 3 from the pyogenes group and B 3 from the subacidus group. After obtaining a satisfactory serum we found that all but 1 of the pyogenes group from Birkhaug fell into the same agglutination group, and all 3 of the subacidus fell into another agglutination group. We called the first group E Type I and the second group E Type II. Of 21 strains of our own, 7 fell into the E Type I group, 1 into the E Type II group, and 13 into neither. Later we found that 3 among the 13 unclassified cross absorbed with our scarlet Type IV group, and 1 with our scarlet Type I group. We also found that 2 strains out of 29 from meningitis cases in New York City, 1 strain from pneumonia blood, and 1 from pneumonia sputum out of several cases at Harlem Hospital, fell into our E Type I group.

The finding of this definite relationship between certain strains from erysipelas and certain from scarlet fever might have been predicted from the recorded instances of clinical relationship between the two conditions so labeled. That Birkhaug did not find a relationship to scarlet fever strains is explained by the fact that he worked with a comparatively few scarlet fever strains, these possibly falling into our Type Sub I group (our largest scarlet fever group), or into some other group. That the B 3 group—our E Type II—subacidus strains, escaped him is harder to understand, since we have found that this is an extremely clear-cut group. The agglutinated bacteria are always sharply differentiated in the brilliantly clear serum and the absorptions or non-absorptions with the strains are complete—no lowering of the titer unless it is completely lowered; that is, these 4 strains of E Type II stand out as giving no evidence of sub or lateral varieties up to the time of writing. Moreover, these strains rather easily gave good stable suspensions for antigens, while we have had some difficulty in getting usable antigens from most of the other strains from erysipelas.

Another interesting fact we discovered might explain why some non-comparable results have been reported. One of the strains given us by Birkhaug, C 63, the one that had not fallen into any of our

agglutinative groups, we used to obtain another serum, with the object of finding a new agglutinative group among the strains that remained ungrouped. What was our surprise to find that this strain contained only common agglutinogens for all of our type strains from scarlet fever, as well as for E Type I strains. Only E Type II strains did not absorb from it. One strain from scarlet fever—68[2]—that had not fallen into any group, we found to have the same characteristic. The cross absorption test is shown in Table I. Other members of the different groups showed similar reactions.

TABLE I

STRAIN OF HEMOLYTIC STREPTOCOCCI FROM ERYSIPELAS SHOWING ONLY COMMON AGGLUTINOGENS

Absorbed Serum	Absorbing Strains	Serum Strain	Agglutinations							Antigen Control
			100	200	400	800	1,600	3,200	6,400	
C 63		C 63							−	−
C 63	C 63	C 63	−	−	−	−	−	−	−	−
C 63	C 3 (E F)	C 63	−	−	−	−	−	−	−	−
C 63	55[4] (S Sub I)	C 63	−	−	−	−	−	−	−	−
C 63	115 (S I)	C 63	−	−	−	−	−	−	−	−
C 63	114 (S II)	C 63	−	−	−	−	−	−	−	−
C 63	57[3] (S III)	C 63	−	−	−	−	−	−	−	−
C 63	28[1] (S IV)	C 63	−	−	−	−	−	−	−	−
C 63	B[3] (E II)	C 63	+	+	+	+	+	+	−	−
C 63	C[14] (E II)	C 63	+	+	+	+	+	+	−	−
C 63	C[65] (E II)	C 63	+	+	+	+	+	+	−	−
C 63	E 9 (E II)	C 63	+	+	+	+	+	+	−	−
C 63	68	C 63	−	−	−	−	−	−	−	−
C 3	C 63	C 3 (E I)	+	+	+	+	+	±	−	−
B 3	C 63	B 3 (E II)	+	+	+	+	+	+	−	−
55[4]	C 63	55[4] (S Sub I)	+	+	+	+	±	−	−	−
115	C 63	115 (S I)	+	+	+	+	±	−	−	−
114	C 63	114 (S II)	+	+	+	+	±	−	−	−
57[3]	C 63	57[3] (S III)	+	+	+	+	+	−	−	−
28[1]	C 63	28[1] (S IV)	+	+	+	+	+	±	−	−
68[2]	C 63	68[2]	−	−	−	−	−	−	−	−

Thus we have 2 strains that are of low grade in agglutinogens. Whether they were "degraded" in the stock cultures or whether they were colony degradents from the time of isolation we cannot say. We had only the 1 strain from Birkhaug, and while from our own 68[2] scarlet fever we fished 2 colonies, the other 1 had been discarded long before. Andrews[5] states he found that about 50 per cent of his colony strains from certain cultures of the salmonella group stimulated only group agglutinins. Krumwiede and Cooper[6] in investigating this observation found that they sometimes could get only 1 in 100 colonies that showed this phenomenon. If such a strain as C 63 had been the first to be chosen by any worker, and cross absorptions had not been done,

he would have found a large group of "related" hemolytic streptococci by "agglutinin absorption."

We see then that we have found 1 comparatively large agglutination group among the erysipelas strains, 1 small one and several strains related to our scarlet fever strains, while there still remains quite a large group not belonging to any of the above, as yet unclassified by absorption of agglutinins. Moreover, we found several strains from sources other than erysipelas falling into E Type I group. We realize that this is a comparatively small number of strains. In a larger series, or in a series obtained in other parts of the world, we would no doubt get a different percentage in the groups, and find other groups.

Our percentage of strains falling into Birkhaug's big group is decidedly smaller than his—46.9 against his 91.2 per cent. In our second group there are 12.5 per cent of strains. Then we have 9.4 per cent in our scarlet fever groups, and our unclassified strains make up 31.2 per cent. We have so far found 4 strains out of about 100 tested from sources other than erysipelas that fall into our E Type I group, while 3 scarlet fever strains cross absorb with 3 erysipelas strains. This makes about 7 per cent of strains from sources other than erysipelas that are related to erysipelas by agglutinin absorption against Birkhaug's 20 per cent.

THE PROTECTIVE ANTIBODIES AGAINST THE WHOLE ORGANISMS ("ANTIENDOTOXINS")

We have found that on the whole these antibodies run with the agglutinins in specificity, that is, we have found no marked cross protection between the groups, and no cross protection with scarlet fever strains and other strains that do not fall into the groups.

For this reason and because the chief lesion in erysipelas is probably due to the endotoxins, we should have these antibodies in our serums as well as, and perhaps more than, the antitoxins.

EXOTOXIN PRODUCTION

All of the strains chosen as type strains of the different groups, and many of the individuals in the groups, as well as many other strains tested, have each produced exotoxin in variable degrees. Several have produced an exotoxin as strong as did most of our scarlet fever strains, but the majority do not.

We have tested the toxins of EC 3 and EB 3 on a large series of children between the ages of 3 and 10 years in comparison with our standard toxin with the results shown in Table II.

Birkhaug claims that the toxin of his erysipelas strains gives a

significant skin reaction in people susceptible to erysipelas and in those just coming down with the disease. But we have found no definite evidence of this. On a series of patients tested soon after they entered the hospital with 2 skin-test doses (as far as we were able to determine) each of 3 toxins—one our scarlet fever standard toxin, and the other two—EC 3 and EB 3—from erysipelas, we obtained irregular results which are given in Table III.

Of course, the question of determining the correct skin-test doses is a difficult one. The effect of serum given the same day, or 24 hours before the skin test, was in this series of cases not apparent. If the chief lesion in erysipelas is due to the "endotoxins" we would not necessarily expect a markedly regular skin-test dose.

It is easy to obtain a strong antitoxin against an exotoxin of any strain, but to show the specificity of this antitoxin in human beings is another matter. It is a question primarily of the complexity of the toxins and of the dosage. We have recently[4] called attention to this complexity first clearly brought out by Park[5] in 1925.

We have tested several erysipelas toxins besides B 3 and C 3, each on a small series of children, against our scarlet fever serums and against scarlet fever convalescent serum. We have also tested our scarlet fever toxins against erysipelas antitoxin, and found cross neutralization in the majority of children tested. For this reason as far as the exotoxic activity of these strains is concerned we infer that an antitoxin stimulated by the exotoxin of any strain, be it from scarlet fever, meningitis, erysipelas or any other disease process, would, if strong enough, protect against further injury by the exotoxins of most strains in most people.

The clear-cut analysis by McCann[6] of alternate cases of erysipelas treated with erysipelas antitoxin and scarlet fever antitoxin gives evi-

23 of the 82 cases had no serum.

dence in favor of the hypothesis that antitoxic serum alone is not sufficient to give significant results in curing erysipelas.

Unfortunately we have as yet had no practical application of the comparative worth of antitoxic against antibacterial serum. Symmers's cases[7] were treated with a serum having presumably both antitoxic and antibacterial antibodies, but we do not know the absolute or relative strength of those antibodies since no tests of their titer were reported. Neither were they reported for Birkhaug's serum.

Since none of the three serologic tests described—the agglutination test, the protection test against endotoxins, and the exotoxin neutralization test—shows one definite erysipelas group, the name *Streptococcus erysipelatos* seems to be without specific significance, and might be dropped with the name *Streptococcus scarlatinae* as a species name, for the present at least, in favor of the name *Streptococcus hemolyticus* with the designation of the agglutinative type following it.

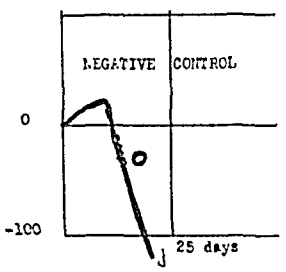
An Improvement in the Quantitative Assay of the Antiscurvy Vitamin (C)*

WALTER H. EDDY, PH. D.

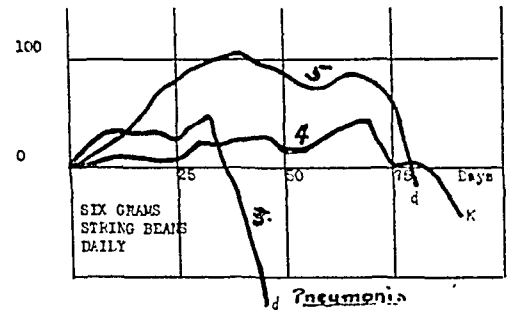


Department of Physiological Chemistry, Teachers College, Columbia University, New York, N. Y.

WHILE the experimental data presented in this paper have to do with a review of present methods of evaluating antiscorbutics and the claims of Höjer's methods as contrasted with the Sherman method (now generally in use in the United States), the subject has a very direct bearing on health problems and practices, for the method of Höjer assumes a very specific response of teeth to presence or absence of vitamin C. That this response is specific and supports the suggestions for dental nutrition practice, first emphasized by Dr. Percy Howe and more recently by Hanke and Wells, will appear as we outline our experimental findings obtained in parallel studies of vitamin C assay methods.

The Sherman method[1] was first presented in 1922. LaMer, working with Sherman and Campbell, developed a diet for guinea pigs which was markedly superior to the hay-oats-water diet, up to that time generally used to produce experimental scurvy in these animals. Its superiority was based on evidence, considered satisfactory at the time, that it contained all the nutritional factors necessary for normal growth except vitamin C. Guinea pigs of 300 gm. on this diet developed acute scurvy and died of that disease in from 25 to 30 days. The smallest amount of addendum necessary completely to prevent scurvy for a period of 90 days when added to this diet in daily doses, was called the minimum protective dose, and since that dose was inevitably expressible only in amount of food carrying the same, Sherman's unit quantity of antiscorbutic, like that of Holst, was defined as the smallest quantity of food source necessary to total absence of scurvy symptoms in a 90-day test using guinea pigs and the above basal diet.

Since 1923, Kohman and I have used the Sherman method[2] in studying a wide range of fresh and canned vegetables and fruits.



* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

FIGURE I—A TYPICAL SHERMAN-LAMER TEST. Weight curves are shown of guinea pigs on various intakes of canned string beans and also the autopsy scores of each of the pigs on these diets. By this method we obtained complete protection from scurvy symptoms on a dosage of 18 gm. of canned string beans daily. In this series we used the basal diet given.

Statistically our numbers of test animal records now run into the thousands and provide material for some comparative observations of interest and profit. During the past year, therefore, my laboratory has devoted considerable time to such critical review of existing data and, through the coöperation of Dr. Gilbert Dalldorf of the Department of Pathology of the New York Hospital, we have extended our review by new experiments aimed to evaluate criticism of the Sherman method and of some of the substitutes offered, notably that of Höjer.[8]

IS THE ORIGINAL SHERMAN-LAMER BASAL DIET COMPLETE IN ALL GROWTH FACTORS EXCEPT VITAMIN C?

Their basal diet as given in 1922 consisted of the following:

	Per cent
Ground whole oats	59
Baked skim milk powder	30
Butterfat	10
Salt (NaCl)	1

We are using today the following modification of this diet:

	Per cent
Baked skim milk	30
Butterfat	9
Salt	1
Rolled oats and wheat bran (½ & ½)	59
Cod liver oil	1

plus a certain amount of yeast fed separately.

The bran was added to supply roughage in greater quantity, the cod liver oil as insurance against vitamin D deficiency, and in certain cases we had direct evidence of lack of one or more of the vitamin B factors, making yeast of value in supplementing the oats and milk content of these factors.

Sherman introduced a scurvy symptom score based on autopsy findings. Figure I shows the nature of this score and its use in determining minimal protective dosage of a tested antiscorbutic.

In spite of score and correction of basal diet defects the test has been criticised. The experimental pathologists took a hand in the matter. In his treatise on "Scurvy," Hess has adequately summarized the pathology of the disease up to the date of publication (1920). So far as I can find, Jackson and Moore,[4] 1916, were the first to note scorbutic changes in teeth. These observations were confirmed by Zilva[5] in 1919, but greatly extended by Höjer[3] in 1924. Aschoff and Koch[6] in 1919 also turned their attention to the pathology of scurvy,

and it is their viewpoint as to the function of vitamin C that led to the theory advanced by Wolbach and Howe[7] in 1926. We will return shortly to this work of Wolbach and Howe and their theory. From the viewpoint of methodology in assay, the work of Höjer especially concerns us. This Swedish pathologist supplemented his first studies, published in 1924, by a scheme for utilizing tooth pathology as a quantitative measure of antiscorbutic value. His scheme was published in detail in 1926.[8] It was critically reviewed by Goettsch and Key[9] in 1928. The following quotations from the 1926 paper of Höjer explain briefly why this scheme constitutes both a challenge of the Sherman method and a claim for efficiency requiring study:

> Sherman and others, in 1922, therefore proposed to limit the experimental time to 70 or 90 days and then to make a macroscopic post-mortem examination to make sure that there were no internal hemorrhages or other signs of scurvy. Sherman also introduced the rating of the scorbutic signs in animals which were not fully protected, and thus he estimated the dose of antiscorbutic given in quarters of the fully protective dose. Even with these improvements of Sherman's this method of determining the fully protective dose is very inaccurate, and often gives variations of 100 per cent or more.
>
> . . .
>
> Naturally a biological method cannot afford the accuracy or the simpleness of a chemical one. It is indeed the lack of a chemical method for the determination of the antiscorbutic value that has called in experimental pathology as a temporary aid to the physiologist. As a biological method, and in comparison with that hitherto used, my method has the following advantages: First, it is accurate in fixing the fully protective dose. This is of value particularly in physiological work. Secondly, the method requires only 3 weeks instead of 3 months. This is an essential factor in hygienic work. Lastly, being shorter, it is more economical than the older methods.

What is this method? In brief it rests on the claim that the teeth show specifically in 3 weeks or less the absence of an adequate amount of vitamin C in the diet. Höjer's own description[8] of his technic follows:

> As previously, young guinea pigs from a certain day on are given a basal diet free from antiscorbutic, but otherwise complete, and to this diet are added quantitatively daily doses of the juice to be examined. For a sharp determination of the fully protective dose it is advisable to have several animals on different doses. In addition there ought to be two control animals on the basal diet alone, and two on the basal diet with a fully protective dose of a known antiscorbutic. After a period of 10–14 days all the animals are killed. The one-half of the lower jaw is taken out and decalcified in a 5 per cent tri-chloracetic acid solution. It is then embedded and sectioned after 1 week. The section is made through the foremost molar at right angles to the longitudinal axis of the jaw. Some sections are stained with hematoxylin-eosin, and others with tri-oxyhematin according to the method of Hansen.

Such sections according to Höjer not only reveal histological pictures characteristic of scurvy or its absence, but it is possible from pictures of partially protected animals to predict the fully protective dose, as shown in Table I.

TABLE I

DETERMINATION OF THE ANTISCORBUTIC VALUE OF FOOD BY HÖJER'S METHOD[8]

	Part of Protective Dose
1. Dentine of normal size; its inner and outer layer uniformly colored; predentine regular, uncalcified; dentine and predentine holding collagen—	
a. Odontoblasts long, slender, parallel, of equal height	1.0
b. Odontoblasts partly shorter	0.9
2. Dentine very thin, uniformly colored; odontoblasts parallel, short	0.8–0.3
(The degree of osteoporosis, hyperemia and collagen permits the distinguishing of different stages, but not very sharply. Those animals whose dentine formation seems to have been arrested are therefore excluded.)	
3. Dentine in inner and outer layer differently colored.	
a. Odontoblasts on the larger pole of the incisor cross-section short and parallel	0.8–0.3
(1) The Tomes' canals going parallel through a normal predentine	0.8
(2) The uncalcified predentine defective formation of network bone beginning	0.7
(3) Uncalcified predentine lacking	0.7–0.5
(4) Network bone formation greater	0.4
(5) Tomes' canals in the old dentine widened	0.3
b. Odontoblasts on the larger pole of the incisor cross-section no longer in continuous layer	(0.3–) 0.2–0.0
(1) Tomes' canals in the outer layer of new bone	0.2
(2) No Tomes' canals in the new bone, osteoporosis and hyperemia well developed	0.1
(3) The old odontoblasts in greatest disorder, osteoporosis and hyperemia very evident	0.0

A tooth section showing the picture 3, a, (1), with 0.5 gm. of antiscorbutic daily would permit prediction that the fully protective dose of that antiscorbutic would be 0.622 gm. (0.5 gm. $=$ 0.8x).

The value of Höjer's method obviously depends upon substantiation of claims for specificity. Do the tooth changes he reports result solely from the absence or inadequacy of vitamin C in the diet? Are they affected in any measure by absence or presence of vitamin D? Can we rely on the pictures of partial protection he presents to predict full protective doses?

To date two critical studies support his claim that tooth changes picture specific and early response to absence or inadequacy of vitamin C.

Goettsch and Key[9] have reported comparisons of Höjer's method with the older type. They studied particularly the question of whether the tooth changes noted had any correlation with symptoms of rickets and found none. The actual tooth changes were as de-

TABLE II

TABLE AFTER GOETTSCH AND KEY[9]

No. Guinea Pigs	Line Test	Blood serum mg. Ca per 100 c.c.	Mg. P per 100 c.c.	Per cent ash of dried and extr. femurs	Diagnosis
18	No rickets	9.9	5.8	59.4	Death by scurvy
24	"	11.3	5.3	55.0	"
28	"	12.0	5.3	57.9	"
35	"	9.4	5.0	56.2	Partly protected by 0.5 c.c. orange juice
36	"	10.1	5.0	57.4	Partly protected by 0.5 c.c. orange juice
38	"	10.9	5.0	59.0	Partly protected by 0.5 c.c. orange juice
31	"	9.8	5.0	54.2	Completely protected by 3 c.c. orange juice
32	"	9.1	5.0	56.2	Completely protected by 3 c.c. orange juice
34	"	9.0	4.5	56.2	Completely protected by 3 c.c. orange juice

scribed by Höjer and in their hands confirmed his criticism of the Sherman method, for whereas the Sherman method fixed 1.5 c.c. as the protective dose for orange juice, prevention of the scorbutic symptoms in teeth required a daily dosage of 3 c.c. of orange juice. Their only stricture is the reliability of prediction from the results with partially protected animals and they feel that individual variation in animals calls for fairly large numbers on these intermediate tests if the predictions as to full dosage are to be relied upon.

Wolbach and Howe[7] gave more attention to Höjer's histology and his theory of its cause than to his use of the study of antiscorbutic testing. They say:

> We do not question the accuracy of Höjer's description. His findings are different in important respects from ours, as we found in the state of complete scorbutus no formation of " osteodentin " or pulp bone. We believe that his diets were not completely deficient, because we obtained both conditions answering to his descriptions only in guinea pigs fed alternately on deficient and normal foods. . . . Our results corroborate completely and extend the deductions of Aschoff and Koch, so that we characterize the scorbutic state as one due to the inability of cells of supporting tissues to produce intercellular substances and to maintain existing intercellular substances.

Later in their paper[7] they further hold that Höjer's theory to account for changes as due to degeneration or the change of odontoblasts to osteoblasts is not proved. Rather they consider that the odontoblasts do continue to function, but through lack of a substance supplied by vitamin C their proliferated " jell " fails to set into dentine.

> . . . We therefore advance the theory that the failure of cells to produce intercellular substance in scorbutics is due to absence of an agent common to all supporting tissues which is responsible for the setting or jelling of a liquid product.

The immediate purpose of the present paper is to make clear the possibilities offered by the Höjer test for rapid assays of antiscorbutic values and to present evidence from our own studies of its validity. To that end we have devoted considerable time during the past year to checks and comparisons with our previous assays and also some study of material hitherto unpublished. We report here three such specific comparisons.

I. CANNED STRING BEANS TESTED BY BOTH METHODS

In Figure I is presented a series of studies of canned string beans by the Sherman method. Using both growth curves and scoring system this study showed 18 gm. of canned string beans per day to be the minimum protective dose. This series was then repeated using the Höjer procedure in part. Figure II represents tooth sections obtained in this study.

Photograph A of Figure II shows a magnified tooth section from an animal receiving 18 gm. string beans daily at the end of 30 days on the diet. (This was the protective dose by the Sherman method.) Even in this period the beginnings of scurvy are evident, though slight. The odontoblasts are irregular and beginning to separate from the dentine. A layer of jelly is beginning to form. Photograph B shows a much more distinct disturbance in tooth structure. The period on diet is the same (30 days), but the dosage of antiscorbutic was only one-third as much (6 gm. string beans daily). True dentine is markedly reduced. The odontoblasts are very irregular and have formed much false dentine. This material was partly bone-like, tending to support Höjer's claim that the character of the odontoblast output is actually changed in quality.

Photograph C is given to show the odontoblasts in higher magnification, and photograph D shows that the effect of inadequate antiscorbutic was already manifest in 20 days on the diet. With this method we were unable to reach a dosage of string beans that completely protected teeth. Even 18 gm. per day had already become difficult to use without reduction of the basal intake below efficiency in other factors.

The series shows clearly, however, that if the tooth is a true index of antiscorbutics, it is a much more sensitive one than the Sherman scoring system; that tooth protection demands more antiscorbutic than does the prevention of external symptoms of scurvy. This particular study definitely confirmed the claims of Höjer and others that the guinea pig's tooth responds very promptly to variation in vitamin C.

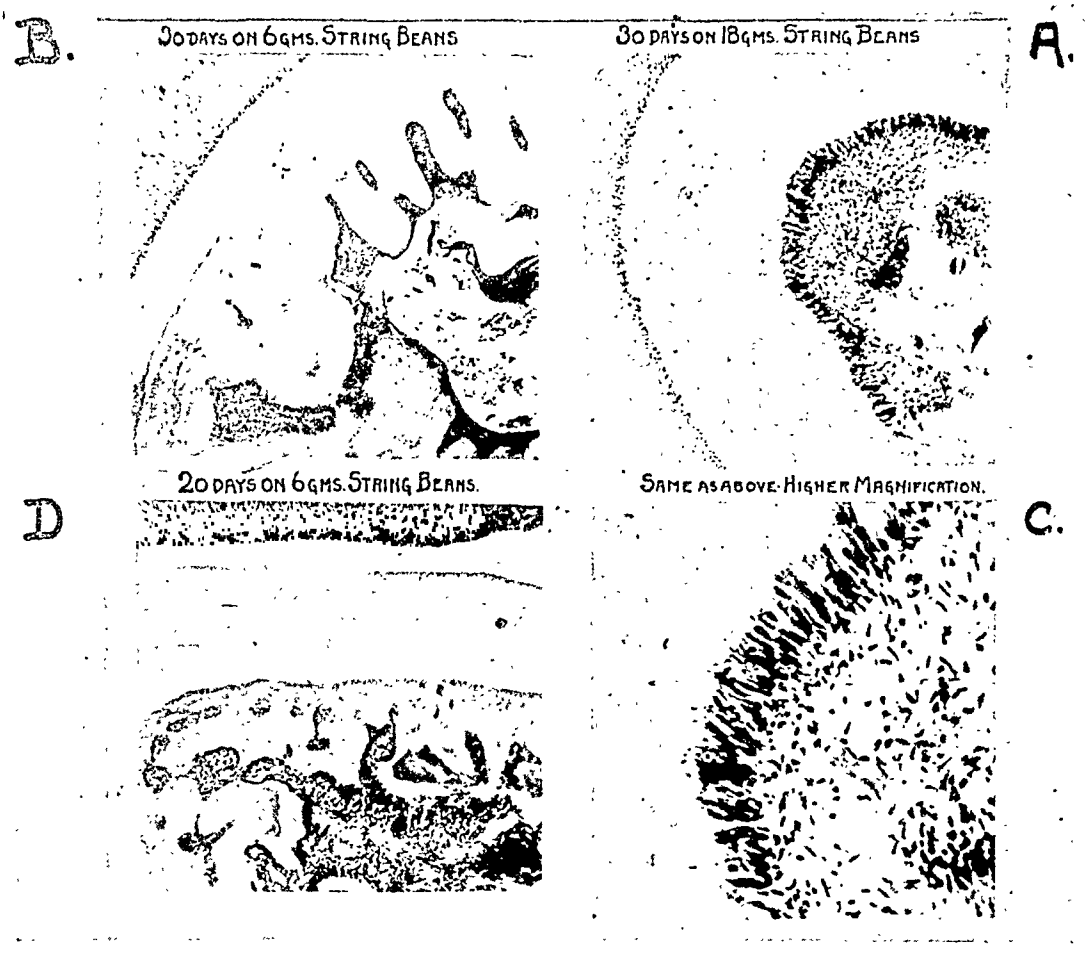

FIGURE II—TYPICAL HÖJER TEST RESULTS

In this series tooth sections were made at the end of 20 and 30 days on basal diet plus different intakes of canned string beans. Photographs A, B, C, and D are microphotographs of tooth sections from typical animals.

Photograph A—This shows the tooth of a guinea pig that had received for 30 days a daily dosage of 18 gm. canned string beans. The tooth shows slight scurvy. The broad band of dentine is separated from the cells which form it (odontoblasts) by a narrow band of jell-like material.

Protograph C—This shows a region of the section given in A highly magnified to show the soldier-like row of odontoblasts, the dentine with its fine striations of Tomes canals and the beginnings of the separation layer between odontoblasts and dentine.

Photograph B—In contrast to the above note in this section the very narrow band of dentine, the complete confusion of arrangement of the odontoblasts, the soldier-like rows are gone and the cells are in irregular islands in the pulp cavity. Between islands and dentine is a mass of semi-solid jell quite unlike true dentine. This effect was produced by inadequate antiscorbutic, 6 gm. canned string beans instead of 18 gm. daily.

Photograph D—Note that even in 20 days the effect of inadequate antiscorbutic is plainly evident.

II. ORANGE JUICE SERIES

During the past year we were asked to compare the antiscorbutic value of California and Florida oranges. Picking by size in the open market we carried out the regular Sherman test. Both types proved by this method fully protective in daily doses of 1.5 c.c., neither showing any appreciable superiority as an antiscorbutic over the other. This series, however, also permitted us at the same time to check Goettsch's[9] criticism of Höjer's method as well as to compare again Höjer's method with Sherman's in our laboratory. The check with Goettsch was remarkably good. In our hands 3 c.c. of either California or Florida orange juice was necessary to prevent tooth changes characteristic of scorbutus, exactly the relation obtained by Goettsch in her comparison (see Figure III, photographs A and B).

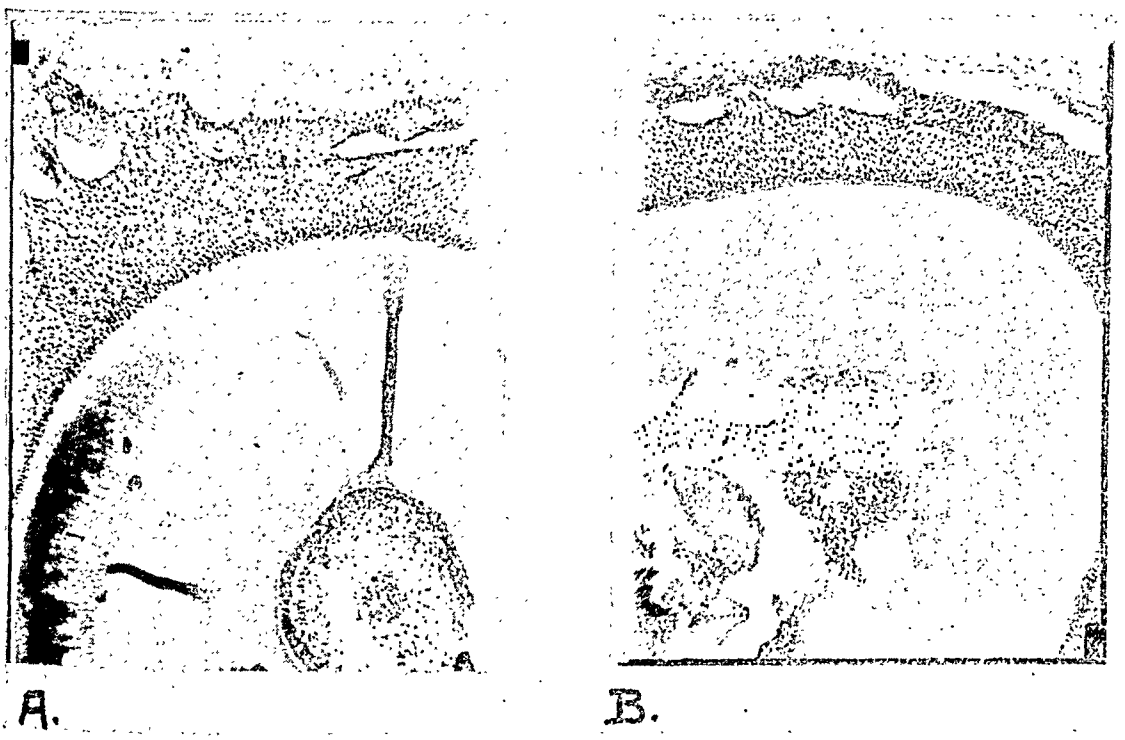

FIGURE III—THE EFFECT OF ORANGE JUICE ON TOOTH FORMATION

Photograph A—Tooth section from guinea pig on 3 c.c. of orange juice daily for 20 days. Note normal thick dentine, perfectly regular row of odontoblasts in direct contact with lower edge of dentine.

Photograph B—Tooth section from guinea pig on only 2.5 c.c. of orange juice daily for 20 days. Note that 0.5 c.c. difference is plainly shown in disturbance of tooth structure. Odontoblasts have become irregular and begun to separate from dentine.

The tooth therefore is quickly responsive to very slight differences in antiscorbutic dosage.

III. BANANA ANTISCORBUTIC VALUE BY HÖJER METHOD

In 1926[10] I reported to this Association a study of the antiscorbutic value of the banana. Five gm. daily was the minimum protective dose determined by the Sherman method at that time. We have now retested the banana by the Höjer method. In doing it we introduced a modification suggested by Dr. Wolbach, that is, to include as positive controls in each series one animal fed for 5 days on a recognized adequacy of antiscorbutic following his 16 days on the banana intake. This procedure enables one to judge with more exactitude as to when the fully protective intake is reached. Figures IV and V show the tooth results.

Exactly as in the case of orange juice, the antiscorbutic dose of banana for tooth protection was found to be double that previously obtained as minimum protective dose by the Sherman method, 10 gm. instead of 5 gm. It seems hardly possible that this ratio is entirely fortuitous. If further tests establish it as the true difference between tooth and general body requirements it will be a simple matter to convert antiscorbutic values that have been reported since the general adoption in this country of the Sherman method into tooth protective values. We will need only to multiply by two.

What the true values are in terms of teeth obviously requires much more extended study. I believe, however, that the results reported herewith justify considerable faith in the Höjer method, and its speed, its relative simplicity, its greater freedom from the danger of contaminating disease factors in the longer test all commend it to our careful appraisal.

The facts on which the Höjer method rest have a wider significance in public health procedure. Scurvy, in fact, is still a relatively rare hospital disease when diagnosed by the usual signs. *If tooth health is so directly related to vitamin C content of diet as these studies imply,* we must not only give more antiscorbutic, but greater quantities for tooth health alone. Hanke[11] reported at the recent International Physiological Congress in Boston studies that confirm this view: He studied 100 cases, afflicted with every type of dental disorder, in subjects ranging from 4 to 60 years of age. He found the diets not markedly lacking in vitamin D, but *40 per cent were markedly deficient in vitamin C.* He says:

> It is possible, by means of a diet containing an abundance of vitamin C, to produce solid gum tissue, to arrest caries and, with the aid of prophylactic measures, to cure pyorrhea and induce bone regeneration in the alveolar tissue.

This view of Hanke's has been urged with much emphasis by Dr. Percy Howe.

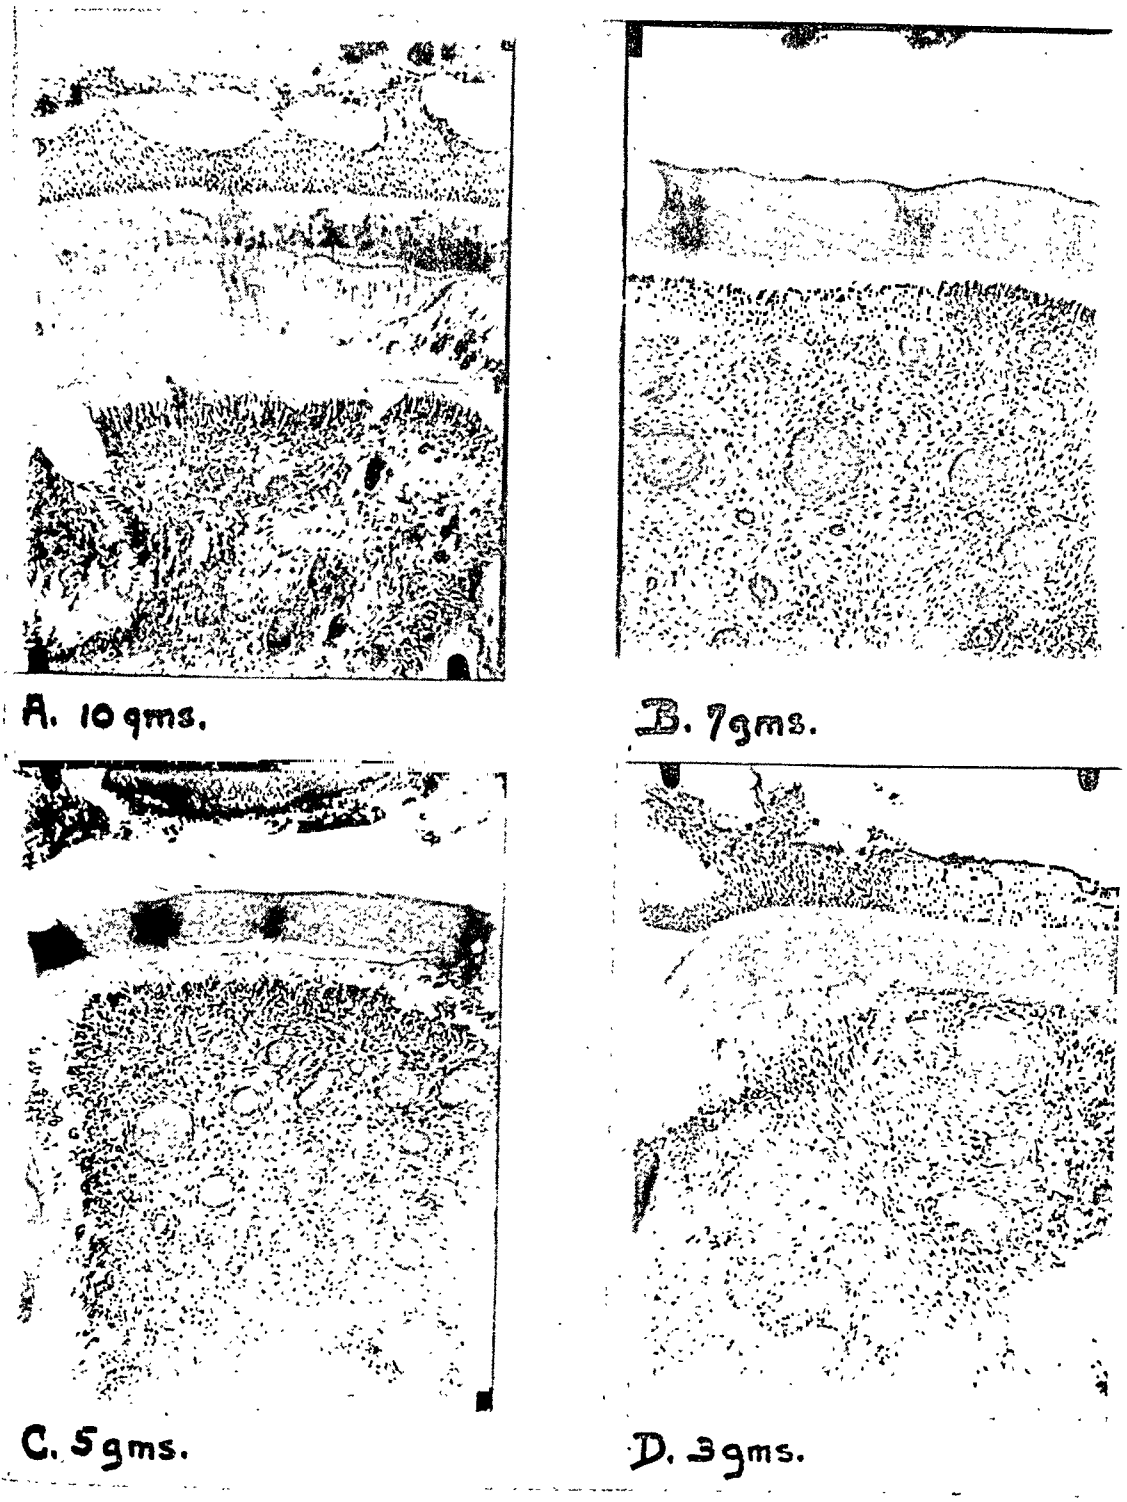

FIGURE IV—THE BANANA AS AN ANTISCORBUTIC

A—Ten gm. banana daily completely protective to teeth.

B—Seven gm. banana daily insufficient. Reduced dentine, odontoblasts still in regular rows but separated from dentine.

C—Five gm. banana daily gave still less dentine and beginning of irregularity in odontoblasts. This is the minimum protective dose by Sherman Method.

D—Three gm. banana daily shows complete derangement of odontoblasts.

As in the case of orange juice tooth protection requires double the amount of anti-scorbutic per day as was shown adequate against general scurvy symptoms by Sherman test and score.

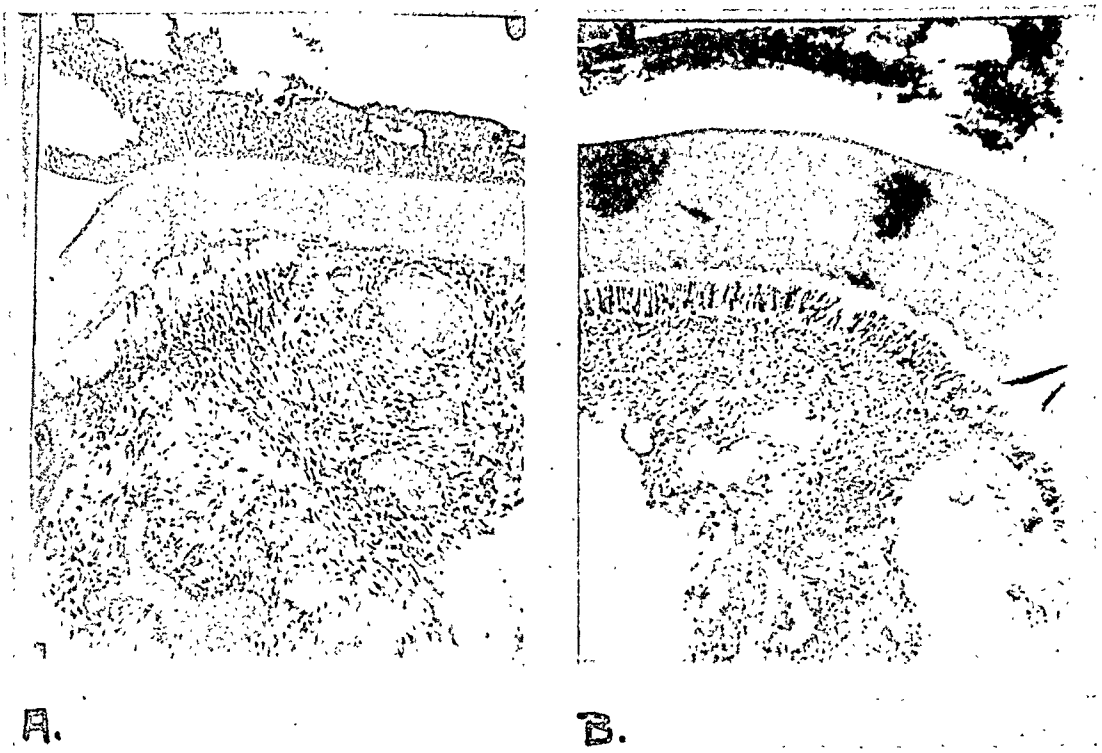

FIGURE V—SHOWS SPEED OF SCURVY CURE WHEN ANTISCORBUTIC IS ADEQUATE

A—Section of tooth of guinea pig on only 3 gm. of banana per day at the end of 21 days.

B—Section of tooth of another test animal who was fed 3 gm. banana daily up to the 18th day and then placed on a diet with completely adequate dosage of antiscorbutic for 5 days more.

Note contrasts. Five days had restored regularity to odontoblasts and brought about formation of a considerable amount of new dentine. See line of separation between new and old dentine.

With all the attention that vitamin D is receiving as a bone-former today, and by inference as affecting tooth formation, it is at least significant to find that the major tooth forming factor is quite a different vitamin, and of value to recognize this fact in applying dietary measures to tooth health.

Training Teachers in Health Education*

ELMA ROOD, R. N.

Professor of Nursing Education, George Peabody College for Teachers, Nashville, Tenn.

THERE is increasing recognition, on the part of workers in child health, of the tremendous influence which the classroom teacher has in encouraging good health habits, influencing the child's attitudes and desires, contributing to his ability to coöperate intelligently, and stimulating a real enjoyment in the building and maintaining of a fine, strong body. The more progressive schools are now initiating their own health programs, and are calling on specialists for assistance according to the needs of the children. This places the teacher in the strategic position of determining to a large extent what these needs are. It is therefore evident that the results obtained in any school health program will largely be determined by the teacher's education in health. The most crucial point in which to give this instruction is in the plastic stage of the first years of teacher training.

Teachers' colleges and normal schools are vocational, presumably preparing young people to administer education, to build citizens. Among their responsibilities in realizing the objectives of education, the health of children takes a prominent place.

The problems which confront the person who is preparing these young teachers to assume this responsibility are three: first, the basic training and experience given on the college campus; second, the observation and practice afforded in the demonstration school as the testing ground of all theory previously taught; third, the field itself in which the student finally proves the value of instruction received. The problems of teacher training in health will be discussed from these three standpoints.

The conditions surrounding life on the campus loom very large in any consideration of education of a student in health. What he is experiencing daily is being written into his consciousness in vivid terms in comparison with the impression made in many class periods. Much of his experience is definitely connected with his environment,

* Read at a joint session of the American Child Health Association and the Child Hygiene and Public Health Education Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

which, beside being a silent force in education, should also be a reservoir of opportunities for teaching health actively. The public health supervision of the campus should exemplify the very best practice of scientific principles, and should be several leaps ahead of many fields in which the student will work in the future. In other words, it should set the pace in the development of healthful programs for pure water, food supervision, garbage disposal, good ventilation, sanitary cleaning methods, and communicable disease control.

The college campus in reality represents the problems of a small community, where the students are learning positive principles of public health administration which will later be translated into the practices of their communities. A teachers' college in which this vast field of learning is used to its fullest, should be able to pass creditably a survey of fountains, lavatories, water and milk supply, cafeteria, garbage disposal, dormitories, infirmary, and general conditions of cleanliness on all parts of the campus and in all buildings.

The environmental conditions, beside furnishing valuable teaching material, directly influence the personal hygiene and health of the student body, and, as such, should be a matter of close concern of the health department of the college. It is through this department that students are initiated into the health examination, learn their own physical rating, and receive instructions as to defects, habits, and attitudes related to study, recreational activities, diet, and other important points in daily life. The way in which students are able to carry out these instructions often depends upon the environmental conditions, which may either help or hinder efforts to attain a fine standard of health, physical and mental. The college infirmary, while serving as an emergency measure, should also be an educational opportunity for students who for some reason have failed in maintaining health.

Every student should receive in his college course the essentials of personal, school, and community hygiene. The emphasis in personal hygiene should be mainly on promotion of health, with enough physiology to give a background. Credit should be given for the success which the student attains in reaching and maintaining a high degree of health. Principles developed in personal hygiene should be constantly applied, not only to the life of the adult student, but also to that of children. In school and community hygiene courses, there should be constant applications to school environment and practices. These classes should frequently visit the demonstration school to observe problems of water and milk source, food service, seating, lighting, heating, ventilating and cleaning, and should study the way in which they are met.

Beside these courses which are *directly* related to the health education of the student, biology and allied sciences, psychology, home economics, agriculture, physical education, elementary education, and school supervision and administration make important contributions to the understanding of factors which influence the physical, mental, or emotional health of children. Instructors of these courses should share the responsibility of seeing that health principles taught in their classes are actually functioning in the demonstration school.

The content of these courses should also be influenced by problems of the field to which the students will go. State and local boards of health have first-hand information of outstanding community health problems, and are eager to pass on this information to instructors in teachers' colleges. A close relationship should exist between these official agencies and the college staff. Points on which schools are having difficulty as shown by reports from the field should be brought before classes for discussion and tentative solution. For instance, a practical problem in an adjacent community may be that of scarcity of milk and fresh vegetables. Time should be given in food courses to a consideration of basic causes for such conditions. Undernourishment of children, as a common field problem, might well receive attention in courses in nutrition. Responsibility for swimming pool sanitation on the college campus and in the demonstration school, offers a practical project for science classes. In communities in which hookworm, typhoid, and tuberculosis are outstanding problems, time should be devoted to these subjects in science and agriculture.

Even though instructors in all subjects seek to bring out the important health correlations, there is still very great need for a course which shall gather together all the contributions, and show the student clearly, first, how they are significant to the health of children, and second, how they may be applied. This course should be developed in close contact with problems of the demonstration school, and those of the field to which the student will be going. Methods should be developed to fit difficult conditions, such as the rural school with few facilities, for such methods may be adapted to surroundings which are more favorable.

Students should, in this correlation and methods class, develop initiative and originality in planning and carrying out health games, dramatics, field trips with follow-up, group projects, use of current events and newspaper articles, preparation of scrap books, study of some life situations, survey of existing material for health correlations, bulletin boards, silent reading lessons, debates, discussions, demonstrations, and the use of the auditorium period for presenting

any of these. Health examinations and inspections, playground equipment, the hand-washing, and hot lunch service of the demonstration school should be observed and discussed preparatory to later participation.

Definite work should be done in correlation with the various school subjects, such as those of science, social studies, physical education, home economics, and kindergarten and primary activities, so that the students will realize the broad way in which health as a quality of living is tied up with a multitude of life situations. In other words, students should clearly see health, not as a subject bounded by arithmetic on the one hand and geography on the other, but as a condition to be reckoned with 24 hours out of the day, and which constantly presents untold opportunities for influencing the lives of children. If all young teachers could go out with this conception and a genuine enthusiasm to meet the conditions which arise, the problem of child health in our schools would be well on the way to solution.

The second aspect of teacher training for health education is found in the demonstration school, which should be a testing ground of theories taught on the campus. Upon the functioning of health in each classroom depends the impression which the student receives of the practical application of these theories. The demonstration school represents again a small community in which all the principles of public health are carried on with and by the children as far as possible, illustrating the methods of meeting such child health problems as are found in the field. Throughout, the spirit toward health as represented by the principal and teaching staff, and which brings about a real health demonstration, has an immeasurable influence upon the entire student body.

Every student participating in classroom teaching should take part in solving health problems which arise in that room. Each should study children, under the supervision of the teacher, who will utilize the service of special workers in the school. This study should include, among all other phases of the child's development, his physical basis, with as much family background and past history as possible. Such a study enables the student to individualize the child's needs in terms of physical changes, habits, and attitudes, and to make the health program a vital thing to each child.

The demonstration school should be able to measure achievements of the children in every classroom in terms of some accepted standard in health. Every room should be able to show definitely what is being done to meet its problems; how far it has gone in improving

physical conditions, in building definite health habits, in influencing attitudes and desires, in increasing the child's intelligence, and in directing and interpreting his experiences.

In comparison with theory, the demonstration school leaves a vivid impression upon the student teacher. While it is placed second in our chronological consideration of aspects of the teacher training program, it should rightfully be placed first in importance. The success of the health program in the demonstration school will determine very largely the success of the health programs of hundreds of schools in the field. The demonstration school is the keynote in teacher training for health and should represent the culmination of effort on the part of the entire college and of the health agencies in the field in influencing teachers who assume the responsibility for the health of thousands of children.

The third aspect in the development of teacher training in health is found in the field, which is the final test of the student's ability to carry out what has been learned. Every teachers' college sends hundreds of young people out into most difficult territories where there are no organized health agencies and where no immediate assistance is to be had in the solution of health problems.

To help meet this challenging situation, a plan has been tried, in at least two states, of offering these teachers an opportunity to carry out an organized health project in the field, under the supervision of the health education department of the college and on the basis of college credit. In localities where this work has been carried on, interest has been developed which has extended into other schools in that community and which in many cases has carried over in succeeding years without credit.

Up to the present, conferences in the development of the projects have been carried on at intervals at the college. As the field work grows, however, it would seem that supervision should be provided in the field, the supervisor representing to the teacher an immediate helper, consultant and adviser. This supervisor should help the teachers tie up their work closely with local health agencies, and should also help to unify the work of all contributors in the interest of the children's health. Ideally, this supervisor should serve jointly the college and the state departments of health and education.

The field reports of the supervisor should bring into the state and college departments valuable data which should guide them in future efforts. A state health standard is of great value in establishing definite objectives to guide these projects. Every worthwhile project should show some results which contribute to the attainment of this

standard. In reality, every time a teacher launches a project in the field, she becomes an active assistant in carrying on the work of the state departments in health and education. Considering the great number of teachers in the field who have direct contact with children, the total results of this type of state-wide supervision can hardly be estimated. With the possible development of the health work on a state-wide basis, it would seem that a wise provision would be to have a health coördinator who would tie up effectively the work of all departments of the college, of the demonstration school, and of the field.

Whatever may be worked out as the possible solution of this problem, there should be evident a strong development which is definitely moving through the basic sciences and health courses in the teacher training schools, on through the demonstration schools as the preliminary testing ground, out into the field where the supreme test of its value is made, and back into the teachers' college for critical analysis, reëvaluation, and re-adaptation, thus contributing rich source material for the further development of the possibilities of teacher training in health education.

Mental Hygiene Rules

NO, it is not likely that regulation of behavior can be secured by handing out a set of " rules." As a matter of fact, few " rules " of mental hygiene as yet exist. Attempts in the past to place such " rules " in the hands of school children, adolescents or adults have invariably degenerated into the quotation of time-worn platitudes, as sterile as they are absurd. " Cheer up," " Think pleasant thoughts," " Don't worry," and a host of similar admonitions in the hearty voice of the professional Pollyanna are merely depressing to some people in need of mental hygiene, but irritating to others.

Platitudes are not mental hygiene. Exhortations do not relieve maladjustments. There are no royal roads to learning in this matter. There are no short cuts to mental health.

These are some of the reasons why leaders in the field of mental hygiene discourage most well-meant attempts to create courses in mental hygiene that can be given to school children and adolescents. To impart mental hygiene effectively, both the teacher and the taught should have behind them a reasonable measure of life experience, some knowledge of their fellow men, and, most essential of all, a modicum of personal objectivity that will permit them to apply to themselves, without too much emotional bias, the material being taught. Of such backgrounds children, most adolescents, and not a few chronologic adults possess all too little to make feasible the giving of mental hygiene instruction directly in its raw state.—*Mental Hygiene Bulletin,* Oct., 1929.

What O'Clock Is It in Industrial Hygiene?*

FRANK L. RECTOR, M. D., FELLOW A. P. H. A.

Executive Secretary, Chicago Medical Society, Chicago, Ill.

THE title of this paper suggests that it should at least be timely, but to interpret the present and future of industrial hygiene it will be necessary to sketch in briefly some of the high lights of the background of this important branch of medical and public health work.

Industrial hygiene differs from personal and community hygiene, or sanitation, in that it is a combination of both applied over a limited area, and involves a variety of problems, the majority of which are concerned with the environment of the worker, the processes on which he is engaged, and the materials with which he works.

Industrial hygiene is not a new medical entity. Its problems have been recognized and written about for more than 200 years. Some of the observations made in the earliest years of its history by Ramazzini and others hold true at the present time. The effects of unfavorable working conditions on the human body have always been the same and will continue until they are brought under control by engineering or other protective measures.

The greatest stimulus of modern times to further investigations in the field of industrial hygiene has been the enactment of workmen's compensation laws in the various states. The passage of these laws for the first time gave a definite economic urge to the study of industrial conditions and environment. When the employer could save money by studying the operations of his business from the standpoint of hygiene and health, he was not long in undertaking it.

The first approach to this problem was through strictly medical work. Provision was made to care for the sick and injured in such a way as to hasten their recovery and return to work. Later, the place where the employee labored and the materials with which he worked were studied to see what influence, if any, these factors had upon his physical condition. Laboratory and experimental studies of raw ma-

* Address of the Chairman of the Industrial Hygiene Section of the American Public Health Association, delivered at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

terials and methods of processing were undertaken to see what part they might play in the worker's health. It is through investigations of this type that industrial hygiene has made its contribution to medical and industrial science.

I like to think of industrial hygiene not as a separate scientific entity or field of work, but rather as a part of the greater problem of industrial medicine. The hygienic aspects are surely medical in concept and in application; the industrial part is engineering, chemical and mechanical. Medical knowledge is essential to a successful prosecution of studies in this field. When the medically trained mind has unravelled the knot, it requires the application of engineering skill to complete the elimination of the hazard either in construction or the process. In no other field of medicine is there such a close relation to the engineering profession. Either profession alone is unable to find the answer, and where there has not been close coöperation between the physician and the engineer the problem has remained unsolved.

I remember being called in to check over some recommendations made by a medical man relative to a dust hazard in a certain plant. The recommendation had been made—with a tone of finality that usually accompanies a lack of profound knowledge—that the installation of exhaust fans would remove the fine dust that was causing the complaint. Should the finely divided clay be removed, however, one essential ingredient of the product of this factory would be lost. The solution to this problem was not the removal of the dust by exhaustion, an easily accomplished undertaking, but rather making dust tight the process in which it was used. Here was a medical mind trying to function in one branch of the engineering field with results of no value to the practical solution of the problem in hand. Results as hopeless are produced with a similar application of engineering knowledge in the field of medicine.

Today, more than ever before, there must be close coöperation between engineering skill and medical knowledge in the solution of industrial hygiene problems. Industrial medicine is getting further and further away from the curative, and nearer and nearer to the preventive aspects of the relation of the worker to his work. Increased efforts are being made to see that men are placed at work for which they are best fitted, and fitness is being determined more carefully each year. Medical knowledge regarding materials worked with and processes employed is constantly accumulating so that in time there will be little excuse for exposing workers to unfavorable conditions.

In the vast majority of cases employers are anxious to provide the

best possible conditions for their workers. Like the average human being, they are inclined to conservatism, especially after being induced by loud talking but short performing idealists to undertake an impractical step designed to bring about the millennium in all branches of industrial relations. It is good business to keep workers well and steadily employed. It is poor business to maintain conditions that militate against steady employment. Therefore, there is every inducement for the employer to provide suitable working conditions for those in his employ. In few cases is the employer capable of determining for himself what are the best hygienic conditions to maintain in his factory or workshop. Means are usually at hand or are easily available whereby he can know his hygienic rating. His plant physician can determine for him where his greatest hazards exist, and his engineering department can provide the necessary corrections if they lie in his physical equipment. The correction of the human equipment is the function of the physician.

In the minds of some investigators, the responsibility for all evils of industrial hygiene, as well as their correction, rests with industrial management. This is but a part of the story. The worker has definite responsibilities in these matters often as great or greater than has management. Only moral suasion and threat of discharge can be brought to bear on those who fail to take advantage of sanitary facilities provided for their care.

A fact bearing largely on the worker's fitness and often lost sight of is that he is in the industrial environment but 8 hours daily, the other 16 being at his own disposal unsupervised and uncontrolled as far as his industrial relationships are concerned. The manner in which he spends his extra-industrial time must have considerable influence on his ability to carry on his regular daily work. The domestic environment, recreation habits, and dietary customs of the worker, all affect seriously his industrial capacity and efficiency. "Blue Mondays" are still common in the experience of many employers.

Turning to the entire industrial health field rather than the more restricted area of industrial hygiene, we find many interesting problems awaiting solution. One of the most important is the absorption of the sub-standard worker into the industrial scheme where he will become and remain a productive and contented member of society. By sub-standard is meant the individual subnormal from the standpoint of health as well as the person suffering from personal handicaps. It seems to me that this group is worthy of special consideration, for if its members cannot obtain employment to maintain an

independent existence they must become public charges. For this reason every effort should be made to place such workers where they will not be a danger to themselves, to others, or to property. They should be subjected to a careful examination before employment, not for purposes of rejection but to find out what they can do without injury to themselves or their employers.

When such examinations are made primarily for the purpose of exclusion, without taking into consideration the ability of the one rejected to obtain employment elsewhere, it becomes the prostitution of industrial medical procedures to the financial gain of the employer. Conscientious physicians will not lend their abilities to such undertakings. Many times physical defect is no bar to industrial employment, and when a potential worker is rejected because of some suspicious signs shown by the X-ray in the chest, for example, with no other indications of tuberculosis, or when because of some defect of limb, sight, or hearing, he is denied employment, medical knowledge is used for purposes for which it was never intended. Many handicapped persons are not sufficiently incapacitated to prevent them from rendering useful and efficient service when properly assigned.

If these people are denied employment, to what source can they turn for assistance? Is it any wonder that soap boxes are at a premium in certain quarters for impromptu platforms from which strange and sinister doctrines are preached to the passer-by? How much better would it be if industry made every effort to absorb the useable members of this unfortunate group.

It is true that refusal of employment is often predicated on the penalty imposed by workmen's compensation laws in which the last employer is held liable for the disability resulting from further impairment of function because of injury while in his employ. Many industries would gladly make places for defective workers did not the compensation laws penalize them for so doing. In several states these laws have been amended to take from the employer the extreme penalty for permanent total disability to an already defective worker. In such states there is no barrier to the employment of such persons and many industries are now giving work to those unfortunates formerly denied employment for legal reasons.

It has been the experience of observing physicians in industry that once the sub-standard worker is fitted and adjusted to his work he becomes less a risk than the so-called "normal" individual. The explanation is that the defective worker knows his limitations and will not overstep them, while the normal worker will expose himself to dissipations and excesses of various sorts, and in times of emergency

will subject himself to strains beyond his powers to withstand. It has also been the experience of many physicians in industry that persons who have suffered a disabling sickness, such as tuberculosis, and later returned to work, are usually more careful of their physical welfare than those who have not undergone such experiences.

From these illustrations it is believed that the employment of substandard workers does not carry with it the risks usually thought inherent in such cases, and when we consider further that the employment of this group in some capacity is essential to its existence, it seems only logical that a place be found in industry for its members rather than that their care be forced upon the community.

In the past those employed in factories and workshops have been thought to comprise the large proportion of industrial workers, particularly as far as the health conditions surrounding employment are concerned. In fact, this group, consisting of approximately 12 million workers, is but a small portion of the gainfully employed who comprise more than 42 million people, according to the latest federal census. Other groups are subjected to the hazards of the industrial worker, especially those involving an hygienic or environmental factor. Trade and clerical workers have many problems in common with industrial workers and it would seem that one of the next most logical steps in expanding this work would be a study of the needs of these groups.

Much remains to be known about the chemistry of industrial processes and raw and finished products. New materials and substitution products are constantly being introduced. Their physiological action in many cases is still unknown and deserves careful study and research to determine their possible dangers.

The importance of industrial hygiene is being recognized by an increasing number of scientific organizations as well as by legislative and administrative bodies. Among the more important scientific bodies taking official notice of the industrial medical field may be mentioned the following: American Association of Industrial Physicians and Surgeons, American Medical Association, American College of Surgeons, American Public Health Association, U. S. Public Health Service, American Chemical Society, state and local health departments, state and local organizations of industrial physicians, Conference Board of Physicians in Industry, private health agencies, and university and college research departments.

Among administrative groups are: U. S. Department of Labor, U. S. Bureau of Mines, state departments of labor, state industrial accident boards, International Association of Industrial Accident

Boards and Commissions, American Federation of Labor, American Association for Labor Legislation, Association of Government Labor Officials, American Management Association, National Safety Council, National Industrial Conference Board, trade and manufacturing associations, and life and accident insurance companies.

This incomplete list, covering as it does scientific, governmental, national, state and local groups and organizations of employees and employers, gives some indication of the widespread interest being exhibited in this branch of medical service.

Industrial medical and health service has not yet reached its peak of fulfilment, nor will it do so until all known sources of preventive medicine have been brought into play. We have still far to go in the physical examination of workers and the placing of them only on jobs they are able to carry. A better control over the community life of the worker and his recreation hours away from the workshop must be brought about. This latter responsibility is not that of industry, except in those cases where the industry provides all the available community activities. This control will come largely through the education of the worker to an appreciation of proper health values.

The employer's responsibility and contribution to this work rests largely on the provision of safe and sanitary working conditions. He can also at a minimum of expense make possible the provision of adequate diagnostic facilities for all but the most unusual types of illness and disability, and by this means provide an aid to the private practitioner for the better and more intelligent handling of his cases.

The health officer and the professional health worker enter this field by coöperative efforts in solving and controlling community health problems. Improvement of community sanitation and food supplies, the control of communicable diseases, the education of the worker and his family in matters of health and social welfare, are a few of the more important points of contact between the health officer and the industrial worker and management.

Space does not permit of further elaboration of these subjects. Questions of costs and organization cannot be discussed, except to say that the majority of physicians doing industrial work are not accorded the place in the organization scheme of the companies they serve that their abilities and responsibilities deserve; neither are they receiving a financial return in any way commensurate with their responsibilities. As a result, industry is getting just what it is willing to pay for, no more and no less.

While many problems in industrial hygiene have been solved, many more await solution. As industrial processes change, new factors

influencing the health of workers will be introduced. Secretary of Labor Davis said in his Labor Day speech that the working man would continue to work fewer hours, with more added to his leisure time. After having completed a survey of all federal and state prisons and adult reformatories, I am of the opinion that in many cases there is already too much leisure for certain classes. This changing condition has brought about problems of health and social welfare, and others will arise as the mechanization of industry continues, until all need for workers will have been overcome, and industry and other measures for human existence will be controlled by robots. There will then be nothing to do!

If I mistake not, industrial development has left its mark on our physical, mental and social makeup. Human beings as biological entities change very slowly. Hundreds and thousands of years are required for alterations of mind and body to become evident. With industry the whole scheme of activity changes literally over night. Greater changes have come about in the industrial world in the last fifty years than in the previous historical era. Not so with mankind. His biological changes during that time have been few. He is the same biological being today that he was five thousand years ago, and aside from being confused by attempts to make an adjustment to present conditions there has been no possible change in him during the last fifty years. Today he finds it an extremely difficult matter to adjust himself to the changed conditions created by the industrial environment in which he lives. His efforts to keep up with himself in the fields of labor, amusement, transportation and social customs, place a terrific strain on his mental and physical capacities.

Is it any wonder that so many succumb to the strain and fill our prisons and hospitals for the mentally diseased. Without wishing to be pessimistic, I can see only an increase in the population of these institutions until such a time as sobering influences are exerted over vast numbers of people now enjoying the freedom—so-called—which their new environment permits.

The threat of leisure is no idle one to our advancing civilization. Rightly used it can be the greatest force in the world today; wrongly used it becomes the greatest menace to our social and political institutions. Education offers the best solution to this problem, but it is a slow process. The education of the worker in matters pertaining to his physical health and social welfare offers the best hope of a satisfactory solution of the industrial hygiene problem. It will be slow work but if well done will not have to be repeated. Workers must be taught how to live as well as how to make a living.

Tabulation of Maternal Deaths, and of Causes of Stillbirths and Deaths of Very Young Infants*

HENRY BIXBY HEMENWAY, M. D., FELLOW A. P. H. A.

Medical Assistant Registrar, State Department of Public Health, Springfield, Ill.

THE underlying object for compiling vital statistics should be as an aid in the protection and permanency of the community. It is important that the data shall show or indicate the essential factors in the clearest manner. The tabulations are not intended for the purpose of satisfying an idle curiosity, and the state is justified in spending time and money in these compilations in exact proportion to the usefulness of the facts set forth.

It may be questioned whether methods now in vogue are always defensible. Is not a change demanded in some of those methods?

PUERPERAL DEATHS

Take for example the matter of tabulating maternal deaths. At present it is customary to compute the rate according to the number of living births recorded. In states which do not have a stillbirth form of certificate such cases are reported both as births and deaths. To tabulate according to live births it is necessary to separate the live births from stillbirths by inspecting the death certificates. This involves extra labor, and it is suspected that sometimes the published rates in such jurisdictions are made according to total births recorded.

In Pennsylvania it is required that stillbirths be reported both as births and as deaths, and we are informed that (*Vital Statistics Bulletin,* Aug., 1929) "they are classified, statistically at least, both as births and deaths"; yet in 15 per cent of the cases no birth certificate has been filed.

The real question is the risk of maternity, and the present method does not give the answer with the accuracy possible for two reasons:

First, there is a confusion of data. Although the divisor represents the number of living births, the dividend includes a large proportion of cases in which there was no living birth.

---

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

TABLE I

MATERNAL DEATH RATES (CLASS VIII)

		1926	1927	1928
Birth Registration Area of Continental United States	Births	1,856,068	2,137,836	
	Stillbirths (Varying minimum period)	70,716	82,931	
	Total Births & Stillbirths	1,926,784	2,220,767	
	Maternal Deaths (Class VIII)	12,168	13,837	
	Rates: Per 1,000 Births	6.55	6.47	
	Per 1,000 Births & Stillbirths	6.31	6.23	
Canada	Births	232,750	234,188	236,194
	Stillbirths (Period not stated)	4,064	7,336	7,588
	Total Births & Stillbirths	236,814	241,524	243,782
	Maternal Deaths (Class VIII)	1,317	1,300	1,325
	Rates: Per 1,000 Births	5.65	5.55	5.60
	Per 1,000 Births & Stillbirths	5.56	5.38	5.43
Illinois	Births	137,886*	133,662	129,668
	Stillbirths (After 4 mos. gestation)	4,897	4,701	4,678
	Total Births & Stillbirths	142,785*	138,363	134,346
	Maternal Deaths (Class VIII)	498	717	694
	Rates: Per 1,000 Births	3.61	5.36	5.35
	Per 1,000 Births & Stillbirths	3.48	5.18	5.18
New Jersey	Births	72,402	72,814	
	Stillbirths (All periods)	2,953	3,012	
	Total Births & Stillbirths	75,355	75,826	
	Maternal Deaths (Class VIII)	417	456	
	Rates: Per 1,000 Births	5.75	6.26	
	Per 1,000 Births & Stillbirths	5.53	6.01	
Washington	Births	23,989	23,315	
	Stillbirths (After 7 months)	719	650	
	Total Births & Stillbirths	24,708	23,965	
	Maternal Deaths (Class VIII)	180	155	
	Rates: Per 1,000 Births	7.50	6.64	
	Per 1,000 Births & Stillbirths	7.28	6.46	

* Including delayed reports to Aug. 1, 1928.

Puerperal deaths are those tabulated under International Code Class VIII, numbers 143 to 150 inclusive. Practically no death included under cause No. 143—"Accidents of Pregnancy," is connected with a living birth, and a large proportion do not represent any birth. Deaths from puerperal eclampsia frequently result before any birth occurs, and when children are born, many of them are born dead. Deaths from puerperal septicemia frequently do not represent cases of living birth, and a goodly proportion of other deaths in Class VIII are associated with stillbirths.

In a recent field study of maternal deaths in Michigan it was found that, of 819 maternal deaths studied, in 318 cases only were there live births. In 163 there were stillbirths, while in 336 pregnancies there was no issue.

Second, the present divisor is not the best obtainable. In the early days of vital statistics, when stillbirths were seldom recorded, the present method was excusable. Today in the United States and Canada stillbirth reports are legally required. The best obtainable divisor would now seem to be the total number of births recorded, both living and dead.

Table I gives the number of births, stillbirths, maternal deaths, and maternal death rates for 1926 and 1927, in the birth registration area of the United States, with the same data for the states of New Jersey and Washington, from the reports of the U. S. Bureau of the Census*; also similar data for Canada and the state of Illinois for 1926, 1927 and 1928.

Unfortunately there is a great diversity in stillbirth registration. In New Jersey all stillbirths of every period of gestation are reportable, but in the state of Washington a stillbirth report is not required for a stillborn child that has not passed the 7th month of uterogestation.

If, therefore, the maternal death rate is computed according to the number of births plus stillbirths reported, that rate would be abnormally high for a state which records only stillbirths during the 8th and 9th months of pregnancy. Other things being equal, the maternal death rate would be low for a state like New Jersey.

It follows that with every table relating to stillbirths there should be some indication as to the minimum period of gestation.

Physicians are sometimes slow in making records of births. The data for Illinois for 1926 include belated birth reports. The effect upon the maternal death rate as compared with the following years is striking.

If the present divisor of number of live births only is to be retained, justice demands that all deaths not associated with live births be eliminated from the dividend. This would introduce a new element of uncertainty, as in case of plural births, one dead and one live; the maternal death might perhaps properly be chargeable to the stillbirth, though it was associated with a live birth.

The true estimate of the risks of maternity must be found in using as the divisor the total number of pregnancies. This is not generally

* I wish to acknowledge the kindness of Dr. T. F. Murphy of the U. S. Bureau of the Census in furnishing advance data for 1927.

possible. A good divisor would be the number of confinements. Using data given in the "Preliminary Report" for the Dominion of Canada for February, 1929, the maternal death rates are as follows:

Per 1,000 Live Births	5.78
Per 1,000 Confinements	5.65
Per 1,000 Live and Dead Births	5.58

Unfortunately the number of confinements is not easily obtainable in published reports. It involves clerical work which many offices are not able to give on account of limited office forces. The next choice would be to use the total of live births and stillbirths, plus all deaths recorded for Class VIII in which no birth has been recorded. This seems hardly practicable. Practically, today the best divisor for this purpose is therefore the total number of living births, plus all stillbirths.

INFANT DEATHS

In the *Pennsylvania Vital Statistics Bulletin* for June, 1929, it is said, speaking of "old age":

> The acts of man are traditionally in seven ages, but it is the privilege of the statistician to reduce the number to five, as in the series of articles of which this is the last. In each age, mortality as well as personality presents characteristic features. In infancy the chief causes of death are premature birth, congenital debility and malformations, and certain acute infections which are more dangerous to the very young than to older persons.

In point of fact there seems to be a great deal more difference in the causation of deaths of infants under 1 week of age, as compared with those of 1 month to 1 year of age, than there is between the latter class and children of school age. Infant deaths should therefore be divided into two classes, making a total of six ages instead of five, as referred to above.

In the study of the deaths of very young infants, is the present statistical usage satisfactory—particularly considering the deaths of infants under 1 week of age? It is customary to tabulate according to prematurity, difficulty of birth, defective development, and conditions associated closely with the change from the existence of fetus to that of child. But, do these records really show the true causation of the deaths? Why is a child prematurely born? Why is there a defect of development?

It will be noticed that very frequently the death certificate of the new-born infant gives a record of maternal uremia, of maternal tuberculosis, or maternal syphilis, or other diseased condition of the mother. The true cause of death is the condition which produces the

premature birth, the difficulty of birth, or the defect of development. The same is true relative to stillbirths. There is no present code which enables the statistician to tabulate these early deaths and stillbirths according to the underlying causation.

STILLBIRTHS

It is a custom in tabulating stillbirth statistics to separate urban and rural districts for comparison; to show the number of stillbirths according to months of occurrence; according to legitimacy; according to the age of the mother; according to the nativity of the mother; in comparison with the number of live births; and also according to cause of stillbirth. Most of these tabulations are as yet of little practical utility because they are not correlated with the underlying causes. The Canadian tabulation does not give the information as to cause of stillbirth.

It will be noted that the causation of stillbirths and deaths of very young infants may be divided into three general classes:

1. Maternal diseased condition
2. Conditions either of maternal formation, or maladjustment of the child causing difficulty of birth
3. Diseased condition of the child apparently not dependent upon the maternal disease

For the purposes of study, in order to prevent stillbirths and deaths of very young infants, it seems therefore advisable that the U. S. Bureau of the Census be asked to devise a special code or scheme for tabulating these deaths according to real causation.

What is here suggested is not that deaths of infants during the first week after birth be omitted from, or classified differently in, the general mortality tables, nor the infant mortality tables; but that a special tabulation be made to include these deaths with stillbirths.

Apparently, the approved form of stillbirth certificate should be changed in order to bring out the necessary facts. It should show distinctly what, if any, diseased condition of the mother was present immediately before the birth of the child; and what, if any, operative measures were used. It should show whether or not during pregnancy the mother had had any illness or injury. If difficulty of birth existed, the certificate should show clearly the nature of that difficulty. The certificate should also show if the child had probably died before labor began, or died during birth. These questions might be printed on the back of the certificate, giving ample space for full information. Similar questions might be added to the back of the certificate of death, with instructions that they be answered when the certificate is for an infant less than 1 week old.

Milk-Borne Septic Sore Throat and Scarlet Fever*

CLARENCE L. SCAMMAN, M. D., FELLOW A. P. H. A.

Deputy State Commissioner of Health, Boston, Mass.

THE first milk-borne outbreaks of scarlet fever reported in this country occurred in New York and Vermont in 1893.[1] Through 1928, eighty-seven milk-borne outbreaks of scarlet fever, and forty-five of septic sore throat have been recorded in the United States.[1-4] No doubt other unrecorded outbreaks have occurred.

The eighty-seven outbreaks of scarlet fever caused 8,368 cases with 39 deaths (data incomplete). The forty-five outbreaks of septic sore throat caused 22,431 cases with 187 deaths (data incomplete). These figures give fatality rates of 0.5 for scarlet fever and 0.8 for septic sore throat. The geographic distribution of these reported outbreaks is given in Table I.

Table III shows the probable source of infection in those epidemics in which this fact was stated. Of the fifty-six scarlet fever outbreaks, 82 per cent were said to be due to a milk handler, and 2 per cent to a diseased cow and a milk handler. Of the thirty-three septic sore throat outbreaks, 55 per cent were said to be due to a milk handler, and 30 per cent to a diseased cow and a milk handler.

Source of infection unknown	31		12	

Table IV shows certain facts having to do with two outbreaks of septic sore throat and one of scarlet fever, all of which occurred in Massachusetts during the last two years. Note how alike the two epidemics of septic sore throat were in the average number of cases per family, the attack rate, the number of cases per 100 quarts of milk sold daily, and the percentage of cases age 15 or over. In over 1,500 cases of endemic septic sore throat reported in Massachusetts from 1918 through 1928, 59 per cent were age 15 or over, a difference

of 19 per cent from the figures given in Table IV, which is statistically significant.

Godfrey in his study "Age Distribution in Milk-Borne Outbreaks of Scarlet Fever and Diphtheria,"[5] reported an unusual proportion of adult cases in milk-borne outbreaks of these diseases. This type of age distribution apparently holds for outbreaks of septic sore throat. In the Plymouth outbreak of scarlet fever there was an unusual proportion of adult cases, 43 per cent age 15 or over, compared with 16 per cent of all cases of scarlet fever reported in Massachusetts from 1923 through 1927.

Dr. Knowlton[6] of Connecticut reported a milk-borne outbreak of scarlet fever in Bristol in which "92 cases occurred among users of milk from one supply amounting to 270 quarts per day." This gives a rate of 34 cases per 100 quarts of milk sold daily, which is practically the same found in the Plymouth outbreak. The number of cases per 100 quarts of milk sold daily is a very rough figure, but it is worth noticing that the rates were about the same in the two outbreaks of each disease, and were different for septic sore throat and scarlet fever.

DISCUSSION

The Lee outbreak was without question septic sore throat. The *Streptococcus epidemicus* was isolated repeatedly from the udder of the infected cow and the same organism, identical in its cultural characteristics, from the throats of several patients and the blood of one. The clinical,[7] epidemiological,[8] and bacteriological[9] studies already published portray a perfect picture, marred only by lack of proof that a human being infected the cow.

While the Charlton[10] outbreak was clinically septic sore throat, the disease was much milder than in Lee, with few complications.

There were 2 deaths. Physical examination of the 8 cows in the herd showed, according to the veterinarian, a healed mastitis in the right rear quarter of 1 cow. Three bacteriological examinations of milk from this quarter failed to reveal infection. Four separate bacteriological examinations of the milk from each of the other cows by two different laboratories likewise were negative. The first cases—6—were reported to us on June 25. Investigation showed that 84 cases had occurred with onsets as shown in Table V.

TABLE V

SEPTIC SORE THROAT, CHARLTON—DATE OF ONSET OF CASES

Date	Number	Date	Number

15	3	22	6
16	6	23	9
17	12	24	4
18	8	25	2
19	5	Unknown	1
20	18		
	Total		84

Eighty-three of these had their onsets in a period of 12 days between June 14 and June 25. In 1 case the actual date of onset was unknown. Infection of the milk probably occurred at least 48 hours prior to June 14, and at intervals during the following 10 days.

The source of the infection was the dairyman and his family. Late in February or early in March the daughter, age 17, had an unreported case of scarlet fever. On March 30 the son, 15, had his onset, was hospitalized on April 3, and discharged and sent home as a "clean" case with throat cultures negative for hemolytic streptococci May 22. Soon after the son's return to the farm the father developed a sore throat, and his wife said he had a generalized rash. He was not seen by a physician at this time. The father alone cared for the cows, which were milked by machine but "stripped" by hand. All the milking utensils were washed in the household and not steamed. The milk was bottled and capped by hand.

The father continued to work during his illness and until Sunday, June 16. He attended to the production, handling and distribution of the milk on this morning, but went to bed in the afternoon with a sore throat which had been troubling him for some 10 days or more. He was hospitalized June 21 and died June 24 of a general streptococcic septicemia.

From June 16 to June 21 this man was cared for at home by his wife and daughter, one or both of whom washed the milking utensils, which were not steamed. In addition, the mother developed a septic

finger which was opened on June 18. On June 19, the customers were advised by the dairyman to boil their milk, but the milk was not shut off until June 21. Cultures from the blood of the dairyman and from the throats of three patients were hemolytic streptococci of the beta type, but did not have the special characteristics of epidemicus. The strain did produce a Dick toxin about one-tenth as potent as the Hygienic Laboratory standard.

The Plymouth[21] outbreak was first called to our attention on March 7, when the department was asked to investigate the possibility of a milk-borne outbreak of scarlet fever.

Investigation showed that 101 cases of scarlet fever occurred on the milk route of dealer W, and 26 on the milk routes of thirteen other dealers in the community. Of these 26 cases, 22 were shown to be due to contact, and in 4 the source of infection was undetermined.

During January and February, Plymouth reported 7 and 13 cases of scarlet fever, respectively. The January and February incidence in 1929 was about twice the average incidence for the same months for the last 5 years.

Table VI shows the dates of onset of the 127 cases occurring between March 3 and March 31 on the route of dealer W, and thirteen other dealers.

Ninety-five of the 101 cases occurring on the milk route of dealer

W came down within a period of 9 days, between March 3 and March 11. The milk was stopped on the morning of March 7, so that infected milk may have been delivered up to that date. The 6 cases occurring from March 12 on were presumably secondary. At least 5 more of the 95 cases under consideration could have been secondary on the epidemiological evidence. The peak of the epidemic occurred on the 4th day. Forty-five per cent of the cases occurred during the first 4 days of the outbreak.

Dealer W delivered about 250 quarts of raw milk a day, of which about 80 were from his own farm, and about 170 purchased from producer B. Investigation of the farm of producer B showed no infection among the milk handlers. Physical examination of the fifteen cows of producer B by veterinarians showed no evidence of garget, nor did bacteriological examination of the milk from these animals show infection. Physical examination by veterinarians of the seven cows of dealer W showed three with garget, one of which was not being milked. Cultures from the milk of the two cows with garget, which were being milked, showed beta hemolytic streptococci of the human type. One of the milk handlers of this dealer had a suspicious looking throat, a culture from which showed hemolytic streptococci of the beta type. This milk handler had a history of having had grippe some 6 weeks before. No history of scarlet fever could be obtained from him or his family. Careful examination of this family group failed to show any desquamation.

Thus, the only evidence that a human being might have infected the two cows in the herd of dealer W is that one of the milk handlers with an illness some 6 weeks before, which was diagnosed as "grippe," had a suspicious looking throat with a culture positive for hemolytic streptococci of the same type as those isolated from the udders of the two cows. When and how the infection of the cows took place is problematical.

Cultures from the milk handler, the milk of the two infected cows, and from cases of scarlet fever were sent to two different laboratories. One laboratory reported only on the cultures from the two cows. One strain showed the characteristics, cultural and immunological, of the epidemicus type, while the cultures from the other cow showed the characteristics of the scarlet fever strain. The second laboratory reported the isolation of the epidemicus type from the two cows and from nine individuals. Eight strains from individuals differed from the epidemicus type in that they showed no capsule; produced small zones of hemolysis; and showed a slight tendency to cloud the broth. In three instances both types were found in the same individual. It

was suggested that these two types of streptococci represent the smooth and rough types of the same hemolytic streptococcus.

It is our opinion that the present weight of evidence shows that milk-borne outbreaks of septic sore throat and of scarlet fever are generally the result of an infection of one or more cows by an individual carrying hemolytic streptococci of the human type. As a result of this the milk is already infected when it leaves the cow and the outbreak is due to this infection rather than to contamination of milk in the interval between its leaving the cow and its use by the consumer. With these ideas in mind, our recent investigations of these milk-borne outbreaks have been carried out with the aim of finding an infected cow or cows and also of locating the human source of the cow's infection. It is not always possible to locate both the human and the bovine source of infection, and it is almost too much to expect that both of these should be found in every epidemic. Both the person and the cow may show positive cultures for only a brief period, which may well have passed before an investigation is undertaken.

SUMMARY

Eighty-seven milk-borne outbreaks of scarlet fever have been recorded in the United States from 1893 to 1928, and 45 milk-borne outbreaks of septic sore throat 1908–1928.

Fifty-five per cent of all the milk-borne outbreaks of scarlet fever and septic sore throat recorded were in Massachusetts and New York.

About three-quarters of the recorded outbreaks of both diseases had their onsets between December and May.

In 82 per cent of the outbreaks of scarlet fever a milk handler was the probable source of infection, as compared to 55 per cent of the outbreaks of septic sore throat.

In certain milk-borne outbreaks of both scarlet fever and septic sore throat in Massachusetts there was an unusual proportion of cases age 15 and over.

In the Lee outbreak of septic sore throat a cow was found to be infected with a *Streptococcus epidemicus*.

In the Charlton outbreak (clinically septic sore throat) the source of infection was the dairyman or his family, all of whom had scarlet fever except the mother, who had a septic finger. No infected cow was found.

In the Plymouth outbreak of scarlet fever the probable source of infection was a milk handler. Two cows were found to be infected.

The bacteriological evidence showed conclusively that the Lee outbreak was caused by a streptococcus of the epidemicus type. Studies of organisms from the throats of patients in the Charlton outbreak showed them to be definitely not of the epidemicus strain, but closely related to the scarlatiniform strain.

Cultures from the Plymouth outbreak of scarlet fever, on the other hand, were reported of both the epidemicus and scarlatiniform types.

DISCUSSION

MILLARD KNOWLTON, M. D., FELLOW A. P. H. A.

Director, Bureau of Preventable Diseases, State Health Department, Hartford, Conn.

IN his excellent paper Dr. Scamman has listed 132 milk-borne outbreaks of scarlet fever and septic sore throat that have been reported in this country during the past 35 years. These outbreaks were reported from northern states. None came from further south than Maryland and the District of Columbia. Those states in the South, which, according to a recent editorial in the JOURNAL, have assumed leadership in public health, have not contributed a single outbreak to the list. Does this represent a difference in the alertness of health officials, a difference in susceptibility to the streptococcus, or a difference in milk consumption in the two sections of the country?

That three-fourths of these outbreaks should occur from December to May is not surprising. Scarlet fever is more prevalent at this time. A similar seasonal variation may be expected in the case of other streptococcus infections.

Dr. Scamman's figures show that septic sore throat has an attack rate over four times that of scarlet fever; that it attacks nearly two and one-half times the number of persons per 100 quarts of milk distributed; and that nearly double the per cent of cases are over 15 years of age. Why? Scarlet fever is more readily spread by contact. More people are immune to scarlet fever, especially in the higher age groups. Fewer susceptibles—fewer cases! Do you agree? Or, does septic sore throat fail to confer immunity?

The Charlton outbreak of septic sore throat followed the occurrence of scarlet fever in the dairyman's family. On the assumption that any well behaved streptococcus will breed true to type, I suppose we may be justified in the view that scarlet fever had nothing to do with septic sore throat. Yet, how do we know that *Streptococcus epidemicus* is not a mutation form of *Streptococcus scarlatina?* This question appears pertinent also in connection with the Plymouth outbreak of scarlet fever where two types of streptococcus were isolated. Are *Streptococcus epidemicus* and *Streptococcus scarlatina* mutation forms of the same parent stock? Are these two microbes really, as one laboratory suggests, the smooth and rough types of the same organism? With *Streptococcus epidemicus* present in the outbreak, why did only scarlet fever cases occur?

Perhaps those of us who know nothing about the intricacies of laboratory procedure in dealing with the elusive streptococcus may be pardoned for asking ques-

tions. The practical application of epidemiology to the prevention of disease requires the translation of laboratory reports into administrative procedure. Some of us who must face these problems in our daily work would like very much to know just what is meant by *Streptococcus epidemicus*. We would be immensely pleased if the laboratory worker could inform us definitely and infallibly which streptococci are pathogenic for humans and which are not. Unfortunately, we are not quite sure about the matter at the present time. We are optimistic, however, and hope that some day we may know something about the streptococcus.

Because of its relation to procedure for disease prevention, perhaps the most important point emphasized by Dr. Scamman is that types of streptococcus pathogenic for man may also be pathogenic for the cow. Jones found in 1927 that cows may become infected with the scarlet fever streptococcus. This was confirmed by our experience in Connecticut with two milk-borne outbreaks of scarlet fever in January and May, 1928. In each case a cow was found to be infected with a streptococcus which responded to tests for the scarlet fever streptococcus. In each instance strains of streptococcus obtained from the throat of a man working on the farm, from the milk of the infected cow, and from the throats of scarlet fever patients appeared to be identical. One laboratory reported *Streptococcus epidemicus;* others reported what appeared to be *Streptococcus scarlatina*. Further confirmation of the point that the scarlet fever streptococcus may cause pathology in a cow's udder is now afforded by Dr. Scamman's report of the outbreak at Plymouth. The same point with reference to septic sore throat is illustrated by the Lee outbreak.

This is a new point, and its recognition requires a new procedure for the emergency handling of milk-borne outbreaks. As soon as epidemiological evidence justifies a suspicion that milk may be responsible for an outbreak of scarlet fever or septic sore throat, the following steps should be taken:

1. Stop the sale of suspected milk at once unless it can be pasteurized.
2. Advise boiling all suspected milk on hand at the time the milk supply comes under suspicion. Arrange to have this advice reach each customer at the earliest possible moment.
3. Before approving a pasteurization plant for pasteurizing a suspected milk supply, inspect the plant as to type of apparatus, method of operation, accuracy of thermometer used to determine temperature, and such other points as may need attention to make sure that a satisfactory heat treatment of milk handled in the plant will be obtained.
4. Examine all milk handlers by both clinical and laboratory methods, and remove from handling the milk all persons found to be diseased or to be carriers.
5. Examine all cows in the dairy herd by both clinical and laboratory methods and remove from the herd all found to be infected.

These measures should result in prompt control of milk-borne outbreaks. The best way to prevent such outbreaks is to pasteurize all milk.

Greatness

WITH new understanding we have come to realize at last what we might have known long, long ago, had history served us as it should. We have come to know that God's true princes do not always stand god-like and shining, pricked out forever from their fellows. We have come to understand great movements that sway the minds of men from our studying chance writings and sayings of mere anonymous and simple souls.—T. Wingate Todd, *Bull. Acad. Med.*, Cleveland, O.

THE CORONER'S DILEMMA—FOOD POISONING

RECENT press reports, particularly from Chicago, have called attention to the interesting possibility of poisoning from the mechanical type of refrigerators, presumably from methyl chloride gas. Many of the cases and deaths were at first regarded as food poisoning. Too often does this diagnosis appear in health department records and coroner jury proceedings, without proper and adequate epidemiological, bacteriological and toxicological investigations by the constituted authorities. Geiger and other workers in this field generally recognize two types of food poisoning. One type is due to the contamination of the food with some one of the paratyphoid group, or other bacteria derived from a human or animal carrier, or from the meat of an animal suffering with a specific infection of these germs.

Subsequent incubation of the contaminated food through insufficient cooking, refrigeration or storage allows the bacteria to grow and form a poisonous product, or perhaps in the process of heating, certain products become soluble and evidently poisonous.

The consumption of such food is followed after several hours by nausea, abdominal pain, vomiting, prostration, diarrhea, and perhaps fever. Complete recovery within 48 hours is the rule.

In making investigations for this type of poisoning, one should: (*a*) Always suspect freshly cooked or warmed over foods. Preserved foods are rarely at fault. Foods are apparently normal as to taste, appearance, odor and texture. (*b*) Make bacteriologic examination of excreta of patients and the suspected food for the paratyphoid group and other organisms. Feed mice with suspected food both directly and by stomach tube. (*c*) Make bacteriologic and epidemio-

logic search for human carriers and possible contamination from animal sources.

The other type of food poisoning is known as botulism. It is due to the contamination of the food with a specific germ known as the *Bacillus botulinus*. This is found in the soil practically throughout the world in the spore form, and as such is not poisonous.

When so-called non-acid foods, such as many vegetables, fish and meat, preserved by faulty and unsanitary methods are eaten, botulinus poisoning may occur. The symptoms usually appear within 24 to 48 hours. There may be marked muscular weakness, disturbances of vision, loss of ability to swallow and talk, constipation, rapid pulse and subnormal temperature—rarely any pain. Death occurs from respiratory failure.

In making investigations for this type of poisoning, one should: (*a*) Always suspect preserved foods, and meat products, such as sausages. Spoilage is noted in many instances. (*b*) Test suspected food for toxin by inoculation of mice, guinea pigs or rabbits. Test for type with specific antitoxin. Culture suspected food for the presence of spores, particularly if food has been previously boiled.

X–RAYS AND THE PUBLIC HEALTH

IT is by now an accepted doctrine that the greatest progress in public health is to be made in coöperation rather than in competition with the medical profession. The modern health commissioner seeks not so much to supplement as to reinforce the public health activities of his colleagues in private practice. Why should not this be as true in the field of tuberculosis control as it is, for example, in the control of venereal disease or of diphtheria? For the early diagnosis of these diseases every assistance is given by the state or the municipality. The early diagnosis of tuberculosis is of no less public importance. It is true that public health laboratories will examine and report on sputum; but in view of our present knowledge of tuberculosis we can no longer be satisfied with that as an aid to *early* diagnosis.

As Dr. Gerald B. Webb[1] has boldly stated: "Roentgen examination is the only method available for detecting early pulmonary tuberculosis." How often is this examination made? Certainly not as a "routine roentgen examination of all young adults," which is Dr. Webb's ideal. How often, on the other hand, must the practicing physician hesitate, when he does definitely need the assistance of the X-rays, because he knows that his patient can hardly bear the not inconsiderable cost?

Will not some progressive health department install a radiologist and invite the practitioners of its constituency to send all their patients suspected of tuberculosis and all contacts of active open phthisis for X-ray and expert interpretation whenever the financial status makes it impossible for this aid to be privately obtained?

The existence of public tuberculosis clinics is no more an objection to the giving of such service than is the existence of a venereal disease clinic an objection to the giving of service by laboratory tests and examinations. Moreover the assistance of the physician who is in the front trenches in the war against disease, is of much greater value to the morale of the army than is the occasional and rather haphazard injection of shock troops into the fight.

THE NEW ORDER IN HEALTH EDUCATION

ON another page we publish a letter showing the reaction of a worker to his experience on a Chautauqua Circuit which carried him over a large part of the United States in the interests of health. Even if we do not agree entirely with his views, they certainly give us food for thought.

There can be no question that healing and the relief of suffering appeal to the sympathetic, and the general public, more than does the prevention of disease. The average person has not yet learned the meaning of the term "positive health" and all that it carries in the way of joy of living and efficiency.

Nothing is further from our intention than to knock health officers. Their work is fine and indispensable. We believe, however, that they are deficient when it comes to the education of the public. Our present methods are very much like those of the agricultural experiment stations. One station, generally the government, publishes a bulletin on spraying potatoes, for example, and gives photographs of two piles of potatoes, one showing the yield from an acre which has been sprayed, and the other from one not sprayed. The same routine is followed in regard to fertilizers and many other things. Agricultural stations throughout the country perform the same experiment, and similar bulletins are issued, *ad nauseam*. That some good is accomplished no one can deny, but there is a woeful lack of originality, much wasted effort and an enormous waste of printer's ink and paper. One reads of the millions of bulletins which are sent out from Washington,

but no one knows the percentage of these that go into the waste-basket unread.

Do not our health officers follow the same general plan? Do they not use plate matter, and is not the getting out of the bulletin a task which they dread, and in which they take little interest, except for the statistical part, which they use to show the amount of work done?

We do not criticise this method entirely. When something new is brought forward, such as the discovery of the diphtheria antitoxin, the use of toxin-antitoxin, or the danger of undulant fever from unpasteurized milk, the more widely the information is spread, the better for everyone. In spite of this we are compelled to believe that there is a lack of originality in the educational programs of health officers, who are selected not because they are spellbinders or know how to edit a popular magazine, but on account of their knowledge of disease and preventive medicine. Knowledge must be available in order to be of use. It cannot be kept locked up in a strong box if it is to accomplish anything in the world. For this reason our JOURNAL conducts a department of Education and Publicity from which health officers can derive many useful hints in the art of putting things over. We all are in need of education, but the public needs it more than the profession.

The day of mystery, gold-headed canes, dress-suits, high hats and Latin prescriptions in medicine is gone. Distasteful as the truth may be, the medical man and health officer must learn something of the arts of the promoter in order to accomplish the greatest good.

INFANT MORTALITY IN OUR CITIES

WE have become so accustomed to a drop in the infant mortality rate from year to year that for a moment there is just a little pang of disappointment that 1928 was an exception. According to the *Statistical Report of Infant Mortality for 1928 in 729 Cities of the United States,* recently issued by the American Child Health Association, the rate for the cities of the country was 68.3. This represents a slight rise over 1927 when the rate was 64.9. The 1927 rate was the lowest ever attained and any perturbation over the setback in 1928 may be immediately assuaged in the realization that the 1928 rate, even though not quite so good, is still the second best on record.

The rate for "the country" is now coming to be much more significant than formerly. In 1915 "the country" was represented by the records from 10 states and the District of Columbia, which then constituted the Birth Registration Area. In 1928 "the country" was

represented by 44 states and the District of Columbia. The growth in the size of both the Death and the Birth Registration Areas is a matter of extreme satisfaction. One more state with acceptable records, Nevada, was added in 1929 so that now but 3 states, South Dakota, Texas and New Mexico, remain unrepresented in our national vital statistics.

The report, based on provisional figures from the U. S. Bureau of the Census and records from state and local officials, gives 1928 rates for each of 729 cities over 10,000 population in 1920, as well as rates for individual years since 1923. While the figures themselves are believed to be accurate, caution is urged in the interpretation placed on the rates for individual cities. Conscious public health effort is not alone responsible for the magnitude of a rate, but the presence or absence of hospitals and other children's institutions and, in the words of the report, "state of wealth, family customs characteristic of different race and nationality groups, knowledge and probably climate." It is these factors which explain why cities of the west coast and of certain middle western states have the lowest infant mortality rates and have had for years. Whether or not an unfavorable combination of these factors excuses a city for having a high rate is another matter. Eastern and southern cities would be inclined to think that it did.

Even making allowances for unusual local conditions, there is a direct challenge in the fact that where one-sixth of our cities have rates under 50, another sixth have rates over 90. The progress of the recent past is encouraging, but that should not dissuade us from continued efforts in baby life saving. There is every reason to believe that further reductions in the death rate are entirely possible and practicable.

LETTER TO THE EDITOR

To THE EDITOR:

In response to my curiosity while traveling in the mountainous region of Tennessee, a doctor directing a county health department said:

> If you mind your own business you'll find no better people in the world. About two weeks ago I was up in an isolated settlement. One of the mountaineers casually asked about this new medicine that kept away diphtheria. I explained. He said he wanted his children to have it. So I returned in a few days and there were forty children from near and far assembled to receive toxin-antitoxin. The word had passed around. They came.

Why? Is it that the primitive, native intelligence goes straight to the heart of a simple proposition? Is it a confidence in the truth of science unspoiled by suspicions engendered by its ignorant enemies, unspoiled by the patronizing mellifluousness of its friends?

One director of health in what is probably the most progressive of states says the people know too much. They are demanding of the doctors more than the doctors are prepared to give. He says the educational efforts of preventive medicine should be expended on the doctors. Contextually, his meaning is that the information contained in the leaflets and booklets, and which for the most part stays there, should be in the doctor's head, and by his voice conveyed to those who would learn. Passing this by, let us contemplate the avalanche of instruction in disease prevention constantly sweeping down on the populace. Booklets, bulletins, circulars, games, almanacs, press notices, boiler plates, posters, lectures, lantern slides, moving pictures, newspaper advertisements, exhibits, plays, health automobiles, health trains, etc., etc. How much good does it all do? Compare the results with the word of the doctor to the mountaineer.

The spoken word is conceded to be the most valuable means of imparting knowledge. In what way? To an assembled multitude? Possibly our impatience demands great round numbers, but we must remember there aren't many Ciceros or William Jennings Bryans in the medical profession. I have seen Herculean efforts put into so-called publicity for a grand public health rally presided over by medical supermen, rewarded by two or three rows of beautiful nurses, tubbed and starched, and a few doctors' wives and offspring. The nurses of course were detailed for fatigue duty, the graduates were "busy."

What keeps the multitude away? Dryness, no tabasco, not even salt. I, myself, have writhed in agony till I thought the speaker must feel my pain and liven things up a bit or quit. But no! He was enjoying himself.

So rarely does this method work that we might as well give it up. But if the deans and professors of medicine can't attract an audience, or even interest the well-intentioned few, to whom can we turn? To the family physician. If he has the knowledge and the faith he can speak to a man or woman, his own people, in the quiet of his office or the home and they will listen, believe, and do as he says. Then why don't the doctors do it? They have never been told it is part of their work. They have been trained, like the Victorian children, not to speak until spoken to. Public health, many of them believe, is distinct from their life work. They watch the health officer do their work as some railroads watch the auto-buses

carry their passengers. They, themselves, should do preventive medicine as progressive railroads have installed bus lines and increased their business.

The public has grown stale from constant exposure to health instruction. No matter how pretty or charmingly illustrated the educational literature, it can't compete in interest with a Sears, Roebuck catalogue. Would it be possible to declare a 10-year moratorium to the distributors of hit or miss health tracts? And, above all, to silence with a sledge hammer or a rope or poison that hackneyed phrase, " See your doctor," that recurs like the thump of a flat wheel every minute? If so, put the money into a sound, authoritative volume on the prevention of disease for doctors, and insist that they " See your families." Stir up every medical society in the country to give over a sufficient number of meetings to the compelling and insistent fact that modern medicine is passing through a transitional period, a period of reconstruction; that its most valuable function is prevention; that today treatment and cure, though necessary, are secondary and more or less emergency measures—and then have demonstrations in the practice of preventive medicine.

The ideal of medicine will not be reached until the doctor becomes primarily the teacher, weaving his teaching into his daily rounds, and not be, as at present, merely subjected about once a year to a bout of *paralysis agitans* as he wanders all over the domain of health before a luncheon club. His patients and friends will expect him to tell them what scientific medicine can do to keep them well, and expect him to administer it. The sound basis of modern dentistry is prophylaxis; it is an inspirational guidepost to general medicine. When the health clients of the doctor are watched and cared for through the successive periods of life, immunized at the proper time against contagious diseases, given physical examinations at regular periods and thus saved money, time, distress and heartaches, the doctor can look the world in the face because he is doing his full duty.

If the doctor will abandon the vain gesture of old King Canute and realize that preventive medicine offers greater victories over disease than curative medicine through all the centuries, it will be but a short time until official health authorities will be only administrators, guard the water and milk supplies, look after the sewage disposal, keep the statistical records, and act as a clearing house of information as to the trend of health and disease.

JOSEPH P. KANE, M.D.

ASSOCIATION NEWS

Executive Board Meeting

The first meeting of the new Executive Board since the Annual Meeting was held in New York on November 16 and 17. The principal business at this meeting of the Board was consideration of the organization of the activities of the Association under the terms of the new By-laws adopted at Minneapolis. The responsibilities of the four standing committees created by these By-laws were discussed at length and consideration given to personnel for appointment to these committees. These appointments when made will be announced in the JOURNAL.

A delegation of health officers from New Jersey waited on the Board to urge the continuance of *The Health Education Service,* pointing out that in their communities it had proved to be a most valuable asset in promoting the work of the health department. The Board referred the matter to the new Committee on Meetings and Publications, and, pending a review of the situation by this committee, authorized the continuation of the " Bulletin " to July, 1930.

The relation of the committees of the Association and its sections to the new plan of organization was discussed and decision on these matters deferred until the appointment of the new committees and their report to the Board.

Dates for the Fort Worth meeting were tentatively selected for the week of October 20 or the week of October 27, final decision to be made so that conflict will be avoided with annual meetings of other societies of interest to the Association members.

The next meeting of the Board will be held on December 6, together with the chairmen of the four standing committees.

HEALTH CONSERVATION CONTEST

Eighty-four cities representing 33 states, Hawaii, and the District of Columbia, are now officially entered in the Health Conservation Contest which opened June 20, 1929.

The Chamber of Commerce of the United States is conducting this contest to further development of national health interest. Other agencies interested in health work and realizing the immense value of the Health Conservation Contest, are urging active support of this nation-wide movement.

The purpose of this contest is to reduce economic losses due to unnecessary illness and death and to promote a constructive health program. The layman and the professional are working together enthusiastically with this aim in view.

The period of this year's competition ends on January 1, 1929. Awards for the winning cities will be made at the next annual meeting of the Chamber of Commerce of the United States. In order that the contest may be as fair as possible, a city will compete only with cities of its population class. A fact-finding schedule, dealing with the fundamental items of a community health program, has been sent to all con-

testants. A committee of health experts will grade the cities enrolled on the basis of this schedule.

The field staff of the Committee on Administrative Practice is in a position to give a limited amount of consultant service to those cities in the contest. This service is rendered without charge upon the invitation of the health officer. Fifteen cities have already taken advantage of this offer and have declared it extremely helpful in analyzing local problems and in formulating programs.

MERRILL E. CHAMPION RESIGNS

The Journal regrets to announce the resignation of Dr. Merrill E. Champion as editor of the Child Hygiene Section notes. Dr. Champion has been a contributor to this department since the resignation of Dr. Taliaferro Clark in March, 1926.

Dr. Champion is now handling child health demonstrations for the Children's Fund of Michigan in Detroit, and finds it impossible to continue the JOURNAL work.

NEW MEMBERS

Grace Abbott, A.M., Ph.B., Washington, D. C., Chief, U. S. Children's Bureau

M. Ciuca, M.D., Iassy, Roumania, Professor of Hygiene, University of Iassy (Assoc.)

Prescott A. Creelman, M.D., Charlottetown, P. E. I., Chief Health Officer

J. George Dempsey, M.D., New Orleans, La., Registrar, Vital Statistics, State Board of Health

Laura A. Draper, B.A., B.S., Medford, Mass., Assistant Director, Boston Community Health Association

Joyce Ely, Ruskin, Fla., Staff Nurse, State Board of Health

Glenn S. Everts, M.D., Philadelphia, Pa., Medical Secretary, Philadelphia Health Council and Tuberculosis Committee

Elton M. Hilton, B.S., Yosemite National Park, Calif., Sanitary Inspector, National Park Service

Elisabeth Hixon, R.N., Marianna, Fla., Staff Nurse, Bureau of Child Hygiene and Public Health Nursing, State Board of Health

George W. Hug, Salem, Ore., Instructor in Health Education, University of Oregon

Howard B. Iglehart, Seguin, Tex., Public Health Engineer, City Board of Health

Paul E. Laird, B.S., M.A., Durant, Okla., Department of Health, State Teachers College

John B. McCreary, M.D., Harrisburg, Pa., Deputy Secretary of Health, State Department of Health

Sarah McGiffert, Chicago, Ill., In charge of Health Education in City Schools

Thomas D. Maher, M.D., San Francisco, Calif., Director, Child Hygiene, City Board of Health

Benjamin F. Matheny, Clarksburg, W. Va., City Health Officer

Florence C. Owen, R.N., De Kalb, Ill., School Nurse and County Supervisor of Child Hygiene

Roe E. Remington, Ph.D., Charleston, S. C., Professor of Nutrition; Director of Food Research, State Medical College

George L. Robinson, C.E., New York, N. Y., Design and Construction of Sewage Disposal Plants and Water Supply

Joseph A. Sauls, Jr., Houston, Tex., Engineer and Director of Sanitation of Water Supply, City Board of Health

Samuel W. Tay, B.S., Honolulu, T. H., Director, Bureau of Sanitation, Territorial Board of Health

Clara T. Warne, R.N., Los Angeles, Calif., Official Organizer of Birth Control Clinics in the State

Elizabeth A. Woodworth, M.D., Minneapolis, Minn., Bacteriologist

Dorothy Worthington, M.D., A.B., White Plains, N. Y., School Physician

Dorothy E. Wright, R.N., Jersey City, N. J., Instructor in Health Education, State Normal School

Dr. Wu, Lien Teh, Director, Manchuria Plague Prevention Service, Harbin, China (Assoc.)

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

PREPARATION OF ANNUAL REPORT

W. H. ENNEIS, M. D.

Deputy Health Officer, Knoxville, Tenn.

FOR four successive years the Knoxville Bureau of Health has mimeographed its *Annual Report,* containing on an average 100 pages, about three-fourths of which contain tables, charts and graphs. Everything in it is mimeographed, even the covers which carry a coat-of-arms and appropriate lettering.

On two occasions the material was submitted for an estimate of the cost of printing, and each time the price exceeded the amount available for this work. This condition is largely due to the charges for the reproduction of graphs, maps and charts. Two hundred and fifty copies of the 1928 report containing 89 pages were produced at a cost of 38½ cents each. These costs are itemized as follows:

Paper—pen point mimeograph (25,000 sheets)	$50.00
Stencils—108	18.00
Ink—2 lbs.	10.00
Covers	4.50
Cost of binding	13.75
Total	96.25

Labor is not included in the above figures since the work was done altogether by regular employees over a period of several weeks. During the winter of each year a number of days are so inclement as to interfere seriously with active field work of the sanitary inspectors. This time has been partly utilized by having these men operate the mimeograph machine and assemble pages, as well as do other work incident to the preparation of the report.

At the end of the calendar year practically all necessary statistical data are available for the year, as monthly progress reports are made of all activities of the bureau. The chief difficulty lies in assembling this material into graphic, tabular and narrative form for illustrative purposes.

All stencils requiring the use of the typewriter are cut by one typist who is selected because of her skill and experience with that particular kind of work. Such practice minimizes repetition and waste of material and insures a certain degree of uniformity. The person who cuts stencils for graphs and charts must have some knack for draughtsmanship.

All stencils are preserved so that during the year the material may be used in a weekly letter to physicians and as other enclosures. They are also used in lectures to classes in sanitation and in public health nursing.

For those health organizations desiring large numbers of reports for distribution, the cost of printing would certainly be less than mimeographing. To produce more than 250 copies by the mimeograph method would be burdensome and impractical. However, the experience of this bureau has been that this number of reports or less can be produced at a very reasonable price within our own organization.

AN EXPERIMENT IN MEASLES CONTROL

JOHN P. KOEHLER, M. D.

Commissioner of Health, Milwaukee, Wis.

DURING the first 6 months of 1929 there were 12,949 cases of measles reported to the Milwaukee Health Department. The epidemic reached its height on May 17 when there were 2,230 cases on hand. As usual, most of the cases were among preschool children and those in the kindergarten and lower grades.

When measles becomes epidemic in a school, very few susceptibles escape. Many parents appealed to the Health Department to close the schools. Not feeling justified in doing this, the Health Department decided to try a procedure that would make it possible for children who had never had measles to remain at home. It was decided that every schoolroom that had 10 per cent or more of its children absent on account of measles be ordered closed. Only cases that were reported during a period of a week were counted. The children attending these infected rooms were not sent home until the close of school at noon or in the afternoon. This was done to avoid any unusual disturbance in school. An exclusion slip was handed to every pupil, informing parents that he was excluded for 2 weeks unless a blank certificate which accompanied the exclusion slip was filled out and signed by parent or guardian stating that the child had had measles, in which case he was permitted to return to school at once.

This procedure was carried out from May 5 to June 13 inclusive. Practically no complaints were made against this new practice by the school authorities, teachers or parents. Children who were excluded were ordered to remain at home, away from all other children, but their homes were not placarded. This procedure was carried out in 57 parochial and public schools, and in 128 classes, distributed as follows: 26, kindergarten; 64, 1st grade; 34, 2d grade; and 4, 3d grade.

The enrollment of the various rooms that were closed was 5,104. The number of cases reported from these rooms before they were closed was 995. There were 3,480 excluded, of whom 2,408 returned to school with certificates stating that they had had measles; 1,072 remained at home because they had never had measles. Of the number that remained at home for 2 weeks, 171 developed measles. Of the 2,408 that were permitted to return to school because they brought certificates, 42 developed measles. Out of the total number excluded for 2 weeks, 11 developed measles after they were permitted to return again to school. The 42 children who were certified as having had measles and who developed the disease later, were mostly from schools in poorer neighborhoods. Forty-two is not a large number and speaks very well for the honesty of parents. The fact that only 11 children developed measles after their 2 weeks exclusion from school, proves conclusively that either most of the children that were excluded were immune or that there was no further exposure after they returned to school. In no case was it necessary to close a room for a second time.

About 2 weeks after this practice had been inaugurated we noticed a decline in the number of measles cases reported. Whether this decline was due to the fact that the epidemic had run its course, or to the isolation of sup-

posed susceptibles, is difficult to determine. We believe, however, that the experiment was well worth trying if for no other reason than that it permitted parents to keep their susceptible children home without having any difficulty either with the children or with the school authorities.

The tendency of the health officer in the past has been to do nothing that might interfere with the school attendance of a child. We will probably all agree that nothing is gained in closing schools during epidemics, but wherever it is possible to isolate susceptibles in highly infected rooms, it is at least worth trying.

This same procedure has also been used by the Milwaukee Health Department in connection with an epidemic of scarlet fever in one school. All children were excluded and only those that showed a negative Dick test were permitted to return. The same practice might also be used in the control of other contagious diseases.

LABORATORY

C. C. YOUNG, D. P. H.

NOTES ON LABORATORY TECHNIC

PHILIP H. LOHREY AND JOHN J. DUNN, JR.

Bureau of Bacteriology, Baltimore City Health Department, Baltimore, Md.

THE following short notes record some results which we have found helpful and which may be of use to other laboratories.

We have found in the first place that beef extract can be substituted for the beef infusion used with satisfactory results in the manufacture of Loeffler's blood serum. In cultures from 100 throats containing the diphtheria bacillus the diphtheria bacillus grew on beef extract serum in every case as well as on beef infusion serum, and the growth was as luxuriant in one case as in the other. The beef infusion broth is much more expensive, and the use of beef extract broth lessens the danger of contamination, since it can be made up in smaller quantities. We have therefore adopted this method, as recommended in Wadsworth's *Standard Methods,* in place of the more troublesome beef infusion method.

We have also found it quite convenient to sterilize wooden swabs for throat work in lots of 10, 25, 50 and 100. These swabs can be used by throat inspectors in houses to be released from quarantine, and in mass cultures taken from institutions, without any material waste of swabs, owing to the different number of swabs in the various packages. These bundles are wrapped in brown paper and folded so that they can be sealed with gummed paper in such a way as to prevent contamination.

Berry and Smeaton[1] showed that many specimens of sputum from tuberculosis negative by the direct smear were found to be positive by the Kinyoun method with antiformin and ligroin. Since many laboratories apparently still use the direct smear we thought it might be advisable to call attention to the above work, and also

to describe some comparative work between the direct smear and the Kinyoun method which we have carried out. The Kinyoun specimens were stained by the Ziehl-Neelsen and the ordinary smears by the Schulte-Tigg[2] method.

In 50 examinations of suspected tuberculous sputum we found 14 positive by both methods. We counted the number of tubercle bacilli present in 50 fields, and found that the Kinyoun method yielded 2,606, while the direct smear gave only 1,407. Most of the Kinyoun specimens showed more organisms than the direct smear, although occasionally the latter showed a few more organisms than the former. Such contrasts, however, as 250 bacteria per 50 fields by the Kinyoun method and 63 by the direct smear, 356 to 4; 200 to 13; and 75 to 20, show that specimens of sputum prepared by the Kinyoun method usually contain far more bacteria per 50 fields than those by the direct smear. In early and arrested cases particularly, the chances of finding a few organisms are greater when the Kinyoun method is used than when the direct method is employed.

THE DIAGNOSIS OF *BRUCELLA ABORTUS* INFECTION IN THE UDDER OF THE COW*

J. P. TORREY

Department of Bacteriology, Michigan State College, East Lansing, Mich.

THE relation of *Brucella abortus* to public health is being recognized by more people all the time. The fact that man may become infected by drinking milk which contains *Br. abortus* has been well established and furnishes a problem which concerns public health men.

The available means of eliminating milk infections are not always practiced and cannot be applied in many cases. Pasteurization is not practical under rural conditions, and is not effective unless properly done. If a clean herd is desired for raw milk it is the practice to identify the infected animals by blood serum reactions rather than bacteriologic examinations, since guinea pig inoculations and cultural methods are slow and expensive. However, the sale of all cattle whose blood reacts to the agglutination test for the purpose of eliminating those animals excreting *Br. abortus* in their milk is not necessary since, in the writer's experience, only 50 per cent of the animals which show a blood reaction carry the *Br. abortus* organism in the udder.

By the application of the Huddleson rapid agglutination test to the milk, practically all animals carrying *Br. abortus* in the udder can be detected. The first few streams from each quarter are drawn into clean test tubes or vials. The strippings should never be used. A composite sample is of little value since only one quarter may be infected. About 3 drops of rennet are then added to the milk and mixed thoroughly. The tube may be put either in an incubator at 37° C. or in warm

* No. 19 (N. S.) Mich. Agr. Exp. Station.

water at about 40° C. If the tubes can be placed in a slanting position, the curd will settle to one side and clear milk serum, with which the test is made, will separate. Serum will form in about 2 hours and may then be used the same as blood serum in the rapid test described by Huddleson.[1] Tests may be made as soon as the serum separates; but, if the sample can be placed in an icebox or cold place, the fine particles of curd will settle and leave a much clearer serum. Sour milk will give an unreliable test. Milk in which the curd has become partially digested cannot be used as this interferes with the test.

This test may be used by an experienced person at the owner's barn to pick out the animals carrying the abortion organism in the udder. If the samples are to be sent to a laboratory, the milk serum should be allowed to form and then poured into another well cleaned bottle or vial. A few drops of an iodine or chlorine disinfectant will prevent the samples from souring.

This test is approximately 98 per cent perfect and may be employed to advantage by city inspectors and city health authorities. Its simplicity and accuracy are such that it can be recommended in preference to any cultural methods known to the writer.

The experimental data on which the above discussion is based will appear in the near future.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Residence Influence on Cancer Deaths in New York State—This is a study of the influence that residence has on cancer death rates recorded in New York State in 1926 and 1927. The number of deaths from all forms of cancer in the entire state for those 2 years was 27,889; of these 14,479 occurred in New York City, and 13,410 elsewhere in the state. Of the total deaths in New York City, 14,265 were residents of the city and 214 were residents of the rest of the state. The upstate total of 13,410 included 215 New York City residents. The number of cancer deaths in 1926 and 1927 for the various state institutions which are regarded as separate registration areas, numbered 215, all but 32 of them being in hospitals for the insane. The total of recorded deaths from cancer in the state, exclusive of New York City, included 17 residents of foreign countries and 204 residents of other states.

The rates for the urban and rural sections, exclusive of New York City, were affected considerably by the residence element. The number of deaths for the urban district, exclusive of New York City, was 8,441 and of these 7,570 were urban residents, 70 residents of New York City and 801 residents of rural New York. Taking into account the 138 urban residents who died in New York City, 229 in the rural territory and 79 in institutional districts, the total deaths of urban residents numbered 8,016. The recorded urban rate was 125.8 per 100,000 population, the resident rate 119.4. Deaths recorded in rural New York numbered 4,754 and of these 4,456 were rural residents; 69

residents of New York City, and 229 residents of urban communities. These in addition to the 921 who died in other parts of the state made the total resident rural deaths 5,377.

The recorded death rate of rural New York was 116.7 as against 132.0 for the resident rate. Rural residents who died in urban territory represented 15.2 per cent of all rural deaths from cancer while only 2.9 per cent of the deaths of urban residents were recorded in the rural part of the state. The recorded urban rate was higher than the rural rate by 7.8 per cent while the resident rate was lower than the corresponding rural rate by 9.5 per cent. The resident rate of cities from 10,000 to 25,000 considered as a group, 120.0 per 100,000 population, was lower than the recorded rate, 128.0, while in the group of small urban communities under 10,000 the resident rate was higher, 124.9 and 119.6, respectively.

The death rate of the rural territory was directly influenced by the unfavorable age composition of its population and when this fact was given due weight, the resident mortality in the rural area was found to be not higher but probably somewhat lower than in the urban part of the state.—J. V. De Porte, *Am. J. Hyg.*, 10: 201–228 (July), 1929.

Official Vital Statistics of Ireland—The Health Organization of the League of Nations has published a handbook which describes the procedure of the gathering of vital statistics in Ireland. The description is divided into 3 parts, the first for Ireland as a whole prior to 1922, and the other 2 dealing with conditions applying separately to the Irish Free State and to Northern Ireland since 1922.

Prior to 1922, a Census Act was passed during the summer months of the year preceding that in which the census was to take place. The country was divided into enumeration districts, each of which was controlled by an officer of the Dublin Metropolitan Police who acted as the local census enumerator for the district. These reports were sent to the Registrar-General in Dublin. The present systems in both the Irish Free State and Northern Ireland are continuations of the system in use prior to 1922. Among the changes introduced after the establishment of the Irish Free State, was the centralization of all economic statistics, including population statistics, under the Department of Industry and Commerce. The Statistics Act was promulgated in 1926 and provided for an enumeration of the population on April 18, 1926. The system of organization throughout was substantially the same as that prior to 1922. In northern Ireland, the department of the Registrar-General was merged with the Ministry of Finance in 1921 and the latter is responsible for duties formerly carried by the Registrar-General. A Census Act provided for an enumeration of the population on the same date as that of the Irish Free State. The country was divided into census districts and these into enumeration districts, each of which was controlled by a member of the Royal Ulster Constabulary. The actual operation was carefully organized.

Prior to 1922, living births had to be declared to the registrar within 42 days by the parents or other appropriate persons. In default of declaration within the time limit, a fine was incurred. After the expiration of 12 months, the written authority of the Registrar-General had to be obtained to effect registration of the birth. Stillbirths were not registered. The Irish Free State and Northern Ireland both introduced the system used prior to 1922. The certificates are identical to those previously used. In 1923, the Irish Free State began allocating births and deaths

occurring in institutions and elsewhere to the areas of normal residence of the mother or deceased person respectively, instead of to the area in which the death had occurred as was previously done. This same system was adopted in Northern Ireland in 1924. A person present at the time of a death or other appropriate persons were responsible for notification to the registrar of the district within 5 days after the occurrence of the death. The systems for registration of deaths in the Irish Free State and Northern Ireland are identical with that which functioned prior to 1922.

Under the old system, there were 10 infectious diseases that were compulsorily notifiable by the head of the family, or other appropriate persons and also by the medical attendant. A fine was imposed by failure of the proper person to notify the officer. The local authorities could enforce disinfection of premises, but were not obliged to do so. Vaccination has been compulsory since 1863 and every child must be vaccinated before it is 3 months old. The various measures governing the notification of infectious diseases and the procedure followed in the Irish Free State and in Northern Ireland, are substantially the same as those formerly applied to Ireland as a whole.—League of Nations: Health Organization: *Statistical Handbook Series: No. 11,* Geneva, 1929.

Health in Glasgow—The annual report for 1928 has been issued by the medical officer of health of Glasgow. The population was estimated at 1,147,108. The registered births numbered 23,649, giving a rate of 20.62 per 1,000 population, which is the lowest on record. The total number of deaths was 16,729, representing a rate of 13.7 per 1,000, which is the same as in Edinburgh. The infant mortality rate was similar to that of the previous year —107 per 1,000 live births. The maternal mortality rate of 8.79 per 1,000 births was higher than in the preceding 2 years.

The rate for infectious diseases was greater than in 1927, primarily because of the larger number of fatal cases of measles. The figures for tuberculosis were much the same as in the previous year. There were 1,247 deaths from malignant diseases, a reduction of 81.

Treatment of venereal diseases is carried out in 6 of the 13 maternal and child welfare centers. It has become the practice to take blood for the Wassermann test from every pregnant woman attending the municipal antenatal clinics. Of 584 pregnant women so examined, 29 were found to be infected with syphilis. Glasgow is the only area in the United Kingdom in which trachoma is a notifiable disease. Of 127 cases, 111 were born in the British Isles; the age group 15 to 20 had the largest number of cases. An examination of the home contacts of 33 cases notified in 1928 yielded only one case of definite trachoma.—*Brit. M. J.,* 2: 120 (July 20), 1929.

Vital Statistics for France, 1928—The minister of hygiene has published the vital statistics of France for 1928. The birth rate rose from 18.1 per 1,000 population in 1927 to 18.2. The death rate of 16.5 per 1,000 population for 1927 remained the same for 1928. The excess of births over deaths was 70,205 as compared with 65,042 in 1927. The difference in the number of births and deaths for 1928 is the highest since 1924, which shows an excess of 74,577 for the year. The total mortality for France would have decreased to a greater extent if the infant mortality had not increased from 61,817 to 68,100. During the third quarter of the year, 51 per cent more children died under one year of age in 1928 than in 1927.

The infant mortality rate in 1928 was 91 per 1,000 live births, as compared with 83 in 1927 and 97 in 1926.

The results for the first quarter of 1929 with relation to the corresponding period of 1928 have been announced. In the first quarter there was an excess of 70,205 deaths over births. In the corresponding period of 1928, there was an excess of 7,733 births over deaths, and in 1927, an excess of 32,252 deaths over births.

The excess of deaths over births for the first quarter of 1929 is due to a slight decrease in the number of births, and also to a marked increase in the number of deaths. This increase is due to the epidemic of influenza, and to an exceptionally cold winter which increased the mortality from diseases of the respiratory system.—*J. A. M. A.*, 93: 705 (Aug. 31), 1929.

Porto Rico Mortality Statistics, 1928–29—An increase in the mortality of Porto Rico was reported for the fiscal year 1928–29, particularly during the months immediately following the hurricane of September 13, 1928. The deaths directly attributed to the hurricane numbered less than 300. A comparison of the deaths registered in the months following the hurricane with the corresponding months of the preceding year showed a significant increase.

The number of deaths registered in 1928–29 was 40,890 as compared with 29,682 deaths registered in 1927–28, an increase of 11,208 deaths. The death rate for 1927–28 was 20.4 per 1,000 population as against 27.7 for 1928–29. The greatest increases for individual causes were recorded from dysentery (all forms) and influenza (all forms) which increased 882.1 per cent and 730.7 per cent respectively. Diarrhea and enteritis for all ages increased 43.2 per cent, uncinariasis 55.4 per cent, senility 53.6 per cent and congenital debility 40.5 per cent. The lowest proportional increases were recorded from cancer (all forms) 4.2 per cent, tetanus 7.7 per cent, typhoid fever 10.5 per cent, tuberculosis (all forms) 23.1 per cent and all external causes 24.6 per cent.

The increase of 1,710 deaths from diarrhea and enteritis 2 years and over was due in part to the correction of a statistical error in tabulating, children 2 years old having been included in the group under 2 years instead of in the group 2 years and over. A comparison between the mortality of 1928–29 and that of the preceding 5 years showed that the increase began in September. The average number of deaths that occurred in each month of the 5-year period was considered as normal. For July and August, 2,760 and 2,598 deaths respectively were reported and these figures corresponded to the normal. In September, there were 3,121 deaths or 675 over the normal figure. The mortality rose abruptly during the months of October and November. In December, the greatest number of deaths was recorded, 4,436, an increase of 1,744 deaths over the normal figure. The rate began to decline rapidly in January.

The average annual number of deaths registered in Porto Rico for the 5-year period, 1923–24 to 1927–28, was 30,560. The deaths for 1928–29, 40,890, showed an increase of 10,330 deaths which represented an increase of 33.7 per cent in the mortality.—M. A. Peréz, *Porto Rico J. Pub. Health and Trop. Med.*, 5: 54–58 (Sept.), 1929.

A Study of Autopsies in Haiti—A series of 700 consecutive autopsies were performed at the Haitian General Hospital, Port au Prince, from June, 1926, to January, 1928. The hospital is centrally located and the findings should be fairly representative of the mortality rate of the island.

The most outstanding cause of death

was pulmonary tuberculosis, which caused 26 per cent of the total. Lobar pneumonia caused 55 deaths. The gastrointestinal system was responsible for death in 33 or 4.7 per cent of the cases. Of these, 10 were due to typhoid in 1927 and 3 in 1928. No deaths resulted from bacillary dysentery or intestinal protozoal infestations.

Cirrhosis of the liver is not especially common, there being only 10 cases in this series and only 3 of these of the typical atrophic type. Acute nephritis is rare although chronic nephritis is quite common, causing 61 or 8.7 per cent of the total deaths. Endocarditis, both acute and chronic, is rare in Haitians. Two cases of acute mitral disease were found in terminal acute infections and 5 of chronic endocarditis.

Malignant disease was found to be just as common in Haitians as among people in the temperate zones, and the cell type differed in no way from those common to Caucasians. There were 21 deaths from malignancy in this series. Distant metastases were not common. Over 65 per cent of the cases had a clinical history of either syphilis or yaws infection at some time during life. There were 10 definite cases of yaws, 8 of which were aneurysms of the aorta, one a gumma of the brain and the other a spontaneous cerebral hemorrhage.—R. M. Choisser, *U. S. Nav. M. Bull.*, 27: 551–568 (July–Oct.), 1929.

Malaria Survey of Island of Jamaica—Malaria in Jamaica is largely, if not altogether, confined to the coastal plain lowlands. For the last 20 years the intensity of the disease over the entire island has been diminishing. The number of reported deaths from malaria from 1880 to 1900 had a sharp upward trend and after 1910 had an equally strong downward trend. A further study of incidence made from records of 19 general hospitals on the island corroborated the trends revealed by the mortality statistics. There was a decided parallelism shown between rainfall and the intensity of malaria. Of 15 separate years in which peaks of malaria incidence occurred, in 6 cases the rainfall during the same year was excessive. The seasonal distribution of malaria was studied using as a basis 61,097 cases admitted to hospitals on the island from 1910–1919. This showed the minimal incidence in May with a peak in August and a further increase until the annual maximum was reached in November.

In order to secure further data for determining the distribution and incidence of malaria, an examination of a random sample of children attending government schools was made. The entire group numbered 11,998; both sexes were included and the majority were between 5 and 14 years of age.

Splenomegaly was used as an index to the distribution of malaria. The children were tested for enlarged spleens; all of those showing splenomegaly and one-half of those with normal spleens were tested for parasites. Of the 5,742 children with normal spleens 318 or 5.54 per cent showed parasites and 256 or 36.5 per cent of the 703 children with enlarged spleens harbored parasites. From these data, the distribution of malaria was determined, schools in which parasitic or splenic indices were in excess of 25 per cent representing areas of high malaria endemicity and indices below that as areas of low or moderate endemicity. The highest splenic and parasitic indices were found under 500 feet of elevation, the next highest from 501 to 1,500 feet and generally none above 1,500 feet.—M. F. Boyd and F. W. Aris, *Am. J. Trop. Med.*, 9: 309–99 (Sept.), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Treatment of Waste Waters From Abattoirs—The writer of this article describes 2 methods found quite successful under certain conditions for the treatment and disposal of the characteristic abattoir waste water in unsewered districts.

The first method described is that of absorption by the soil under certain refinements as to preparation and cultivation of the area to be used. For a 3,000-gallon per day waste, 5 to 6 acres of land are fenced off, ploughed lengthwise and crosswise to a depth of 8″, divided into 2 sections, each of which is again subdivided into 5 plots, each plot being harrowed and graded so that the cross-section is fairly level and longitudinal section has a fall to lower end. Each plot, assuming 5 working days, will care for one day's water per week. The care and operating attention which should be given is described, particularly as to trenching, harrowing, and rotation in use of plots.

Another method found to be very successful is that of passing the waste water through a process by which the temperature is raised and then discharging it to a tank where chemical treatment is given and where it is allowed to stand for a precipitation period of 1 hour. The effluent, practically clear by this time, is then filtered through a sand bed. The necessary plant for this type of treatment comprises a steam pipe from the boiler, with valves for regulating the supply of steam, 2 ejectors, pipes and valves for regulating the flow of water to the ejectors, 4 brick or concrete tanks of varying capacity, and a sand filter bed. A rather complete description of the operating features of a plant of this kind is given, assuming a waste water production of 4,000 to 5,000 gallons per day.—W. J. Trevaskia, *Proc. of The First Commonwealth Conference on Public Health Engineering*, Commonwealth of Australia, pp. 207–211. Abstr. H. N. Old.

Studies Relative to the Significance of the Present Oyster Score—This paper is an excellent discussion of the results of a vast amount of laboratory work done in connection with the sanitary control of shellfish problems conducted by the State of Maryland. The importance of the article to those who are engaged in shellfish sanitation activities is such that the summary in full is quoted here as follows:

1. A comparison of the scores of over 400 water samples and the same number of corresponding oyster samples revealed a general trend for oyster scores to increase with increasing concentrations of colon-aerogenes group members in water. The effect of temperature on this relationship was also observed. The relationship was found to be about the same with water temperatures of 60° F. or less and above this temperature. In no case could the relationship be expressed by means of a fixed ratio. Individual oyster scores varied so consistently and widely from the hypothetical value that it was found impossible to estimate oyster scores with any degree of accuracy from a knowledge of water scores, tides, and temperature.

2. A remarkably close correlation was found between oyster scores and temperature. In considering 363 oyster samples from 2 areas a score of 50 or more was seldom found with water temperatures of 60° F. or less, whereas with temperatures of 75° to 85° F. seventy per cent of the oyster samples had scores of 50 or more and nearly fifty per cent 410 or greater.

3. The score of shucked oysters must be interpreted differently than the score of fresh shell stock. The former score indicates the degree of care in the packing process. Increased scores and total 37° C. bacterial counts have been found to result chiefly from unclean utensils. Lack of plant cleanliness and proper refrigeration permit multiplication of bacteria present in the shell stock or introduced during the handling process. Due to the fact that both the total 37° C. bacterial count and the score of shucked oysters represent a general lack of cleanliness rather than fecal contamination, the more inclusive total 37° C. bacterial count has been found particularly valuable for indicating the efficiency with which an establishment is being operated. There is apparently no reason why oysters cannot be packed in such a way as to give results just as satisfactory as those obtained in an efficient dairy for the production of certified milk.

4. The general topography of a body of water together with the effect of winds and tides causes stratification of water. In some cases, this condition may become so pronounced that water of excellent bacterial quality may be found at the surface while water grossly polluted may exist near the bottom. The average 37° C. bacterial count for all samples from the bottom was consistently higher than for samples taken just beneath the surface. Due to the fact that the water near the bottom obviously most influences oysters and the wide variations in bacterial content which may occur, the most satisfactory routine procedure is to secure bottom samples under tidal conditions judged to produce maximum pollution.

A bibliography of 14 references is appended.—C. A. Perry, *Am. J. Hyg.*, 8, 5: 694–722 (Sept.), 1928. Abstr. H. N. Old.

Sodium Aluminate as a Coagulant in Chemical Treatment of Cannery Waste Waters—The H. J. Heinz Company discharges a large volume of tomato waste which finally finds its way into the city storm sewer and then flows out into a farming community. This organic matter in the sewage putrefies rapidly and gives off offensive odors. A successful attempt was made to treat the cannery waste with lime and sodium aluminate. This solution was made up of 1 pound of lime and 0.16 pound of sodium aluminate to a gallon of water and was added to the waste in sufficient quantity to produce a good floc and to yield a pH of about 10. The effluent is stable and has no turbidity. No odor was noticeable in the ditch over a mile below the cannery.—J. A. Holmes and G. J. Fink, *Indus. & Eng. Chem.*, 21, 2: 150–151 (Feb.), 1929. Abstr. Frank Raab.

Abating Black Smoke Will Not Solve the Problem of Atmospheric Pollution—The general conception is that the abatement of black smoke prevents atmospheric pollution. This is not the case, however, because the elimination of black smoke does not necessarily prevent pollution of the air with ash particles and large quantities of sulphuric acid. In fact, the more efficient combustion of pulverized fuel leads to a marked increase in the amount of fine ash in the products of combustion. Elaborate studies reveal that the size of the suspended solids range from 0.2 to 1.5 microns. These small particles do not settle as in the case of the grosser soot and, therefore, a measure of the so-called "soot-fall" is not a satisfactory measure of the seriousness of atmospheric pollution. Studies in Cleveland indicate that there are 3 mg. of suspended solids per 100 cubic feet of air. Calculations indicate that this quantity of suspended solids amounts to 20,000 tons per year per square mile of city area when only the lower 200 feet of atmosphere is considered in the calculation and when the mean wind velocity of 11 miles an hour is utilized. The author concludes, therefore, that atmospheric pollution can only be abated by preventing ash and sulphuric acid from being discharged into the air from stacks.

Three methods of treating the products of combustion to remove undesir-

able constituents are mentioned; namely, electrical precipitation, centrifugal collection and bag filtration. It is admitted that sulphuric and sulphurous acids have not been removed from products of combustion; yet the possibility of washing the products of combustion with lime solution is mentioned. —R. D. MacLaurin, *Am. City*, 40, 5: 135–137 (May), 1929. Abstr. Charles R. Cox.

Small Filters for Household Use —Small filters for household use where there is no regular controlled supply must fulfil 2 purposes—they must clear the water of suspended matter and they must remove bacteria. It is also necessary that purification, sterilization and renewing of filter material shall be simple, convenient and cheap. No filter in continuous use remains impervious to bacteria and therefore a filter material is necessary which can be sterilized easily by boiling.

The earliest form of small filter was the clearing filter of charcoal. Then with the use of clay and porcelain came true bacterial filters. China filters in candle shape were introduced by Chamberland and with a development of this—the Berkefeld filter—with daily sterilizing a continuous germ-free filtrate can be counted on with a considerable degree of certainty. Other developments are the Doulton filter and one produced by the Seitz Works in Kreuznach, in which the filter material consists of specially prepared asbestos boards.

The chief difficulty lies in the fact that, in spite of attention and purification, bacteria grow through filter material and pollute the filtrate. This has been found to be preventable by the destruction of the bacteria in the filter by metals or metallic compounds, especially metallic silver. Bechhold has worked out an impregnating compound, the composition of which has not been divulged, and has tested its effect on filters of porcelain, kieselguhr and charcoal. The best results were obtained with porcelain filters with an average pore size of 3.8–10 microns and kieselguhr filters with somewhat bigger pores. An impregnated kieselguhr candle-shaped filter worked 5 months giving an exceptionally sterile filtrate.

Experiments were made with a filter supplied by a Hamburg firm in which the filter material was made of kieselguhr, kaolin and cement pressed into a metal case under heat while air was blown through under slight pressure. The filter core can be easily removed and renewed.

The density of the filter was tested by blowing air through while the filter was immersed in water and the greatest pore width was calculated. The average rate of permeation per sq. cm. of surface was determined by allowing tap water to run through under slight pressure.

The removal of bacteria was found to be practically complete if the filter was sterilized before filtration, but frequent sterilization was necessary.

The filter appeared good for both clarification and removal of bacteria. It must, however, be made to fit the other requirements, ease and certainty of manipulation and cheapness.—*Strunk. Tech. Gemeindebl.*, 32, 10: 144, 1929. (From Papers of Water Pollution Research Board, England.)

The Drinking Water Supply in Holland—Great advance has been made in Holland in the distribution of water since the first water works were established at Amsterdam in 1853. In 1928, all the large towns, numbering about 70, and about 400 out of the 800 rural parishes possessed water supplies. In Holland the daily consumption per head, amounting to 98.5 litres, is low in

comparison with England and America, because the industries mainly possess their own supplies of water. The majority of the water works are under public administration. In 1913 a new section for dealing with all matters relating to water supplies was established under the Public Health Department. A short survey is given of the hydrogeological conditions of the country in relation to the water supply.

Underground water is obtained from the sand-dunes in the littoral region. Iron and manganese are removed from the water before use. Natural springs are very scarce and river water is used to a great extent. All surface water is purified by sedimentation and rapid filtration before distribution. Amsterdam and the Hague have a dune underground and Rotterdam, with Delft, Schiedam, etc., have a surface river supply. Reference is made to the new purification plants for river water at Zwijndrecht and for underground water at Zutphen.—W. F. J. M. Krul and F. A. Liefrinck, *Rapport en Mededeeling v. h. Rijksbureau v. Drinkwatervoorziening. Mededeling No. 8.* (Papers of Water Pollution Res. Bd., England.)

The Grading of Milk—The grades of milk in Scotland, as laid down by the Milk (Special Designations) Order of 1923, are: (1) certified; (2) grade A (T. T.); (3) grade A; (4) pasteurized; (5) grade A pasteurized.

Briefly, certified milk is milk produced from cows which are examined at least 3 times a year by a veterinary surgeon and which have passed the prescribed tuberculin test at intervals of 6 months. The milk must be cooled and bottled on the farm and is delivered to the consumer in these bottles, and must at no time contain more than 30,000 bacteria per c.c.; no coliform bacillus in 0.1 c.c. and not less than 3.5 per cent butter fat.

Grade A (T. T.) milk is derived from cows which have passed the prescribed tuberculin test, but the milk need not be bottled on the farm by the producer. The milk must not, at any time before delivery, contain more than 200,000 bacteria per c.c. and no coliform bacillus in 0.01 c.c., and must contain not less than 3.5 per cent butter fat. It must not be heat-treated.

The requirements for grade A milk are the same as for grade A (T. T.) except that the cows need not be tuberculin tested. The cows must, however, be examined 3 times a year.

Pasteurized milk is heated to a temperature of 145 to 150° F. for one-half an hour and subsequently cooled to below 50° F. The type of equipment and methods employed must be satisfactory to the local health authority. Pasteurized milk must not contain more than 100,000 bacteria per c.c.

Grade A (pasteurized) milk is grade A milk which has been pasteurized. The bacterial count must not exceed 30,000 per c.c. and there must be no coliform bacillus in 0.1 c.c. The author discusses the various grades, giving the advantages, disadvantages, etc. —James McAllan, *J. State Med.*, 37, 4: 229–39 (Apr.), 1929. Abstr. P. R. Carter.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Report of Committee on Industrial Fatigue*—The committee's work during the past year was chiefly educational. The coöperation of some group has been hoped for that would undertake a controlled study of the relative importance of the intrinsic factors in the causation of industrial fatigue as compared to the extrinsic factors. A wide distribution of the *Bibliography on Industrial Fatigue and Allied Subjects* has been made and a second printed edition prepared comprising a bulletin of 38 pages, which includes chiefly material published in English, from January, 1921, to May, 1929. Each citation is briefly abstracted. In the citations covered the committee is impressed by the continued neglect to consider the intrinsic factors in fatigue, such as the readily recognizable physical disabilities and the widely prevailing types of "silent" sickness or organic defects that have progressed to a point affecting the working power of the organism and yet not placing the sufferer on the sick list.

Recent analysis of 100,000 health examinations of insurance policy holders made by the Life Extension Institute, the research being conducted by Edgar Sydenstricker of the Milbank Fund, in coöperation with Rollo H. Britten of the U. S. Public Health Service, shows that there is an increase in the ratio of organic impairments with increasing age. It is noted that at the age 60 the impairment rate is more than three times that at 25. Impairments may not directly affect the work curve of a group but, what Benedict has so sweetly termed "autogenic reinforcement," has to be considered—the power of man to resist the onset of pathological fatigue, and the influence of training in enabling a skilled worker to maintain for a time the peak of activity even though, in a sense, ill and tempted to slow up.

From the above, the desire for a controlled study seems obvious, yet in the literature abstracted since 1928 no important research has given consideration to the intrinsic fatigue factors. The emphasis is still upon the environmental factors.

Here and there appears a ray of light. Joshua E. Hannum in the *Journal of Industrial Psychology* indicates that at the Whiting-Davis Company there was an increased production of 27 per cent in one month's time through the correction of vision in one department employing 200 operatives. Another article by C. Fenno Faulkner in *Factory* suggests a research on what types and conditions of men are physically unfitted to withstand continuous noise. Another article by Glen L. Gardner, also in the *Journal of Industrial Psychology*, makes the statement that probably more workers break down early in life from overworking their stomachs than their muscles. The question is asked: "Is the working population of this country in an ideal physical state, and if not how far below that state on the average?" As yet we have no answer.

* Abstract of the Report (Eugene L. Fisk, *Chairman*) presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

Requests for the second edition of the *Bibliography on Industrial Fatigue* should be made to Dr. Carey P. McCord, 34 W. 7th St., Cincinnati, O.; to the Chairman of the Committee, Dr. Eugene L. Fisk, Life Extension Institute, 25 W. 43d St., New York, N. Y.; or to the Association office, 370 Seventh Ave., New York, N. Y.

Report of Committee on Lead Poisoning*—The 2d Annual Report of the Committee on Lead Poisoning of the Section on Industrial Hygiene of the A. P. H. A. was presented at the Minneapolis Meeting. It includes (*a*) Standards and (*b*) A 2-page synopsis of the Bibliography for 1928, and as such comprises 56 pages in addition to a foreword, the whole submitted as a progress report upon the standards for diagnosis, clinical forms, terminology, and symptomatology; also, compensation relations in connection with the three usual classes of cases: (1) those with positive disability; (2) those with doubtful disability; (3) those without disability.

"Standards of treatment" devotes several pages to curative treatment, divided into that for immediate toxic manifestations, and that for "deleading." Standards for industrial control lay down a definite plan of procedure with directions for workplace hygiene, rules for personal hygiene, medical supervision, and the regulations of hours of labor.

The statement concerning Bibliography is a brief summary to the effect that 265 citations were listed for the year 1928, of which 112 were abstracted to the date of the report.

A mimeographed copy of the Report may be obtained by members of the Section at the cost of 10 cents. Others may obtain copies at 50 cents each. The *Bibliography*, which comprises 27 pages with approximately 10 items to the page, will be made available in mimeograph form at 75 cents per copy. An accompanying code enables most of the abstracts to be found readily in current abstracting journals, but the committee can supply copies of the abstracts made at a cost of 5 cents each for those not exceeding ½ page, and 10 cents for those longer. All communications concerning copies of either the Report itself or the Bibliography should be addressed to Dr. Carey P. McCord, Secretary, Section on Industrial Hygiene, 34 W. 7th St., Cincinnati, O. Those interested should communicate with the Secretary at once as it seems advisable to set a date for such requests not exceeding 60 days from the publication notice hereof, in order to estimate the ultimate number of copies to be made up.

Deaths from Lead Poisoning, 1925–1927—This is an analysis of lead poisoning from the mortality statistics of various civilized countries of the world, and reaches the conclusion that as a cause of death lead poisoning is decreasing materially (valuable case records, abstracts, quotations, and tables accompany).—Frederick L. Hoffman, U. S. Bureau of Labor Statistics, *Bull. No. 488*, June, 1929, 37 pp.

Progress of Ratification of the White Lead Convention—The Convention of the League of Nations covering the control of the use of white lead has been ratified by Cuba, Bulgaria, Chile, Czecho-slovakia, Estonia, Finland, France, Greece, Latvia, Luxemburg, Norway, Poland, Rumania, Spain and Sweden. It has been ratified likewise conditionally in Hungary; approved by competent national author-

* Abstract of the Report (Emery R. Hayhurst, *Chairman*) presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

ity in Italy and the Netherlands, and recommended to competent national authority for approval in Germany and Uruguay. Various forms of legislation are also reported in progress on the measure in Switzerland and other countries.—Table Insert, *Industrial and Labour Information,* 31, 10 (Sept. 9), 1929.

Medical Services for Seamen Ashore and Afloat*—Medical service for American merchant seamen was begun in 1798 by the U. S. Public Health Service, but it was not until 1881 that a medical hand book, *The Ship's Medicine Chest,* was prepared. Millions of dollars are now spent annually for the treatment of disabled American seamen, a service without cost to them. All seamen undergo a thorough physical examination before employment. If rejected, the applicant is informed of the nature of his defects and advised to have them corrected. A health record of each seaman is kept.

It is aimed to maintain standards of general sanitary conditions, ventilation, and heating on board, and for the latter purposes blowers are supplied. Food is rigidly inspected and supplied in sufficient quantity and quality. All food handlers are carefully examined each trip. A constant campaign against bed bugs, cockroaches, rats, and mice is maintained. There is little sanitary danger in the water used by ships. Salt water should not be used in a bath as it may be polluted. Standards are suggested for bathing and laundering facilities, heads and urinals, and waste disposal.

Employment records for the past two years show that 40 per cent of the rejections are for venereal diseases, while the Service has charge of the medical treatment of seamen ashore and is also promoting an extensive educational work in venereal and related fields (the ship's hospital and medicine chest are described). All ships carrying 50 or more passengers, other than those in the cabin, are required to carry a competent physician, while emergency treatment at sea can be promptly and usually adequately administered, for which medical advice by radio is arranged.

Maritime laws cover the matter of provisions and water, complaints in regard thereto, crew accommodations, medicines and antiscorbutics, care of bodies after death, washing accommodations on new vessels, and fumigation. In vessels constructed between 1895 and 1915 the law provided 72 cubic feet, and not less than 12 superficial feet, for each seaman or apprentice in the quarters allotted to him, this space to be kept free from goods or stores of any kind. For all vessels constructed after March 4, 1915, the law requires not less than 120 cubic feet and 16 sq. ft., respectively.—Lyle Jordan Millan, M.D., Examining Physician, Bureau of Operations, U. S. Shipping Board, Washington, D. C.

A Study of Body Radiation—Rubner states (see page 20, Leonard Hill, *The Science of Ventilation and Open Air Treatment*) that "for an average man, in still air, the loss of heat is distributed as follows: Warming of inspired air, 35; warming the food, 42; evaporation of water, 558; convection loss, 823; radiation, 1,181; total loss, 2,700 kg. calories." (From these figures it will be seen that approximately 44 per cent of the body's heat is lost by radiation; 31 per cent by convection; 21 per cent by evaporation; and the small balance, by the warming up of inspired air, ingested food, and miscellaneous loss.)

The present study bears out these

* Abstract of paper read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

findings of Rubner rather closely and would appear to indicate that not enough attention has been given to the factor of body radiation as a means of heat loss in mechanical heating and ventilation schemes, which have been principally directed toward loss of heat by convection.

Some results of the present study are:

1. The radiation from the skin and clothing is approximately that of a "black body" or perfect radiator.

2. (Omitted.)

3. A cloth-covered, vertical, cylindrical calorimeter at body temperature loses in still air 60 per cent by radiation, 40 per cent by convection. A similar horizontal calorimeter loses 54 per cent by radiation, 46 per cent by convection. The human body convection loss is probably similar to this; that is, the convection loss is roughly one-third less than radiation loss, in still air and normal room temperatures.

4. Increasing air motion rapidly decreases the percentage radiation loss and increases the convectional (loss).

5. (Omitted.)

6. Increase in room temperature (which also means increase in wall temperature) produces a progressive lowering of radiation loss. The ratio, radiation loss vs. basal metabolism, decreases with increase of room and wall temperature.

7. (Omitted.)

8. At normal indoor temperature, in still air and with the subject normally clothed and at rest, body heat losses are distributed as follows:

Evaporation of water	24 per cent
Radiation	46 per cent
Convection	30 per cent

9. Air temperature falls to room temperature very rapidly as the distance from the body increases, so that at a distance of 30 cm. (about 1 ft.) no effect of the presence of the body could be detected.

10. The Abbot-Benedict work indicates that the radiation loss from a nude subject is about twice as great for a room temperature of 15° as it is for a room temperature of 26° C. This evidence does not entirely support the "suit of clothes" theory referred to by Du Bois. In explanation of this theory, he says (p. 385, 1927 Ed. "Basal Metabolism"): "A constriction of the peripheral blood vessels (occurs) and the amount of heat carried to the surface is relatively small in proportion to the heat produced. The patient really changes his integument into a suit of clothes and withdraws the zone where the blood is cooled from the skin to a level some distance below the surface."

11. Normal fluctuations in humidity indoors produce negligible effect upon the radiation loss. Our bodies radiate almost wholly between the wave lengths 4 μ and 50 μ with a maximum at 10 μ. Were the air of the room exceedingly dry, changes might be noticeable.

"Interesting and important questions concerning the comfort and welfare of children in classrooms are inadequately answered today. It is hoped that this report may in some degree help towards a better understanding of these problems."—L. B. Alrich, *Smithsonian Miscellaneous Collections,* 81, 6 (Publication 2980): 54 (tables and illustrations), Dec. 1, 1928.

Low Back Pain—The author discusses the subject from an anatomical, physiological, and evolutionary point of view, and considers, under causation, acute trauma, recurrent trauma, arthritis, malignant disease, anatomical variations, and muscular lesions (two pages of discussion accompany).—Fred C. Kidner, *Bull. Am. Assn. Indust. Phys. & Surg.,* III, 4: 1–8 (Oct.), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Influence of Inorganic Elements on Blood Regeneration in Nutritional Anemia—Reference to the use of inorganic elements in addition to iron in the treatment of anemia is found in the older textbooks on therapeutics. These include arsenic, manganese, copper and mercury. Reference is made particularly to the work of Hart and Steenbock and coworkers (Abstract in *A. J. P. H.*, 18: 1058 (Aug.), 1928) who found that copper was essential in supplementing the iron to produce hemoglobin regeneration. In view of the effect of other inorganic elements such as manganese and germanium reported by other workers, the authors studied additional inorganic elements closely associated with copper in the atomic scale. All of the work was done on young rats which had been made anemic by whole milk diet soon after weaning. Marked regeneration was noted when manganese, nickel, copper, germanium and arsenic supplemented the iron in nutritional anemia in amounts of 0.05 to 0.5 mg. daily. Cobalt, 0.05 to 0.5 mg., had a slight effect. While these experiments will confirm the observations of other workers in the ability to secure regeneration with iron alone they do not confirm the experiments of Hart and Steenbock who found copper a necessary supplement. The authors reserve final decision on this discrepancy but feel the experiments have demonstrated the supplementing action of the elements named, all of which except nickel have in the past been recognized as therapeutic agents in anemia.—Victor C. Myers and Howard H. Beard, *J. A. M. A.*, 93: 1210 (Oct. 19), 1929.

Vitamin B Content of Different Yeasts and the Wheat Breads Made from Them—In these experiments using the protective methods in pigeons or rats 3 kinds of yeast were used, one brewer's yeast and two compressed yeasts, one of which was made from molasses and the other from a grain mash. In the case of pigeons 0.4 to 0.5 gm. of dry substance of molasses yeast was necessary to protect from vitamin B deficiency, as against 0.3 to 0.4 gm. of the grain yeast. In experiments on pigeons on a vitamin B free diet of polished rice, it was found that the content of the antineuritic factor of both of the compressed yeasts was less than that of the brewer's yeast, the latter being about three times as potent. There was found to be scarcely any difference in the case of anti-pellagric or growth promoting factor.

There is a possibility that the method of manufacture of compressed yeast is responsible for the total vitamin deficiency. In the case of bread, the experiment was limited by the difficulty experienced in inducing the pigeons to consume sufficient amounts of the diet to afford vitamin B protection. Bread containing three times the usual amount of compressed yeast did not afford protection.

In the experiments with rats it was evidenced that the bread made with baking powder was inferior to that made with yeast but satisfactory comparison between the different yeasts was impossible here because of the inability of the rats to consume sufficient bread. The authors conclude that to have added more yeast to the bread would

have materially altered the fundamental character of the bread.—Arthur Scheunert and Martin Schieblich, *Biochem. Ztschr.*, 212, Band. 1–3, Heft: 80 (Aug. 31), 1929.

Influence of Vitamins A, B, D, Iron, Copper, Beef Muscle, and Liver on the Course and Regeneration from the Anemia of Rice Disease—Among the factors in experimental anemia are the vitamins, and recent work has demonstrated that not only a stronger anemia develops in the absence of vitamin B, but that its addition is followed by more prompt recovery than in the case of vitamin A.

In this experiment adult male rats, after attaining a basal weight level, were placed on special diets for a 10-week period. Eight different diets were tried, chiefly rice with various supplements, and bi-weekly observations including body weight, erythrocyte counts and hemoglobin estimation were made. Polished rice diets, cooked and uncooked, resulted in a decrease in body weight and hemoglobin level, the former proportionately greater than the latter.

Supplements of cod liver oil as a source of vitamin A were of little or no benefit. The addition of 2 per cent of compressed yeast resulted in loss of only 5 to 10 per cent body weight and of only 3½ per cent in blood count with a parallel hemoglobin figure. A supplement of iron (ferric ammonium citrate equivalent to 10 mg. iron daily) resulted in a greater loss both in weight and in erythrocyte count than with rice alone. When both iron and copper were added, there was less loss of red blood cells than with iron alone but still greater loss than in the control groups.

Comparisons of diets were made by substituting lean beef for rice, adding 2 per cent rice, substituting liver for rice and cod liver oil, substituting liver for cod liver oil alone, and the addition of yeast. These substitutions resulted in a more complete remission of the anemia observed and the greatest effect was produced by the lean beef muscle followed in order by liver, yeast, liver added to rice and yeast, yeast added to rice, copper and iron, and yeast added to rice and iron. Weight recovery was complete in 4 weeks.—R. W. Whitehead and O. W. Barlow, *Am. J. Physiol.*, 89: 542 (Aug. 1), 1929.

Anti-Scorbutic Vitamin in Cabbage Soup, Cabbage Puree, and Turnip Juice—E. Tso (*Chinese J. Phys.*, 2, 4: 403–408, 1928). In an attempt to find inexpensive sources of vitamin C for infant feeding in northern China, the author has tested the possibility of utilizing the native cabbage (Brassica pekinensis) and Chinese winter turnip (Raphanus sativus) in the form of soup, puree, or juice. The cabbage soup was prepared by cooking shredded cabbage with an equal weight of tap water for 15 minutes' actual boiling time, cooling, straining, and adding table salt to taste.

The puree was prepared by cooking shredded cabbage for 15 or 20 minutes in as little water as possible and rubbing the material through a sieve. Turnip juice was prepared by grating the entire root, including the skin, and straining it through cloth. In the feeding experiments, guinea pigs weighing from 240 to 350 gm. were fed a basal diet of soy bean meal 30, mung bean flour 30, millet meal 30, sodium chloride 1, calcium carbonate 2, and cod liver oil 2 parts, the ingredients being made into a semi-solid paste by cooking for from 30 to 40 minutes with water in a double boiler.

On this diet death from scurvy is said to take place invariably within 4 weeks. From 2 to 3 animals were used for each amount of the materials tested. The minimum amounts for

protection against scurvy and normal growth during an experimental period of 5 months were 30 c.c. daily of cabbage soup, from 5 to 10 gm. of cabbage puree, and 20 c.c. of turnip juice, respectively.—*Exper. Sta. Rec.*, 61: 193–194 (Aug.), 1929.

Rye Bread Poisoning—Report of an outbreak of illness alleged to be due to the consumption of rye bread made from rye meal contaminated with ergot (Ashby and Robertson, *Brit. M. J.*, 1: 318, 1928) was the basis of an investigation conducted by the Ministry of Health of Great Britain. The object of the investigation was to obtain facts regarding the nature of the illness, its causation, the likelihood of similar outbreaks, and preventive measures for control.

There were about 200 cases involved in this outbreak, all the victims exhibiting similar symptoms, with the exception of one that developed gangrene. In general these symptoms were developed over a period of approximately two years, the indisposition starting with coldness of the feet, weakness of the knees, pain, headaches, general marked itching of the skin, blanching of the fingers, and severe formication.

Removal of rye bread from the diet resulted in convalescence and recovery. Investigation of the source of the rye used for the breadmaking revealed that in general the rye was grown in the districts of Yorkshire, Lancashire, Cheshire, Monmouth and Essex, where these crops are seldom, if ever, free from ergot infection. It was further ascertained that the rye was neither cleaned nor screened before being ground into meal. The rye meal was used in breadmaking in the proportion of 1 part rye to 4 parts wheaten meal. Very little of the rye was used in the form of rye flour in making this type of bread. Since this outbreak, Canadian milled rye flour, said to be free from ergot, has been substituted for the meal.

As a result of the investigation, the author presents the following interesting facts: That the rye bread is eaten to a large extent in the locality under investigation by Jews, and rye for these towns is obtained almost exclusively from the ergot infested districts. Practically all of the victims in this outbreak were of Jewish extraction.

On the assumption that some of the rye consumed in Manchester contained 1 per cent of ergot, a half-pound loaf of bread containing this rye as a constituent would contain 4 to 5 grains of ergot. It is possible, therefore, that if consumed over lengthy periods, especially if the ergot were in an actively toxic state, pathological conditions might ensue.

While the samples of rye actually examined were not found to be toxic, this may be accounted for on the ground that the samples were at least 6 months old, and that the methods of analysis were faulty. The clinical characteristics of the outbreak, as far as they have been investigated, strongly support the fact that ergot was responsible.

In view of the potential danger, preventive measures were recommended to be put into operation. Rye crops should be grown with the necessary precautions to reduce the risk of ergot infection to a minimum. For human consumption, it is necessary to remove by suitable methods any small proportion of ergot which the rye may contain.—M. T. Morgan, *Brit. J. Hyg.*, 29: 60 (Apr.), 1929.

Influence of "Chilies" (Capsicum annum L.) on Digestive Functions and Metabolism—The widespread use of chilies or capsicum in tropical countries has led to this experiment to determine the effect on the gastric, salivary and other secretions. The effect of capsicum on the flow of saliva

was studied both in man and dog and found to produce copious secretions. Gastric secretion in dogs was studied and it was found that the mucous secretion was slightly increased, but it does not affect the acidity of gastric juice, nor of the gastric response. Slight increase in gastric motility in dogs was noted. In the case of individuals accustomed to eat peppery food, capsicum was without effect on the basal metabolism in amounts up to 100 gm. fresh capsicum. The opinion is offered that those accustomed to eating capsicum may have developed a conditioned reflex.—Te-Pei Feng, *Proc. Soc. Exper. Biol. & Med.*, 26: 273 (Jan.), 1929.

Experimental "Food Poisoning" in Monkeys with Living Paratyphoid Bacilli—Since in previous experiments the symptoms of food poisoning were not reproduced when enormous numbers of heat-killed paratyphoid bacilli were fed to monkeys and other animals, and no symptoms were produced when large amounts of heat-killed paratyphoid cultures were swallowed by human volunteers, it was concluded that the thermostable substance known to be toxic to animals on intraperitoneal inoculation is not the substance responsible for the gastrointestinal outbreaks with which paratyphoid bacilli are associated. Accordingly, experiments were carried out in which monkeys were fed doses of 95 to 816 billions of viable paratyphoid organisms taken from agar cultures.

The monkeys showed symptoms of illness, such as sluggishness, loss of appetite, diarrhea, and some loss of weight. In no case would death occur, and the organisms were not isolated from the blood although daily attempts at blood cultures were made.

One strain of *B. aertrycke*, originally isolated in a food poisoning outbreak in New York City, and found to produce no symptoms when heat-killed cultures were fed to man, monkeys, and other animals, was suspended in saline solution, and the suspension divided into two equal portions, one portion being boiled for 20 minutes before being fed.

Symptoms of food poisoning appeared in animals fed with living cells, not in the others. Similar positive results were obtained with an enteritidis strain, but monkeys fed with living proteus and coli strains showed no signs of illness.

In two instances monkeys in which food poisoning had been produced were fed again with the same strains three weeks later, and for the second time developed typical symptoms.—G. M. Dack, E. O. Jordan and W. L. Wood, *Proc. Soc. Exper. Biol. & Med.*, 26: 301 (Jan.), 1929.

Quantitative Studies of Responses to Different Intakes of Vitamin D—Reference is made to two recent experiments with reference to the adequacy of animal experimentation in showing the quantitative effects of vitamin D. In the work reported a diet was used containing sufficient vitamin A to make normal growth and sufficient calcium while vitamin D is abundant. Young rats were used, separated from their mothers at 21 days and 28 days. At 28 days rats were used in 3 experimental periods—28th to 56th day, 52d to 80th day, and 110th to 166th day. The 21-day rats were used in periods, 21st to 56th day, and 52d to 80th day.

Weekly determinations were made and at the end of the period femurs were dissected and ash and calcium determined.

All the criterions used in other experiments were employed here—percentage of ash, or of calcium in fresh bone, ash or calcium in the alcohol-ether extracted bone, ratio of ash to organic residue of the bone. In the experiments graded allowances of whole milk powder resulted in an increased deposit of cal-

cium in femurs, both from the time of separation to the 56th day of age, and from the 52d to the 80th day of age.

Supplementing 8 to 9 per cent of the calories with whole milk powder resulted in practically normal calcification. Similar calcification occurred with a 5 per cent of the calories supplement in from 21 to 56 days.

About 300 rats were used in this experiment and parallel results were obtained in all series, demonstrating that cow's milk contains important amounts of vitamin D. Calcium deposit of the femurs is found to be more in proportion to the supplements of vitamin D than are the weight gains.

The authors conclude that this is a definite criterion in determining proportions of vitamin D in food and that experiments have shown the advantage of such experiments upon rats immediately after separation from their mothers.—H. C. Sherman and H. K. Stieberling, *J. Biol. Chem.*, 83: 497 (Sept.), 1929.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

A NATIONAL MATERNITY SERVICE

No one is listened to with more respect, in any discussion of maternal and infant mortality, than is Dame Janet Campbell of England. The following quotation from the foreign letter page of the *Journal of the American Medical Association* offers food for thought. All probably will agree with the statements of fact in the report; some will draw back from the connotations of "subsidy," especially if of governmental origin:

> Dame Janet Campbell, senior medical officer for maternity and child welfare at the ministry of health, in her official report, declares that, out of 1,083 infantile deaths investigated, 774 of the children were either born dead or died during the first month of life, and that unless and until good midwifery, in its widest sense, is available for all mothers, many lives that might be saved will continue to be lost. Midwifery in working class homes, she adds, cannot be properly carried out unless it is subsidized in some way. Much has already been done, but not enough. Suggested remedies include a national maternity service, such as that recently proposed by the British Medical Association. Dame Janet Campbell made the investigations as the English part of an international inquiry instituted by the League of Nations. "We are sometimes inclined to think," she writes, "that the present machinery for supervising infant health and welfare is relatively complete and satisfactory. An inquiry of this kind brings home to us forcibly how much yet remains to be done before it can be said with truth that the pregnant woman and the young infant are receiving all the support and all the assistance due them from the community if the children of the nation are to multiply and prosper." After urging the necessity for improving the general sanitary environment, and particularly the housing, she also suggests as measures to secure a further reduction in the infant death rate:
>
> 1. A well organized maternity service available for every woman who cannot afford to provide adequate facilities for herself, including: (*a*) effective prenatal supervision; (*b*) adequate attendance at childbirth by well trained and competent physicians and midwives; (*c*) hospital provision for all abnormal or complicated cases, and (*d*) whatever supplementary assistance may be required before, during or after childbirth with a view to protecting and safeguarding the health of mother and child.
>
> 2. The extension and development of home visiting and infant welfare centers so that these may be fully available for all mothers, with a view to the better education of the mother and the protection of the child from avoidable disease or infection.

3. A domiciliary nursing service for minor and major infantile maladies.

4. An increase in hospital accommodation for infants who cannot properly be nursed at home.—

Foreign Letter, *J. A. M. A.*, Oct. 12, 1929, p. 1157.

HEART DISEASE A PUBLIC HEALTH PROBLEM

One of the decisions which will have to be made soon by public health workers is: How far is it wise to go in including among public health problems such matters as heart, kidney and joint affections, cancer, etc. Common sense would seem to rule out of this field the treatment of any of these diseases. How far can we successfully prevent them? The case for heart disease is well set forth by Dr. Taliaferro Clark in the article, "Heart Disease a Public Health Problem."

Pointing out that it is unfortunate that disease conditions developing slowly seldom receive adequate recognition, Clark goes on to state that "practically 75 per cent of all cases of heart disease develop in children under 10 years of age, as compared with about 12 per cent in persons over 40 years of age." Heart disease was the third highest in the list of causes of death of children during the period of 1921–1927 in the registration area of 1920.

For the prevention of congenital heart disease we must rely upon prenatal care —with what hope of success, who can say? Acquired heart disease, on the other hand, offers a more hopeful opportunity based upon hygiene and the prevention of infections, particularly rheumatism and tonsillitis. Incriminating evidence is found in the association of certain infections with damaged hearts—tonsillitis, according to Clark, leading with 66 per cent of the cases; rheumatism in 44 per cent; diphtheria in 16 per cent; chorea in 15 per cent; and scarlet fever in 12 per cent of the cases. Faulty hygiene conduces to degenerative changes in the heart muscle. Decayed teeth are now definitely under suspicion. Figures are quoted to show the sinister relationship between tonsils on the one hand and rheumatism and heart disease on the other. In such cases the indications for prevention are clear.

From the practical point of view of getting something done through administrative action, it is pointed out that adequate school health supervision is important. Stress is rightly laid upon the value of the school nurse's follow-up work in the home. Part of the article is devoted to the treatment of the cardiac case.—Taliaferro Clark, M.D., Heart Disease a Public Health Problem, *Pub. Health Rep.*, Oct. 11, 1929.

RURAL SCHOOL DENTISTRY IN NEW ZEALAND

Dental hygiene, because of the fact that dental defects bulk largest among the physical defects of school children, rightfully may claim a place in the forefront of any discussion of child hygiene.

Two items are appended, the first relating to the United States and the second to the other side of the world. We will hear first from New Zealand:

Consideration is being given by the minister for education in the dominion to the establishment of traveling dental clinics to provide for the needs of rural school children. Some years ago there was such a clinic operating in the rural districts of Auckland board area, but the department of health had stopped the arrangement on the score of expense.

Stimulated by the good results of the rural dental service provided in Queensland, the health department has reopened the question, but the expense still remains a problem. The department maintains that the service is impracticable because of its cost. In some areas, a modified service has been provided whereby a dentist employed by the department goes from school to school, making a small charge for the treatment required. Dental nurses are being more extensively employed to carry out preliminary surveys, and to refer

those needing treatment to a school dentist working at a central point for the area.

The education department has ruled that dental treatment shall be as far as possible made available to the pupils of the registered private schools as well as to those attending the free schools conducted by the government.—Foreign Letter, *J. A. M. A.*, Sept. 7, 1929.

The second item deals with a state dental program in Tennessee. It will be carried out by the state and county health departments and has the endorsement of the state dental association. Provision is to be made for county dental units, beginning with those counties having a full-time health department. The service will consist of a thorough dental examination, with treatment offered children of the fourth grade and below who cannot go to a private dentist. A nominal fee of 50 cents will be charged for each filling or extraction. A further service will be instruction in the care of the teeth. The parents will of course be notified of the findings brought out by the examinations. The state and the county will share the expense of the county unit, a minimum of $500 being put up by each.—Public Health Dental Program, Tennessee, *Child Welfare News Summary*, Oct. 19, 1929.

Two or three comments on the above items of news come naturally to mind. New Zealand is evidently worried by the cost of such service—rightly enough—and is trying to get around the difficulty by charging a fee, presumably only part of the cost. In other words, they are trying to straddle the fence between free health service for all and self-supporting service. Again, the government is offering this service to private as well as to public schools, a course open to serious objections.

Tennessee, like New Zealand, is embarking on "state medicine" (be that good or bad) in offering surgical treatment wholly or in part at public expense. One wonders about "nominal fees." Why not have everyone pay all that he can afford (a sliding scale) or else nothing at all (if the service is one that the taxpayer is supposed to be entitled to)? Nominal fees are often only soothing syrup for an uneasy governmental conscience which senses the dangers of pauperization, but not keenly enough to take effective measure against it.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Qualifications for Rural Public Health Nurses—In preparing her paper entitled "What Preparation Should the Public Health Nurse Have for Rural Work?" read before the Public Health Nursing Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, October 4, 1929, I. Malinde Havey, R.N., of the American Red Cross Washington, D. C., sent questionnaires out to State Directors of Public Health Nursing and Red Cross Nursing Field Representatives and others who had many contacts with rural nurses, asking them to state which of a given list of factors they considered most valuable, in the order of their importance, to a rural public health nurse. Here are the results:

1. Good physical and mental health
2. At least 4 months at one of the university public health nursing courses graded and approved by the National Organization for Public Health Nursing
3. Graduation from a good nursing school
4. Good home bringing up
5. Experience in county nursing under supervision
6. High school education
7. Good personal grooming

The League Calendar for 1930—This year the National League of Nursing Education calendar presents pictures of the old and new in nursing . . . "pictures of temples of healing, ancient and modern, of the transportation of the sick as it was once done and as it is done today, of early teaching and teaching nowadays."

Every nurse will want to own one of these calendars and she will find that they make acceptable gifts for her friends. The price of the calendar is $1.00 per single copy, 75 cents per copy on all orders of 50 or over, delivered in one shipment.

Proceeds of the sale will be used to help maintain and develop the activities of the National League of Nursing Education.—*Nursing and Nurses, Ancient and Modern.* National League of Nursing Education, 370 Seventh Avenue, New York, N. Y.

A New Pamphlet for Red Cross Public Health Nurses—A new pamphlet just published by the American Red Cross will prove very useful to nurses doing any kind of public health nursing work.

The Advisory Committee on the Health Program of the American Red Cross has laid down the following principles for the conduct of public health nursing activities:

1. The nursing of patients shall be carried on only under the direction of a licensed physician.

2. In advising relative to securing medical or surgical treatment, the Red Cross does not choose between individual licensed practitioners. Such choice must be left to the individual patient or to his family.

3. The Red Cross advises with reference to securing special medical and surgical treatment only after consultation with the physician, where one is available.

Chapters which employ public health nurses should request the medical society, or the local physicians as a group, to endorse standing orders which the nurse should follow in giving nursing care on her first visit to a patient, if the patient has no doctor or if the nurse cannot get in touch with the patient's doctor.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

It is understood that such orders do not authorize a nurse to continue giving nursing care after the first visit if there is no doctor in charge, and that the nurse will make every effort to get in touch with the doctor in order to secure his specific instruction in person.

In accordance with these principles every Red Cross public health nursing service should try to obtain standing orders from the local medical society or from the Chapter Medical Advisory Committee until such time as the medical society is ready to authorize them. The need for such orders is obvious.

The need of standing orders from the medical society for general, emergency and school use is explained.

Oftentimes when a chapter goes to the medical society to request a set of standing orders for the public health nursing service, the medical society does not understand just what is wanted, so a sample set of standing orders is given, a great deal of which is copied from the *Manual of Public Health Nursing*.*

In the part on "Bag Technique" the pamphlet goes on to say:

A careful and systematic procedure in the use of her bag and its equipment is a sign of a well trained nurse who respects the scientific nature of her work and takes pride and pleasure in a flawless and skillful technique. The American Red Cross expects every member of the Red Cross Public Health Nursing Service to use good "bag technique," as this procedure is commonly called.

Aside from the pleasure one takes in one's professional skill, there are three important reasons for the use of a scrupulously exact technique: one, to maintain safety, that is, to prevent the spread of disease from one patient to another and from patient to nurse; two, to expedite the work; a simple technique routinely used soon becomes a habit which frees the mind for other matters, speeds up the work, prevents confusion and saves the patient much nervous fatigue; three, to help in teaching the family; nothing is more impressive than skillful technique in teaching the family cleanliness, sickroom care and the ease of working systematically.

Sample technics are also given for various public health nursing procedures, again often quoting from the *Manual*. In the part on "Nursing Equipment" we quote the following:

Every Red Cross Public Health Nurse is expected to Carry a Bag Appropriate to and Properly Equipped for Her Work. The bag and its equipment are the tools of her art without which the nurse is greatly hindered in meeting technical standards. While the initial outlay required for their purchase may seem somewhat expensive to the Chapter it may be accepted as essential to the quality and effectiveness of the service. Any one of three standard bags is recommended for the use of Red Cross public health nurses according to the kind of work in which each nurse is engaged.

These are (1) the Stanley Visiting Nurse's Bag which is particularly adapted for use in visiting nursing; (2) the Stanley School Nurse's Bag designed for use in town school nursing but which also can be used for a limited amount of bedside nursing, and (3) the Red Cross County Nurse's Bag designed for use in county work which includes school nursing and other educational work, and also some emergency bedside nursing.

Further on in speaking about the contents of the nursing bag the pamphlet states:

The Bag Shall Contain no Other Drugs Than Those Which the Nurse Has Been Authorized to Use by the Local Medical Society or the Chapter Medical Advisory Committee and Which Are Covered by Standing Orders. This does not apply, however, to liquid green soap, alcohol, Lysol, vaseline and hand lotion which may be carried without an order.

Since the American Red Cross is in intimate touch with such a large number of public health nursing services of all kinds all over the country and is constantly working to improve them, this pamphlet is very practical and up-to-date and can very well be followed by every public health nurse whether she is paid by Red Cross funds or not.—*Standing Orders, Bag Technique and Nursing Equipment for American Red Cross Public Health Nurses, A. R. C. 721,* The American Red Cross, Washington, D. C., Sept., 1929.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Staff Members as Members—The Public Health Education Section of the A. P. H. A. is the one professional organization of all who are doing any phase of public health education. It is the place to stand up and be counted. Executives are urged to encourage membership for all staff members doing anything in education and publicity. Cannot the department or organization provide the individual memberships?

At Your Next Convention—At the next state meeting of social workers, or any state or national meeting of health workers, let's have a health education and publicity session Breakfast, luncheon or informal dinner?

If you have no other idea for a program, offer "Questions and Answers." Invite questions in advance. Have your questions written out ready to start the meeting. The audience will quickly supply more questions. The chairman can answer some questions and get the audience to help. A committee of two or three could help the chairman handle the questions.

Merely opinion questions could be answered by raising hands. How many believe so and so? How many believe something else?

Try It on Yourself—Mail a poster or car card to your own home address. Take it out from the tube—if you can get it out without tearing the poster or tearing the tube into bits. Then try to hang the poster or card on the wall. Can you keep the top and bottom flat against the wall? Surely not, because the office rolled the printed side inside. *Every rolled poster or card received for the Minneapolis headquarters display was a problem, because the roll was too tight, or because the roll was crushed, or because the printed side was rolled inside.* Try it on yourself to learn how your office handles such shipments.

Classified Health Material—A group of portfolios displayed at publicity-education headquarters at Minneapolis contained samples of material issued by health agencies on heart disease, cancer, colds, rural sanitation, diet and weight, health examinations, winter warnings and advice, summer warnings and advice. Other portfolios contained radio talks, house organs, booklets and folders. Thus was realized the classified portfolio idea we have been seeking for a year or two. The gay labels on the portfolios were lettered by Merwin-Davis, 144 East 86th St., New York, N. Y.

The portfolios have been loaned to the Community Chest, Washington, D. C. To borrow them you pay express charges. Weight 11 pounds.

"Baby-Mother Books" Are Better and Better—A group of such pamphlets and folders on the needs of mothers or babies were received in advance of the Minneapolis meeting. Text, typography and paper are improving. There seems to be too much shiny paper, lessening readability of several folders or booklets. One state department is using too small type. One folder, *Sun Baths*, omits all men-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

tion of the publisher. Why is this, please?

The collection came from the following: Department of Health, Buffalo; Iowa Tuberculosis Association, Des Moines, Ia.; John Hancock Mutual Life Insurance Co., Boston, Mass.; Ohio Department of Health, Columbus, O.; Pilot Life Insurance Co., Greensboro, N. C.; U. S. Children's Bureau, Washington, D. C.; Wisconsin Anti-Tuberculosis Association, Milwaukee, Wis.; and one unknown source.

And That Was Minneapolis—Some education-publicity workers turned up for the first time. . . . But we missed others who should have been there. . . . Our headquarters was arranged along new lines which seemed to meet with general approval. . . . We hope to make even more classified selections of publicity materials next year. . . . Diphtheria held its own with 75 at a hastily called breakfast and many visitors to the diphtheria section of our headquarters, again in charge of Mrs. Marie Kirwan, State Charities Aid Association, New York, N. Y. . . . "It" and the contest mentioned elsewhere aroused much discussion. . . . What can we offer for critical examination next year? . . . Here is the first call for volunteers as reporters for the *Daily Bulletin* at Fort Worth. . . . Now we are more than ever sure that the annual meeting is not the time for holding a local popular health exhibition. . . . And that the technical exhibits from health departments and associations should be grouped together. . . . And that the exhibits or consultation desks of national health agencies should not be scattered among the commercial exhibits. . . . And that it would be good to have more technical exhibits and more consultation desks from national agencies. . . . As usual, the milk and cleanliness groups put on pleasing and effective displays. . . . The opinion voting on exhibits was a flop with but three ballots turned in. . . . Those who ask every year that exhibits should be criticised had their chance and passed it up. . . . What kinds of publicity and educational materials would you like to see at Fort Worth?

For and Against "It"—The booklet for girls, "It" And How, already discussed in this department was the subject of a contest at the A. P. H. A. meeting in Minneapolis. The Minnesota Public Health Association, 11 West Summit Ave., St. Paul, Minn., publisher of the booklet, offered prizes for the 5 best favorable comments, and the 5 best unfavorable comments.

None of the unfavorable comments were signed. The favorable prize winners were: M. Wolff, Minneapolis, Minn.; C. P. Archer, Moorhead, Minn.; L. von D. Chandler, Hackensack, N. J.; J. H. Larson, New York, N. Y.; Orpha Hocking, Minneapolis, Minn.

The majority of the voters thought that girls would read the booklet; that the "It" appeal is not unwholesome; and that it would influence the health habits of girls. The voters stood about half and half on this question: "Are health workers past their teens good judges of what will appeal to teen-agers of today?" Single copies of the booklet for 10 cents at the St. Paul address.

From Iceland to Siam—Dr. Rene Sand, technical counsellor, League of Red Cross Societies, says:

> From Iceland to Siam, from Dantzig to South Africa, from Canada to Chile and New Zealand, there is not a single Red Cross Society which is not endeavouring to teach the masses the elementary rules of hygiene and child welfare, instructing them in the means of checking social scourges. Tracts, brochures, posters, calendars, illustrated post-cards, press articles, children's books, bulletins, lectures, cinematograph demonstrations, traveling teams,

wireless talks, models, exhibitions, playlets, pageants, competitions, health weeks, children's weeks and cleanliness weeks—all possible means are employed, even to the advice which the Argentine Red Cross has printed on match boxes. And the above does not take into account the work accomplished by the Junior Red Cross or by public health nurses. Hygiene articles are increasing in number in the National Red Cross bulletins; some of the Soci ies are even publishing special reviews devoted exclusively to health questions, such as "Hygia," published by the Greek Red Cross.—

World's Health.

What the States Are Doing—Or Not Doing—The record is for 1925, but in one instance at least there is less doing now than in the year covered by the Rockefeller report of health departments and provinces of the United States and Canada.

Here are a few high lights from the section on Public Health Education:

Organization—The state departments of health of 17 states have a separate bureau or division in charge of educational activities, while 22 states conduct the work in the executive or central administrative office. The work is in charge of the division of child hygiene in Louisiana and Texas, the division of hygiene in Massachusetts, and is divided between the divisions of child hygiene and venereal disease control in Minnesota. In Alabama, Delaware, Missouri, and New Hampshire the head of each division is responsible for promoting the educational and publicity activities of his division. Idaho does not carry on any special educational work.

Publicity—In 10 states the director of the bureau or division of public health education is also responsible for publicity, in 27 states the executive officer himself handles publicity, and in Louisiana and Massachusetts the director of the division of child welfare handles it. In Alabama, Delaware, Kansas, and New Hampshire the head of each bureau or division gives out news regarding his division. Kentucky employs a publicity reporter, Maine designates a special clerk, and Virginia employs an experienced newspaper man. The activities of Florida and Idaho are reported as quite limited.

Educational Methods—In general, the educational program of the various states provides for publicity through articles on health subjects in newspapers, magazines, bulletins, and pamphlets, and through lectures, motion pictures, and exhibits on special subjects.

Press Service—Seventeen states maintain regular newspaper service, 27 states coöperate with the local newspapers by submitting news and other articles on health subjects from time to time and 4 states report that they do not have any press service.

Each week the Illinois State Department of Health mails a 300-word story and a page of pointed paragraphs to every newspaper in the state. Pennsylvania syndicates a weekly health letter to 300 newspapers, Texas to 450 newspapers, and Virginia to 145 papers. In West Virginia once a month a column of plate is sent to the country weeklies. At the time this material is released by the country weeklies it is sent to the city dailies as "Newsgrams."

Illustrated feature stories for the Sunday papers are prepared by the bureau of public health education in West Virginia.

Special Methods of Publicity—In recent years broadcasting has become popular and state departments of health are using this method of stimulating public interest in health education. The following states reported radio talks during 1925: Connecticut, Illinois, Iowa, Maine, Missouri, New York, Pennsylvania, Tennessee, and Vermont.

Bulletins—Thirty-five state health departments publish periodical bulletins which are issued weekly, bimonthly, monthly, quarterly, or semiannually. Six additional states published pamphlets on particular subjects, and 7 state departments of health did not publish any bulletins or pamphlets in 1925. Of the 35 states issuing a regular bulletin 27 also published pamphlets on special health subjects during 1925.

Graphic Material—Thirty-eight states own motion-picture films and many of these states have projecting machines also. (The number of states having motion-picture machines is not available.) Portable exhibits on various health subjects are used by 36 of the states.

Health trucks are used in Arkansas, Florida, Mississippi, New York, Ohio, and Virginia for the benefit of the rural population. These trucks are equipped with dynamo, moving-picture projector, etc. Portable exhibits are also transported to rural districts by these trucks.

Special Exhibits—Louisiana uses portable electrical models to demonstrate various health subjects. New York has wax models which are used by the division of venereal disease control. Wisconsin has a set of large hand-painted panels in pictorial and chart form to outline the board's varied functions and activities. One set describes the latest

procedures in the control of communicable diseases, such as toxin-antitoxin vaccination and goiter prevention; another set is devoted to the work of the sanitary engineering and plumbing divisions; and another to venereal disease prevention and social hygiene. A staff artist is employed for this work.

What in this report cheers your heart?

Good Statistical Leads—Effective use of statistics in news stories is illustrated by many of the weekly press releases of the Illinois Department of Public Health.

Springfield, July 30: Instead of being stretched to greater length the life span of adults is being cut short. Mortality rates among people past 40 have increased about 10 per cent in 10 years. The percentage of all dealths in Illinois, occurring among people between 45 and 65 years, has increased from about 20 per cent in 1918 and 22½ per cent in 1920, to 27 per cent in 1927.

These statements were made here today by Dr. Andy Hall, state health director, who pointed out that the increase in average life span during recent years has resulted entirely from saving children and reducing infant mortality. Adults and especially those past 40 are actually losing ground in life expectancy compared with the situation a decade ago. . . .

Springfield, Sept. 12: Only 1 out of each 200 mothers who gave birth to children last year in Illinois failed to survive the experience, according to a statement issued here today by Dr. Andy Hall, state health director, who declared that this is the most favorable maternal mortality record ever made in the state. At the same time, Dr. Hall added, 2 out of each 3 of those who died succumbed to causes of a preventable nature. . . .

Springfield, Sept. 18: In spite of eighteen-day diet fads and the popularity of golf, a rise of 15 per cent in the mortality from diabetes last year shows that people in general are eating too much and exercising too little, according to a statement issued here today by Dr. Andy Hall, state health director. Last year 1,750 people succumbed to diabetes in Illinois, compared with 1,484 in 1928, and 1,025 in 1919, the lean war year. This increase of 70 per cent in eight years is almost exactly parallel to the rise in general post-war prosperity which has been accompanied by an unprecedented increase in rich food consumption. . . .

Springfield, Sept. 25: Accidents and tuberculosis are far and away the worst health hazards that school children have to face, accidents predominating among the grade pupils and tuberculosis among high school students. These facts were disclosed here today by Dr. Andy Hall, state health director, who pointed out that accidents and tuberculosis were responsible for 31 per cent of 4,772 deaths that occurred in Illinois last year among children between 5 and 20 years old. . .

Springfield, Oct. 23: With heart disease outdoing all other ills on the mortality calendar and the death rate from this cause in Chicago standing nearly 20 per cent above that of down-state, Dr. Andy Hall, state health director, declared in a bulletin issued here today that industry and employees generally must take a vigorous hand in a control program if the tremendous and increasing economic losses caused by cardiac disorders are to be lessened or prevented in significant degree. Nearly all of the thousands of cardiac patients can earn a substantial livelihood provided they are occupied in suitable jobs, it was pointed out. . . .

Springfield, Oct. 30: With more than 200 cases of smallpox reported from 27 different counties within the last 6 weeks, and two outbreaks of more than 30 cases each within the last 2 weeks Dr. Andy Hall, state health director, declared in a statement issued here today that the outlook for the next few months is most unpromising. While the disease is generally mild in character the quarantine period is a strict 21 days for every patient and the numerous foci are likely to result in spreading that will cause serious losses to business, especially during the holiday season. . . .

In every case the lead is followed by an interview amplifying and discussing the statistical statement. A second sheet, headed "Health Grams," carries 8 or 10 well written "filler" paragraphs. For example:

> Facts are our scarcest raw material according to Owen D. Young, who might have added that careless information masquerading as facts is our most plentiful stock in trade. If the claims of nostrum vendors and short cut cure experts were true we should soon all be supermen, and nobody would have cancer, tuberculosis or "that tired feeling."

MOTION PICTURES

Health Movies: How to Use Them, by H. E. Kleinschmidt, M.D. National Tuberculosis Assn., 370 7th Ave., New York, N. Y. *Free.* 7 mimeographed pages. "Difficulties to be Hurdled," "Types of Health Movies," "Shall the Motion Picture be Explained?" "A Word about Trailers," "Mechanics of Making Movies," etc.

"Sound Studio Slang," by Frank J. Wilstach. *New York Times.* Oct. 13 and 20, 1929. New words used in recording films.

Says the American Posture League: "A posture film is now in the making and will be issued by the Eastman Teaching Films of Rochester within the next few months." The League cooperated in the preparation of this film.

"Statistically Speaking—A Flagrant Misinterpretation," by E. R. Enlow. *Educational Screen,* 5 South Wabash Ave., Chicago, Ill., Oct., 1929. 25 cents. For those who may be tempted to quote over-enthusiastic statements as to the teaching values of motion pictures based in the Eastman experiments.

Universal Cinema Co., Indianapolis, Ind., announces collaboration with the U. S. Public Health Service in the production of pictures on mosquito control and malaria presentation: how airplanes, motor boats and other means are used; better and cheaper ways of mosquito-proofing houses; life cycle of the mosquito; and a variety of methods of control will be shown.

Sunshine from the Sea, issued by E. R. Squibb and Sons, 80 Beekman St., New York, N. Y., is "the story of two vitamins in their relation to health and beauty." Uses some color photography and animated diagrams. The synopsis sounds popular, with up-to-date scientific data.

How Science Aids in the Control of Infectious Disease, by Squibbs, illustrates immunity preparations and how they work.

It seems probable that both the above pictures will be useful for showings to health and social workers.

"1000 and One—The Blue Book of Non-Theatrical Films" (6th ed.). *Educational Screen,* 5 South Wabash Ave., Chicago, Ill. *75 cents.* Classified lists of pictures with distributors. Includes Physiology, Health, Hygiene, Child Hygiene, Nursing, Accident Prevention, Athletics, etc.

"Theatre Building and Equipment Buyers Guide." Supplement to *Motion Picture News,* 729 7th Ave., New York, N. Y. Detailed classification of equipment sources.

"Teaching Film Showing Intestinal Movement." *Trained Nurse,* June, 1929. Synopsis of new picture prepared at University of Chicago.

"This Great Peril," produced by Visugraphic Pictures, Inc., "carries home to the layman the warning that he must use the proper method to cope with the cancer menace and, above all, must guard against quack practices." Synopsis in *Campaign Notes.* American Society for Control of Cancer, 25 West 43d St., New York, N. Y., June, 1929. *Free.*

NEW PERIODICALS

The mid-monthly edition of *The Survey* has been so made over—and improved—that it is almost a new magazine.

Municipal Sanitation, edited by Abel Wolman, Maryland State Board of Health, to start publication January 1.

BOOKS AND REPORTS

Clinical Laboratory Methods—*By Russell Landram Haden, M.D. (3d ed.). St. Louis: Mosby,* 1929. 69 ill. 4 col. pls. 317 pp. Price, $5.00.

This book is a selection from standard reference books on laboratory methods of those determinations which are most commonly done in the clinical laboratory. In most cases only one method for each determination is given, this method being the one most commonly used at present. The subjects covered include clinical chemistry, bacteriology, hemotology, serology, clinical pathology, and short sections on tissue preparation and water and milk. Basal metabolism has been entirely omitted.

The most important addition to the present edition is the Kahn precipitation test which together with the Kolmer method for the Wassermann test comprises the section on serology.

A few other new methods such as the determination of indican in blood have been added.

With most of the quantitative chemical methods, tables are given from which the final results can be taken without calculations. An excellent section on preparation of solutions, standardizing of glassware and chemical methods is included. C. C. YOUNG

Archiv für Rassen- u. Gesellschafts-Biologie, einschliesslich Rassen- u. Gesellschafts-Hygiene—*v. 21, Heft 3. München: Lehmanns Verlag,* 1929. Price, M. 6.

This well known German journal under the able editorship of Dr. A. Ploetz and Dr. Fritz Lenz of Munich with a group of collaborators is the organ of the German Society of Racial Hygiene. It concerns itself with problems of human heredity, eugenics, and euthenics, with the emphasis upon the biological approach to the various phases of the subject. The issue on hand contains Dr. Lenz's critical discussion of Burgendörfer's statistical analysis of the decline of the birth rate in Germany, an article by Dr. H. H. Laughlin on the history of legal sterilization of defectives in the United States, a statistical study by Dr. Gschwendtner, by the questionnaire method, of the motives favoring and hindering child bearing in Austria, and a study of musical talent as shown by use of the violin in sixteen peasant families. There are also news items and critical reviews of current literature. C. A. KOFOID

At Home Among the Atoms. *A First Volume of Candid Chemistry—By James Kendall, Sc.D., F.R.S. New York: Century,* 1929. 318 pp. Price, $3.00.

Here is a popular book which develops, with essentially the same system and sequence as ordinarily used in good texts, the field covered by an introductory course in the science of chemistry. Certainly it would not serve for a text for such a course, and the author makes it very clear that the book "has not been written for the scientific expert," and is "not even intended to serve . . . as a text book for beginning students." It is far too highly diluted for such a purpose, though the diluent is seldom extraneous.

The book is written for that part of the public whose desire is "not merely to know but also to understand," and it is the sincere feeling of the reviewer

that a comprehension of this book will furnish a fundamental understanding of chemistry as a science. One should not expect it to bring a full grasp of that science. Non-chemists should not expect to learn chemistry through its perusal, though it may inspire many to read further. Chemists should be able to spend a very enjoyable, and in many cases, profitable, evening with the book, as it is delightfully written, and one cannot but feel that one's enjoyment in reading it was fully shared by the author in writing it. This personal interest on the part of the author in his presentation has resulted in a greater precision in presenting many phases than one finds in many popular treatments.

ALLEN E. STEARN

The History of a Crime Against the Food Law. *The Amazing Story of the National Food and Drugs Law Intended to Protect the Health of the People. Perverted to Protect Adulteration of Foods and Drugs—By Harvey W. Wiley, M.D. Washington: Harvey W. Wiley,* 1929. 413 pp. Price, $2.00.

The story of the fight which has been waged for the protection of the public against adulterated and unfit foodstuffs is not a pleasant one. Politics has often played a larger part than a consideration of the welfare of the public. While some adulterations have only a commercial and not a public health interest, none the less the people should be protected against them.

No single person has played a larger part in the struggle for pure foods than the author of this book. He has been in, and a part of, the struggle from the beginning. His so-called "Poison Squad" attracted wide attention, and was the means of making many people think for the first time of the quality of the foods they were buying and eating.

In the volume before us, Dr. Wiley has given a chronological account of what has taken place in governmental circles and shown up the various influences which have played so large a part in defeating the administration of the Food and Drugs Law. The book is thoroughly documented, and contains many quotations of hearings, reports, resolutions, etc. Fortunately there have always been a certain number of persons fighting on the right side, but they were often handicapped by official inaction or opposition.

The book tells the story of which no American has reason to be proud. We believe that Dr. Wiley deserves great credit for collecting in a convenient form the mass of material scattered through various governmental documents. The importance of the study of nutrition and foods is now recognized as never before. The struggle for pure foods and proper foods is by no means over. Sophistication of all kinds is still practiced. Adulterants, coloring matter, bleaching processes, etc., are still tremendously used, and probably will be until human nature becomes regenerated. The desire for gain still overshadows often the welfare of the people.

The printing and make-up of the book are good. A number of illustrations are given. As a believer in the historical method of teaching we commend this book to all students of nutrition, and to the medical profession in general, as well as to the public.

M. P. RAVENEL

You and the Doctor—*By John B. Hawes, 2d. Boston: Houghton, Mifflin,* 1929. 181 pp. Price, $2.00.

This book by Dr. Hawes has "punch" to it, holds the interest, and, best of all, offers advice that is sound and easily understood by the layman.

It takes courage to begin a book as Dr. Hawes has done by a discussion of

medical ethics. The risk is run of irritating both doctor and patient. The author by his sincere handling puts the subject on the plane of common sense. What might be termed the specialist's point of view is kept for the most part pretty well in the background. His touchstone is: The patient comes first.

A chapter on medical economics takes up the subjects of cost of sickness; physicians' fees; how to choose a good physician; and treatment by a specialist. The handling is frank—quite the best we have seen. The part dealing with specialists' fees may seem unconvincing to some.

Following these more general matters the author gets down to a discussion of symptoms, what they may mean and what to do in case you have any of them. Headache; pain in chest and abdomen; backache; tumors; hemorrhage; coughs and colds; rheumatism and neuritis; constipation; "kidney trouble"; are treated of in language which the intelligent layman can readily understand. A very good chapter is that on "Nerves"; another is the one on "Vacations." The "Family Medicine Chest" that Dr. Hawes allows has somewhat more in it than some physicians would agree to, perhaps, but a good reason is given for the inclusion of the various articles.

The keynote of this book may be said to be the frankness and honesty which the author emphasizes in the last chapter—"Doctor and Patient"—as being essential in the relations of a patient to his physician.

MERRILL E. CHAMPION

The Modern Baby Book and Child Development Record—*By John E. Anderson and Florence L. Goodenough. New York: Norton,* 1929. 398 pp. Price, $5.00.

The publishers say: "Here is a modern baby book combining the sentimental features of the conventional baby book and scientific records. The records are easy to keep and will enable you to compare your child's development with the 'average' child."

These statements are comparatively true. This is a big book, with much space for data and tests and answers to questions for ages up to 16 years, which will show a child's comparative development, and be interesting to the mother, and perhaps, later, to the subject. At the same time she is making comparisons with the author's ideas of a normal child, and so gauging her own child's progress.

However, it is *not* too easy to keep up and the effort required is possessed by many, but not all of even intelligent modern mothers.

The reviewer cordially recommends the book. W. D. LUDLUM

The Prevention of Human Tuberculosis of Bovine Origin—*By William G. Savage, M.D. (London), D.P.H. London: Macmillan,* 1929. 195 pp. Price, $4.25.

Bovine tuberculosis is a more serious, more unyielding problem in England than it is in the United States. An authentic picture of the extent of human tuberculosis of bovine origin is wanting, but the author has taken pains to examine many studies made in various places, as well as much circumstantial evidence, which leads him to assume that in Great Britain about 1 per cent of the respiratory, and 23 per cent of non-respiratory tuberculosis deaths in each year are of bovine origin. As to the number of bovine infections which do not terminate fatally, he dares not venture a guess.

The American method of dealing with bovine tuberculosis is not applicable in England, chiefly for the reason that in the United States positive reactors among cows range from 3 to 5 per cent, while in England the percentage is about ten times as great. To slaughter some

40 per cent of the dairy cattle would cause a milk famine and necessitate enormous compensation payments.

The possibility of eradicating the disease through some method of vaccination, as, for example, by the use of BCG, is full of interest, but at present holds out scant hope. There is an excellent description of Calmette's efforts to immunize cattle against tuberculosis. The method advocated by Bang, of Copenhagen, designed to bring about the rearing of herds free from tuberculosis, has apparently not resulted in the success hoped for. The practice of "designating" or certifying certain milks is a delusion. Pasteurization, while theoretically efficient, often fails lamentably in practice, as evidence of which he cites the experience of Montreal's recent epidemic of enteric fever, which was traced to milk supposed to have been pasteurized. The chief reason, however, why he is unwilling to rely on pasteurization is that its adoption would set back the steps now being taken to produce a cleaner milk, which seems reasonable in view of the wide extent of bovine tuberculosis and the haphazard, uncontrollable organization of the dairy business in England. Reliance on pasteurization alone is, to the author, a confession of failure.

The measures he advocates are based on the broad viewpoint that the problem must be solved by attacking bovine tuberculosis as a preventable disease and the campaign must be similar to that for the eradication of human tuberculosis. He recommends, in brief, the building up of the resistance of cattle by improving their environment, notoriously bad in England, and the prevention of infection from cow to cow by segregation and the immediate separation of newborn calves from their dams. He would not neglect the usual measures of keeping a vigilant eye on the milk supply as it reaches the consumer or the heat treatment of milk. That involves carefully coördinated administrative machinery, making possible frequent veterinary and bacteriological inspections, the compulsory notification of all cases, expert supervision of cattle that have general tuberculosis but no disease of the udder. If agriculturists are not prepared to coöperate actively to reduce the incidence of bovine tuberculosis, state aid in the form of indemnities and the cost of supervision will not be of sufficient moment to warrant the disturbance of existing practice, for only a slight reduction of human tuberculosis will result. Should dairymen obstruct the radical measures recommended, it will be better for the sanitarian to face the problem of preventing human infection in his own way—by controlling the milk supply as far as possible and establishing an adequate system of pasteurization—a confession of failure but the second best procedure.

The book is replete with tables and reports of research, technical information concerning the bacteriology and biology of tuberculosis and administrative procedures. The argumentative logic seems well knit together, though presumably the conclusions will not be generally accepted by American sanitarians as applicable to this country.

H. E. KLEINSCHMIDT

Hygiene of the Mouth and Teeth—*By Thaddeus P. Hyatt, D.D.S., F.A.C.D. Brooklyn: Brooklyn Dental Publishing Co.,* 1929. 64 pp. Price, $1.00.

This book of approximately 65 pages is written by the Assistant Medical Director of the Metropolitan Life Insurance Company. It is intended for general reading, and contains much useful advice on the care of the mouth and teeth, a subject which is constantly receiving more and more attention.

M. P. RAVENEL

Training Schools for Delinquent Girls—*By Margaret Reeves. New York: Russell Sage Foundation,* 1929. 455 pp. Price, $3.50.

It would be hazardous to estimate the value of this book in the field of delinquency. Certain values seem fairly clear. It gives us a perspective on the field as we have never had it before. It will provide legislators, boards and staffs with a source of information that will leave no excuse for continuing to create a permanent social liability while temporarily safeguarding society. It will provide suggestive material and analogies for those in other types of institution and other fields of social work.

The defects of this treatise are largely the defects of the field itself. One gets the feeling, despite obvious contrary attempts of the author, that the institution for delinquent girls is by itself. Perhaps this is due to the fact that the institutional life is not part of a larger program which is laid down before the girl reaches the institution, and of which the institution might be but rarely is a step in treatment. Usually the purpose in institutionalization is unburdening society of a problem, and it is left to the school to work out the plan after the first step in treatment is taken. To quote the author: "Ideally this study should have begun when the girl first entered the institution."

We raise the question—why not begin it before, so as to see if the institution is a proper step in treatment? Again the possibilities of an institution of this sort for conducting extramural work with non-institutional cases are not revealed. Surely the high grade staff advised would be of great value to those not requiring a new home. This all seems to relate to the fact that seldom is a treatment plan thought out and recorded.

Even in the suggestions for record keeping no provision is made for this most important step. If the record is thought of as the record of examinations, leading to a plan of treatment, we need not worry about its value as a check on the worker. There is also no indication of the mechanism whereby these various social, medical, and psychological examinations may be integrated.

Experience has shown that mere recording is not enough; some such instrument as the case conference is essential. This lack of integration is evident in the small extent to which the psychologist is brought into the school plan, whereas one of his greatest possibilities of contribution lies here.

The reviewer being primarily interested in the mental hygiene aspects of the book is hardly qualified to present a critical review of other features. The historical background is valuable in showing the evolution of the treatment of juvenile delinquents. The idea of constructing the institution around its functions is appealing. The chapter on psychological and psychiatric work is well said with the reservations above stated. One might take exception to the thought that these girls need to forget their sex experiences. The possibilities of making these experiences a value cannot be forgotten.

If one is looking for the trick which the schools use to turn the delinquent into an adjusted girl, he is bound to be disappointed. He reads in this book of things that might apply to any school or any home. If he is wise he might deduct from this the fact that the delinquent girl is not a different person requiring a different trick of education, but one requiring more careful attention to the principles of rearing that are applicable to any child. In the absence of a qualified home, school or society, the institution attempts to fill in the need. GEORGE S. STEVENSON

The Most Nearly Perfect Food—*By S. J. Crumbine, M.D., and James A. Tobey, Dr.P.H. Baltimore: Williams & Wilkins,* 1929. 292 pp. Price, $2.50.

The authors have prepared an interesting story of milk which is well printed and contains some 22 selected illustrations. While designed primarily for the lay reader, the book contains so many facts regarding the food value and the production and handling of milk and milk products of various kinds that it should prove useful for teachers and students of home economics, agriculture, dairy science, and public health.

Separate chapters deal with a balanced diet, a historical sketch regarding the use of milk, milk and the promotion of health, how to get clean and safe milk, and the use of milk and milk products. The reviewer is inclined to agree with the authors who state that, from our present knowledge, the main objective in milk production and control is the production of a maximum amount of milk from healthy non-reacting tuberculin tested cows under approved sanitary conditions, all of which, with the possible exception of certified milk, should be pasteurized. It should then be quickly cooled to from 45° to 50° F. and bottled in sterile containers. "Such milk is both wholesome and safe."

IRA V. HISCOCK

Bacteriology of the Home—*By Ava L. Johnson. Peoria: Manual Arts Press,* 1929. 167 pp. Price, $2.25.

This book aims to present to students of home economics and to housewives those facts about bacteriology which can be put to practical use in the home. Such subjects as washing the hands, washing dishes, cleaning the house, refrigeration, canning of foods, and the care of milk, are discussed in detail. The text is made more attractive by many photographs of agar plates showing cultures taken from washed and unwashed hands, and foods and utensils under various conditions. To the casual observer these are quite convincing pictures, though only quantity of growth is shown, without any interpretation of the significance of the organisms. The book includes a laboratory guide which gives the procedure for the production of cultures of this type.

The author popularizes the axiom, "There are bacteria everywhere," and seems to dwell unnecessarily on the obvious. Little differentiation is made between pathogens and non-pathogens. The truth of such a statement as the following might be questioned, "Anything boiled in water twenty minutes is sterile." It seems outside the province of this book to voice an opinion on vaccination and the preparation of biologic products. Complete ignorance of the subject is demonstrated conclusively in the text.

GRACE ELDERING

Human Nature and Management: *The Application of Psychology to Executive Leadership—By Ordway Tead. New York: McGraw-Hill,* 1929. 312 pp. Price, $3.50.

It should surprise no one if, after studying Mr. Tead's thorough-going treatise on the application of modern psychology to executive leadership, the executive tyro were to spend a few minutes in the outside office walking on his hands and brushing up on his defense mechanisms. For this eminently sensible specialist in the problems of personnel administration has given the beginner in the intricacies of human management a rather large order. If, having absorbed the theory of it, he succeeds in the application of it, he is a better man than a raft of executives old and new who stand very much in need of just the sort of practical advice in which this book abounds.

In his *Mansions of Philosophy,* Dr.

Will Durant suggests that some of his readers had better dispense with the opening chapters as being a bit too technical for the general run of laymen. The author of *Human Nature and Management* warns the reader not to become discouraged early in the book; but expects him to find his way through the first 10 chapters, dealing in a clear and illuminating manner with the intricacies of personality psychology. For his patience in reading these initial chapters, the layman will find a rich reward in the succeeding discussion of the practical applications which take the form of methods and procedures adjudged psychologically sound in the management of human beings.

Mr. Tead appears reassuringly antirobot. He is at his best in dealing with the problems of desirable group action. His conception of the new discipline is convincing: "that orderly conduct of affairs by the members of an organization who adhere to its necessary regulations because they desire to coöperate harmoniously in forwarding the ends which the group has in view and willingly recognize that to do this their own wishes must be brought into reasonable unison with the requirements of the group in action." In the presence of such wholesome reasoning, our faith in the blessings of American democracy gets a substantial boost. Yes, we are doing better and we will do better still, no doubt, when we have our lesson from Mr. Tead and put his wise precepts into everyday practice.

MINOTT A. OSBORN

The Mind at Mischief (*Tricks and Deceptions of the Subconscious and How to Cope with Them*)—*By William S. Sadler, M.D., F.A.C.S. New York: Funk and Wagnalls,* 1929. 400 pp. Price, $4.00.

In the language of the street, this book is "just another one of those things." In the language of science, it constitutes just another portion of psychiatric hash—and not very good hash at that. The author has drawn upon a bewildering variety of sources for the description of the various conditions but he does so without any rational classification of the various concepts and points of view involved. The result is that the non-technical reader surely must feel confused at the mental gymnastics required of him, if he is to extract from this book any orderly, comprehensible idea of what it is all about.

As far as those parts of the book are concerned which represent Dr. Sadler's own thinking, there is little to recommend. His premises often are sketchy, his deductions frequently weird, and his thinking is shallow. *The Mind at Mischief* is just about the sort of effusion one has come to expect from enthusiastic and probably well-meaning authors whose training in psychiatry is negligible or, at best, meager.

In the exhaustive list of qualifications attributed to the author on the title page, there are none that would indicate he has had the privilege of receiving competent psychiatric instruction, and when one notes that the other books by the same Jack-of-all-trades author range from discussions of "Blood Pressure and Nerves" to "Constipation," "How to Feed the Baby," "The Elements of Pep," etc., one is perhaps justified in drawing conclusions as to his competency in any one of these fields.

"The Psychologist's Introduction" by Robert H. Gault, Ph.D., Professor of Psychology at Northwestern University, and "The Neurologist's Introduction" by Meyer Solomon, M.D., Associate in Neurology at Northwestern University Medical School, likewise contribute little to the usefulness of this volume.

In general, the reviewer feels that the book is of no particular importance.

GEORGE K. PRATT

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Cincinnati, O.—Municipal activities in this city for 1928 are recorded in a carefully prepared report of 198 pages, of which 8 are devoted to the Board of Health. A diphtheria prevention campaign was launched by the Health Department under the auspices of the Academy of Medicine, and over 25,000 children under 10 years of age went to their family physician or to a clinic for the toxin-antitoxin treatments. Next in importance was the summer round-up of preschool age children. This was the second year of an extensive program of preparing children under the age of 5 for their first year in school.

A health center houses a diagnostic chest clinic, primarily for the prevention of tuberculosis, a venereal disease clinic, an adult dental service, a heart clinic, a children's division, and the administrative offices of the Public Health Nursing Bureau. During the year a full-time medical service was developed.

A permit system inaugurated for all food establishments in 1926 is said to have resulted in marked improvement in shop sanitation. A total of 6,529 applications for permits were filed, at a service charge of $2.00 for each inspection. Seventeen permits were revoked from establishments which failed to maintain proper sanitary standards. Effective this year, it was also necessary for the milk collectors to obtain a permit from the Health Department in order to deliver milk for use in the city.

Coincident with the general pasteurization which became effective in 1915, there has been a marked decline in the number of cases of typhoid fever, diphtheria, tuberculosis, and other communicable diseases that are milk-borne. Paralleling this, we see a marked decrease in infant mortality, and especially in the deaths from gastroenteritis among children under the age of 2.

Each public health nurse carries out a generalized program in her district. By this means, "the family is the unit with which the nurse works rather than the individual who may present a special condition. This procedure results in an elasticity of service which insures health supervision for every member of the family." There were 41,868 home nursing visits made in 1928.

Knoxville, Tenn.—The 1928 report estimates the population of this city as 105,400, and records a general death rate of 14.09 (12.8 for whites and 20.7 for colored), the resident rate being 12.9. A birth rate of 22.8 and an infant mortality rate of 87 are also noted. The leading causes of death are pneumonia, heart disease, tuberculosis, nephritis and congenital and early infancy conditions.

Milk supervision is exercised in accordance with the Standard Milk Ordinance which was adopted in 1924 and has stimulated marked improvement in conditions. Some 506 dairies with 6,569 cows produced an average of 11,059 gallons of milk daily, or nearly 0.9 pint per capita. There were 1,364 dairy inspections. Approximately 51 per cent of the milk supply is pasteurized.

Progress is noted in generalized nursing service, a total of 75,829 home visits having been made last year. There were 10,778 new cases admitted and 10,502 cases discharged. Of the new cases, 1,439 were under 1 year of age and 1,178 were 1 to 6 years of age, while 1,254 were 6 to 16 years of age and 6,917 were over 16 years. Some 2,800 visits were made to 436 well baby conferences.

This mimeographed report of 89

pages abounds in statistical tables, charts, and graphs, which add materially to the interest and value of the annual record of accomplishment.

Rhode Island Tuberculosis Survey—A constructive survey of the tuberculosis work in 15 towns of the state has been made by the Superintendent of the State Sanatorium. These are towns in which tuberculosis clinics have been conducted by the medical staff of the sanatorium for periods varying from 2 to 7 years.

According to standards of the *Appraisal Form for City Health Work,* reporting averages only half of the standard of 2 cases (all forms) annually per death. One town receives full credit. The standard of 50 field nursing visits to homes of tuberculosis cases is reached by 7 of the 15 towns, while in 3 towns fully 20 per cent of the home visits were made to ex-sanatorium cases as is recommended.

The clinics in these towns are almost entirely diagnostic in nature, the patients being sent back to their physicians for treatment. In some of the towns hospitalization is high and unusually prompt. There were 1,190 individuals who made 1,543 clinic visits during the year.

Hospitalization at the State Sanatorium, Providence City Hospital, Hills' Grove Hospital and the Crawford Allen Hospital during 1928 amounted to 164,101 hospital days against an Appraisal Form standard of 123,750. This figure is exclusive of preventorium. Newport has a summer camp for children and a pasteurized milk supply.

Seattle, Wash.—This city with an estimated population of 383,200 reports a birth rate of 13.03, a death rate of 10.4 and an infant mortality rate of 42 for the year 1928. Physicians in attendance at child welfare clinics for the purpose of making examinations and giving advice are selected children's specialists working under the management of the Seattle Pediatric Society in coöperation with the department of health. There were only 4 deaths from diphtheria with none from scarlet fever or smallpox during the year. The report recommends that necessary legislation be enacted to make compulsory the pasteurization of all of the city's milk supply with the exception of the certified product.

New York Tuberculosis Clinics—The 20th annual report of the Association of Tuberculosis Clinics, for 1928, shows that this voluntary organization includes in its membership 27 clinics functioning either under municipal or private auspices. Their activities are confined to clinic and home work among the tuberculous and the exposed families of these patients.

In 1927, 40 per cent of the patients came to clinics in the first stage of the disease, 42 per cent in the second stage, and 18 per cent in the third stage. In about two-thirds of the cases then there was already extensive involvement of one lung or disease of both lungs. Efforts are made to examine all members of households of tuberculosis patients and to maintain a continual check on the situation. These clinics are coöperating in a study of the effect of Calmette-Guérin vaccine on infants in actual contact with tuberculosis.

Winnipeg, Man.—The city assessor's figures show a population in 1928 of 202,377, while the annual report of the medical health officer indicates that there were 1,806 deaths in the year, or a rate of 8.9. An infant mortality rate of 63.46 is recorded. An influenza outbreak in December is said to have raised this rate from an average for 11 months of under 60. A birth rate of 22.1 is

only slightly lower than that for the previous year, while the marriage rate of 13.9 is higher (12.27 in 1927).

An excellent financial statement is presented in two parts, one covering the control and prevention of disease services, the other, refuse collection and disposal and street cleaning services. The net per capita expenditure under the first heading was 59.1 cents, being about one-third as large as that for the other items.

The outstanding event of the year from a health standpoint is said to be an outbreak of acute anterior poliomyelitis which occurred during the summer and early autumn. The report contains an interesting analysis of the outbreak with an account of measures carried out. The type, particularly in the early cases, was severe and the percentage of fatalities high. Of 225 city cases, 100 were among females. Ages varied from 2½ to 15 years. When a case was isolated in a home, children who resided on the premises were quarantined. Food handlers were quarantined unless arrangements were made for their change of address when the individual was prohibited from engaging in such occupation for a period of 2 weeks. Teachers, or persons having to do with children when exposed to a case, were quarantined for a similar period. Concurrent disinfection was recommended and at the termination of a case, thorough cleansing, sunning and airing of material in the sick room with soap and warm water were instituted. It is believed that the administration of serum early in the attack was of definite value.

Fort Worth, Tex.—The annual mimeographed report of the department of public health for the year ending September 30, 1929, shows that of the 2,929 births, 35 per cent occurred in hospitals. There were 1,941 deaths from all causes, of which 369 were among Negroes and 91 among Mexicans. Of these deaths, 134 occurred among infants under 1 month and 106 among infants of 1 month to 1 year of age. Communicable diseases are recorded according to the number of cases, the number of health department visits, the number of contacts, and the number hospitalized.

Twenty boarding homes were granted permits during the year and 906 children were placed in licensed boarding homes. A total of 1,162 birth certificates were delivered by nurses, while in 624 cases the homes could not be located for this purpose. Of the 9,501 persons who attended the health centers, 2,893 were infants and 3,495 were preschool children.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

A History of Malaria—The probability of continued freedom from malaria in the north is contrasted with the persistent danger of a recrudescence in the south. All the factors are closely related to the agricultural development of the country.

BARBER, M. A. The History of Malaria in the United States. Pub. Health Rep., 44, 43: 2575 (Oct. 25), 1929.

A County Health Survey—A house-to-house survey of an Ohio county to determine the extent of health protection and the health needs revealed some arresting conditions. More than 3 per cent of the people had had smallpox; 80 per cent of the school children had not been vaccinated; diphtheria immunization was negligible. The work accomplished is recounted.

BARNES, M. E. A County-Wide Sanitary and Health Survey. Pub. Health Rep., 44, 39: 2315 (Sept. 27), 1929.

Granite Dusts—By a series of studies it was determined that a velocity of 1,500 feet per minute in dust removal hoods would keep down the dustiness of the air breathed by the operative below 10 million particles per cu. ft. of air, the safe limit. This standard places no hardship upon the granite-cutting employer.

BLOOMFIELD, J. J. A Study of the Efficiency of Dust-Removal Systems in Granite-Cutting Plants. Pub. Health Rep., 44, 42: 2505 (Oct. 18), 1929.

Irradiated Foods—All health workers will want the truth about irradiated foods, some of which are so widely advertised. Undoubtedly they will be asked about them by curious people. The answer will be found in this article, a chapter from the authors' book which is about to be published.

BLUNT, K., and COWAN, R. Irradiated Foods and Irradiated Ergosterol. J. A. M. A., 93, 17: 1301 (Oct. 26), 1929.

Diet and Dental Caries—Since diets high in mineral and vitamin content have been found to arrest dental caries within 2 months, the authors suggest that active caries should be viewed as indicative of nutritional deficiencies.

BOYD, J. D., *et al.* Dietary Control of Dental Caries. Am. J. Dis. Child., 38, 4: 721 (Oct.), 1929.

Chautauqua Health Talks—How health talks were prepared and delivered in Chautauqua and some of the more tangible results. From this beginning great accomplishments are possible.

CALVER, H. N. Tent-Speaking for Health. Quarterly Bull. (Millbank Mem. Fund), 7, 4: 77 (Oct.), 1929.

Joint Tuberculosis Project—How the Providence nursing association and tuberculosis league joined to tackle the problem of providing an adequate tuberculosis nursing service is interestingly told. The A. P. H. A. *Appraisal Form* is used to check results.

CLARKE, F. C. Combining Against Tuberculosis. Pub. Health Nurse, 21, 10: 522 (Oct.), 1929.

Rural School Ventilation—The generally unsatisfactory condition of the heating systems of the rural schools that were studied is described. Absenteeism due to respiratory illnesses was twice as high as the rates in Syracuse and four times that in New York schools.

DUFFIELD, T. J. A Study of Rural School Ventilation. Pub. Health Rep., 44, 40: 2383 (Oct. 4), 1929.

Heart Disease—Heart disease is a disease of early life; 75 per cent of all cases develop in children under 10. Heart disease is third highest in causes of death among children. These are some of the statements in this non-technical discussion of heart disease as a public health problem.

CLARK, T. Heart Disease as a Public Health Problem. Pub. Health Rep., 44, 41: 2463 (Oct. 11), 1929.

Health Examinations—A department store president comes out strong for health examinations. He tells physicians to organize for efficient health service, but neglects to point out just how the patients are to be induced to pay for being kept well.

FILENE, E. A. Autocare versus Medical Care. J. A. M. A., 93, 16: 1247 (Oct. 19), 1929.

Adaptability of the Body—Notes on the physical examinations of the participants in one of the notorious transcontinental " bunion derbies " prove an interesting commentary on the amount of punishment the human body can absorb.

GORDON, B., and BAKER, J. C. Observations on the Apparent Adaptability of the Body to Infections, Unusual Hardships, Changing Environment and Prolonged Strenuous Exertion. Am. J. M. Sc., 178, 1: 1 (July), 1929.

Incomplete Reporting of Births—The possibility of correcting reported birth rates as the author has done for the city of Baltimore, suggests the need for adjusting all birth statistics for the years prior to complete birth registration. This proposal would make less startling many convincing graphs showing the remarkable savings in infant lives by this and that child health activity.

HEDRICH, A. W. Correction of Birth Rates for Incomplete Reporting. Am. J. Hyg., 10, 2: 435 (Sept.), 1929.

Computing Epidemic Cycles—Two methods of obtaining epidemic cycles are discussed, one based on the assumption that the seasonal component varies, the other that it is constant. The author's opinion that the simpler method is satisfactory will be good news to struggling tyro statisticians.

HARMON, C. E. A Comparison of Two Methods of Obtaining Epidemic Cycles. J. Prev. Med., 3, 5: 405 (Sept.), 1929.

Is Immunity Transmitted to Babies?—The author studies the incidence of reportable diseases by months throughout infancy; presents his findings; leaves the answer to the reader. A stimulating and brief paper.

KNOWLTON, M. Do Mothers Transmit Immunity to Their Children? J. Prev. Med., 3, 5: 385 (Sept.), 1929.

Tuberculosis Epidemiology—Available figures of tuberculosis mortality in comparable form are studied in this paper. Among the numerous conclusions is the interesting one that should the present trend be continued, the tuberculosis death rate should be 10 per 100,000 in 1970.

LEE, W. W. The Epidemiology of Tuberculosis, Past and Present. Am. Rev. Tuberc., 20, 3: 368 (Sept.), 1929.

Cancer Studies—Many interesting conclusions are afforded by a study of the nativity of cancer patients in Massachusetts. Among them are these: Foreign born have higher rates than natives in cancer of the buccal cavity and stomach; Irish and Italians show higher rates in Boston than in their own countries.

LOMBARD, H. L., and DOERING, C. R. Cancer Studies in Massachusetts. J. Prev. Med., 3, 5: 343 (Sept.), 1929.

Metal Poisoning—The possibilities of poisoning by the ingestion of small amounts of lead, arsenic, etc., are discussed in detail.

MYERS, C. N., and THRONE, B. Health Hazards from the Ingestion of Small Amounts of Metals. New York State J. Med., 29, 20: 1258 (Oct. 15), 1929.

British Dairy Supervision—A paper on the sanitation of milk production in which the word "pasteurization" did not appear would be a rarity in the United States. How cows shall be kept and inspected and how milk is to be handled are discussed at length; but there is no word about pasteurization.

RABAGLIATI, D. S. The Milk and Dairies Order, 1926. Pub. Health, 42, 12: 408 (Sept.), 1929.

Tropical Medicine—A bird's-eye view of the problems of tropical medicine and the world-wide organization built to meet them.

REED, A. C. Tropical Medicine. Sci. Monthly, p. 458 (Nov.), 1929.

Industrial Health—The first ten of a series of health practice pamphlets to be issued by the Industrial Health Division of the National Safety Council have been published. They deal with the following subjects: chromium, lead, physical examinations, health supervision, eye hazards, carbon monoxide, wounds, skin affections. Health workers who have industrial hygiene problems to meet will find this series invaluable.

SAPPINGTON, C. O. Health Practice Pamphlets 1–10. National Safety Council, Chicago, Ill.

Organisms in Malignant Tumors—Reporting the findings of many years of study of an organism recovered from malignant tumors, never found in benign growths. Although the presentation is highly technical and no conclusions are attempted, health workers will be interested, if only because they will gain anew a wholesome respect for the newer conceptions of bacteriology.

STEARN, E. W., *et al.* The Ontogeny of an Organism Isolated from Malignant Tumors. J. Bact., 18, 4: 227 (Oct.), 1929.

Reducing Diets—The rudiments of weight reduction through diet are briefly presented. Specimen diets are suggested and tables of vegetables given.

TERRY, A. H. The Reducing Diet. New York State J. Med., 29, 19: 1192 (Oct. 1), 1929.

Baby Clinic Practice—In this British clinic a room with an out-door sheltered court is set aside where mothers may bring their children during the nursing period. Here the attendants can discover errors in breast feeding technic. Seemingly a sensible suggestion for babies needing such observation.

WALLER, H. K. Avoiding Failures at Infant Clinics, Med. Off., 41, 24: 263 (June 15), 1929.

Living in the Tropics—Life in the tropics will become more comfortable and safe for the white man but acclimatization, in its full and literal sense, will remain impossible. This is the interesting conclusion of this treatise, worth reading by all who face the problem of fighting heat.

WARD, R. D. The Acclimatization of the White Race in the Tropics. New England J. Med., 201, 13: 617 (Sept. 26), 1929.

Maternity Nursing—Worth-while illustrations with their detailed captions add greatly to the very practical information contained in the article mostly about the care of new-born babies. It is a fine example of the value of good illustrations intelligently used. The pictures are from the author's excellent new book *Nurses Handbook of Obstetrics*.

ZABRISKIE, L. E. Maternity Nursing in Hospital and Home. Am. J. Nurs., 29, 10: 1157 (Oct.), 1929.

NEWS FROM THE FIELD

DEVELOPMENT OF SCHOOL HYGIENE

BUENOS Aires, Argentina, was the first city in South America to start school-hygiene work. This work was introduced in Buenos Aires in 1886. At present the school medical board employs a large number of physicians, several dental inspectors, a large staff of health visitors, and one psychiatrist.

There are various kinds of clinics for the teachers and school children, such as eye clinics, ear, nose, and throat clinics, dental clinics, x-ray clinics, clinics for tuberculous children, and clinics for backward children. The school authorities have also established summer colonies for underfed children; school lunches are also provided.

In Rio de Janeiro, Brazil, the school medical service is only a few years old. A large number of school physicians, dentists, and nurses are employed. The school nurses assist the doctors during the examinations of the children and visit the children at their homes. There is a movement for the establishment of clinics for the free treatment of school children.

In Chile, as a result of a reorganization in 1928, a school medical service has been established in several cities.

In Santiago the school medical service consists of physical examinations of the school children and of clinical treatments. The work is carried on by physicians, assistant physicians, and nurses. There are in Santiago clinics for the diseases of the eye, ear, nose and throat, and a psychological laboratory. At the end of 1928 the government entrusted the school medical service to the care of the Ministry of Hygiene and Social Welfare. This permits the extension of the work to every part of the country where a public health officer is located.

The school medical service of Uruguay seems to be limited to the capital, Montevideo. It was established in 1908, but it has been extensively developed only in the last decade. There is now a large number of school physicians and nurses. School clinics have been established for the treatment of diseases of the eye, ear, nose, and throat, skin, and lungs; there is also a nutrition clinic. Several open-air schools and vacation camps are maintained by the Government, and a school-lunch system is maintained by a private society.—*Boletin del Institute Internacional Americano de Proteccion a la Infancia*, July, 1929.

INTERNATIONAL CONGRESS OF AMERICAN UNIVERSITIES

TWENTY-ONE nations of the New World will be represented in Havana on February 15, 1930, when the First International Congress of American Universities convenes. Fifteen important educational points are to be discussed, and these questions are now in preparation.

The fundamental aim of the Congress is to introduce international subjects into curriculums for the purpose of creating confraternity in student circles.

Dr. Octavio Averhoff, dean of the University of Havana, announced that two of the prominent guests of the congress will be Dr. Ray Lyman Wilbur, Secretary of the Interior and President of Leland Stanford University; and Dr. Charles Mayo. Both of these men will receive the degree *honoris causis* of the University of Havana during their stay.

THE PRESCHOOL CHILD

AN interesting and attractive booklet for the mother of the child under 6 years of age has been written by Dr. Richard M. Smith, Assistant Professor of Child Hygiene at Harvard Medical School. The title of the booklet is *Between Two Years and Six.*

Advice is given to mothers about the care of the child's body in health and sickness, and the child's mind as well. Space is provided for recording the child's development from year to year for the benefit of the mother and the physician who may see the child from time to time. This booklet is offered free to health officers and social agencies by the Life Conservation Service of the John Hancock Mutual Life Insurance Company of Boston, Mass.

PHYSICIANS IN CONGRESS

WHEN the Seventy-first Congress of the United States convenes in December there will be 7 physicians in it. At the last Congress there were 8 and the Sixty-ninth Congress had only 6.

The newest physician congressman is Senator Henry D. Hatfield of West Virginia; the oldest in the point of service is Representative John W. Summers of Washington.

The other physicians in this Congress are: Dr. Royal S. Copeland and Dr. William I. Sirovich of New York, Dr. J. Howard Swick of Pennsylvania, Dr. Edward M. Irwin of Illinois and Dr. Frank P. Bohn of Michigan.

STUDY OF BIRTHS

TRIPLETS are born about once in every 10,000 births.

Twins occur about once in 98 births.

These facts are disclosed in a study of births in non-municipal hospitals of the United Hospital Fund of New York, made by the Fund in maternity hospitals of the group and the maternity services of its general hospitals last year. Thirteen hospitals reported a total of 19,473 babies born last year. During the year there were only 2 instances of triplets, and 201 of twins. There were no quadruplets.

NEW OFFICERS OF DELTA OMEGA

AT the annual meeting of Delta Omega, the honorary public health society, held in Minneapolis on October 2, 1929, during the convention of the American Public Health Association, C. C. Young, Ph.D., D.P.H., Director of the Bureau of Laboratories of the Michigan State Department of Health, was elected national president. John A. Ferrell, M.D., Dr.P.H., of the Rockefeller Foundation of New York, was elected national vice-president, and James A. Tobey, Dr.P.H., of New York, was reëlected national secretary-treasurer.

SIGHT TEST FOR SAILORS

THE U. S. Public Health Service, for over 50 years, has conducted examinations and reëxaminations of masters, mates and pilots of American vessels, to determine visual and color perceptions. This has been done at the request of the U. S. Steamboat Inspection Service.

Lately, however, a more rigid test has been needed, and the commonly applied test with yarns and lanterns seems inadequate. After an intensive study, the Surgeon General of the U. S. Public Health Service has decided to introduce a " foolproof " method of testing vision, by using the colored plates test of the kind of which the Stilling's method is representative. This test has been adopted by the U. S. Navy and enables the medical officers to determine easily and with much precision whether an applicant has defective color sense, because, if so, the candidate is totally unable to perceive the figures that appear

upon the dotted chromatic plates. These are easily discernible to a person of normal color vision.

To prevent injustice to licensed pilots, masters and mates, the old test will be used when they are reëxamined.

UNIVERSITY COURSE IN ACCIDENT PREVENTION

AT the 18th Annual Safety Congress held in Chicago, September 30 to October 4, it was revealed that 97,000 persons were killed by accident in the United States during the last year—the greatest total of such casualties in the history of the country. At the same time the records of the New York State Department of Labor show that during the first 7 months of 1929 in the metropolitan district alone 10,000 more accidents were reported than during the corresponding period of 1928. This is characteristic of the situation in industry and in public life throughout the country. It is the belief of close students of this problem that the major cause of the present situation is the lack of leaders in this new profession. New York University has therefore decided this year to make its course for the training of public and industrial safety directors available to any interested man or woman showing qualities of leadership, irrespective of previous academic education. Ten free scholarships will be given.

The course will be given evenings at the Washington Square Branch of the University, and will be conducted in cooperation with the Museum of Safety and ten industrial and commercial associations which have been asked to designate scholarship students.

Students will be taken through the plants of members of the Museum of Safety and the various industrial associations where they may observe the technic of accident prevention.

BIOLOGICAL SUPPLY COMPANIES MERGE

PHYSICIANS and health officers will be interested in the merger of the H. K. Mulford Company and Sharp and Dohme, Inc. The latter has acquired all of the assets of the Mulford Company. An interest in Sharp and Dohme has been acquired by Alex. Brown and Sons associated with Chas. D. Barney and Company and Brown Brothers and Company.

The consolidation and merger craze has reached even biologicals and medical supplies. Physicians and health officers are interested in the stability and character of firms manufacturing and distributing such materials.

PERSONALS

DR. THOMAS J. SASSER has been appointed school physician in the Health Department of Charlotte, N. C.

DR. WALTER R. BERRYHILL of Belmont, N. C., has accepted an appointment on the faculty of the School of Medicine of the University of North Carolina.

DR. JULIUS F. MAUERMANN has been appointed health officer of Monroe, Wis.

DR. NELSON C. DYSART has been appointed as City Health Commissioner of Columbus, O. Dr. Dysart succeeds Dr. James A. Beer, who resigned.

ROBERT B. WATSON is the new Industrial Secretary of the Chicago Tuberculosis Institute, Chicago, Ill.

LEVERETT D. BRISTOL, M.D., Fellow of the A. P. H. A., who for the past year has been making a Health Survey of
